

II. Division:

The Macrolepidoptera
of the
American Region

6. Volume

The American Bombyces and Sphinges.

Phalaenae, Moths.

While the butterflies consist of only a few families, all closely related to one another with the exception of the Hesperidae, the very heterogeneous moths are composed of a long series of often very differently organised families, as has already been mentioned in the introduction to vol. 2.

The numbers of the families in the present volume do not agree with those of the corresponding volumes dealing with the other faunistic regions because the families are not all distributed over the entire globe.

Very little of a general nature can be said about the American Heterocera. There is a certain similarity to those of the Old World inasmuch as in the Eastern Hemisphere the duller coloured insects, which are adapted to tree-trunks and rocks, belong to the North, and the more brightly coloured diurnal ones to the South, this being also the case in America, where there is a distinct difference between the wintry North (Nearctic Region) and the hot South (Neotropical Region), the line of demarcation drawn between the two faunistic parts of the Western Continent in other works being quite justified. It is only for technical reasons that we have decided to deal with the whole of America in one single section and not in two separate ones. Only about 4000 forms of Macrolepidoptera are found in the countries north of Mexico, inclusive of the *Cossidae*, *Thyrididae* and *Sesiidae* hitherto counted as Macros (to which exception might be taken from a scientific point of view); while many times this number occurs in the scarcely larger Neotropical Region.

As the butterflies and moths of America live under the same physiographical and especially climatic conditions a similar effect must be expected in both divisions of Lepidoptera.

The brilliant colouring and metallic reflexions found among the *Castniidae*, *Syntomidae*, *Pericopiinae*, *Saturniidae*, *Sphingidae* and many *Geometridae* of Southern America are produced by the dazzling sunshine of the South in connexion with the dampness of the atmosphere; while northern forms are characterized by softer, duller and less conspicuous colouring. The schemes of markings also bear the stamp already described several times in the section devoted to butterflies, viz. in the North we find complicated patterns poor in contrast resembling bark and rocks, in the South brightly coloured decorative bands and spots on a deep black ground.

Very different methods must be adopted for collecting moths in the North and South of America. Collecting at the lamp is in the South sometimes quite successful, but may also yield nothing for months at a time. Baiting, on the other hand, is more successful in the North than in the South, where, if one has recourse to it at all, much larger quantities of the bait (large heaps of rotting fruit, puddles of strong-scented liquid, etc.) must be employed. Very little of a general nature can be said, and it is necessary for the collector to acquire special experience almost in every different district and in every family.

I. Section: Bombyces.

As regards the extent and subdivision of this group, we refer the reader to what is said in Vol. 2, page 3. The number of forms amounts to several thousands, not one-third of which — altogether not 1000 species — belong to America north of Mexico. In the extreme North the American fauna contains few and inconspicuous forms, some of which are identical or congeneric with Arctic species of the Old World. In the most northern latitudes the *Gynaephora* (*rossi* and *groenlandica*) head the list, and a few species in Labrador are so similar to those of the Arctic district of the Old World that many authors feel justified in including this part of America in the Palearctic fauna, their reasons for so doing being quite sound. In Canada and the United States also many forms occur parallel to those of the same latitude in the Eastern Hemisphere, but the number of species common to both Hemispheres diminishes more and more, whereas the congeneric species are still of frequent occurrence, though not to such an extent as among the Rhopalocera.

South of the Mexican deserts the character of the fauna alters so completely that only very few cosmopolitan forms remind one of the Eastern fauna, just as among the butterflies only the Painted Lady and the Camberwell Beauty extend south beyond the Neotropical boundary. The height of abundance is reached in the

Amazon Valley and the northern ranges of the Andes, southward to Southern Brazil, the number of forms diminishing first slowly, then with extraordinary rapidity, until in the still temperate region between 35° and 40° latitude mere fragments are encountered; one might say that nowhere on earth do the Lepidoptera decrease from a superabundance of forms so markedly and suddenly as in America between 30° and 35° latitude; and this is the case not only in South Chile, which is very poor in Lepidoptera, but also throughout Eastern Patagonia, a quite different open landscape. To find an adequate reason for this peculiar phenomenon is less easy than for another fact, viz., that the Bombyces and Sphinges are as good as extinct in Southern Patagonia; the fact alone that nearly all higher plants have been suppressed by the Cryptogamic flora, which flourishes here, is sufficient to account for the disappearance of all Bombyces and Sphinges, these being absolutely dependant on Phanerogams.

1. Family: Castniidae.

We have placed this peculiar group at the head of the moths, not because we consider it the most highly organised or specialised family, but because its insertion in any other place would doubtless cause those objections to be raised to which expression has always been given when the Castniids have been associated with some other family. Undoubtedly the *Castniidae* are a highly organised and recent group; that is evident from their bionomics. In their life-histories and habits they are so closely associated with the most modern plants and animals that it is difficult to understand how anyone can regard them as very slightly modified descendants of some already extinct or vanishing group of Lepidoptera. They can only be considered as ancestral inasmuch as their separation from the parent stock must have taken place at an early date, viz., when the distinction between butterflies and moths had not yet assumed the high degree of difference it has today. But they have adapted themselves to the present stage of evolution almost more than any other group. Their dress is often borrowed from undoubtedly recent groups of insects, the species of which are partly still in the process of evolution, i. e. from Danaids, Nymphalids, etc. The moth derives its nourishment from flowers which belong to the very latest developments of the flora, the larva feeding in semiparasitic or even cultivated plants. The Castniids are pronounced diurnals, the moths being most active in the brightest sunshine. As regards the senses, that of sight is most strongly developed, and the whole bearing of the insects shows distinctly that this sense alone is sufficient to enable them to carry out all the functions of life. They copulate by day, and are quarrelsome on the one hand while on the other given to playing together. They have an exact knowledge of locality, returning regularly to the places where they rest or feed, frequenting especially white or bright red flowers. They are untiring and adroit fliers, being undoubtedly superior on the wing to the other Lepidoptera which visit the flight-places.

The Castnias usually begin to swarm at about 10 o'clock, when the rays of the tropical are already uncomfortably hot, and show a preference for the honey of the blossoms of flowering trees. They rush wildly along, often from a considerable height, and by the violent impact of their hard body and with the sharp spurs on their long and stout legs drive away all small Diptera, Hymenoptera, and even Lepidoptera occupying the cluster or spray of flowers. The small wasps and especially Syntomids, which are nearly always found on such tree-blossoms, are simply knocked off, and the Castnia runs, buzzes and springs from flower to flower, dipping its strong proboscis rapidly into one corolla after another. They are most admirably adapted for fertilising flowers, and in spite of the smooth but very coarse scaling specimens are often met with which are entirely covered with pollen and therefore coloured according to their favourite flower.

After 11 a. m. the Castnias usually seem to be satiated and to have also slaked their thirst, and begin the business of propagation. For this purpose they select a place of vantage, any projecting branch being suitable; preferably they sit on the highest twig of dry leafless bushes, like the European dragon-fly *Libellula depressa*. I actually attracted these moths by attaching dry branches on to the tops of bushes so that the bare twigs projected well into the air. Species like *C. mygdon*, *decussata* and *amycus* are often also seen fluttering around the heaps of faggots piled up when the ground is being cleared. From this look-out the male keeps watch so attentively that it is difficult to approach it. Only occasionally I succeeded in getting so close to specimens of larger species, such as *C. schreibersi* and *fonscolombe*, that I could observe them minutely. They keep their wings folded in roof-shape, sit with the anterior portion of the body slightly raised, and when flying off bounce into the air, probably making use of the elastic tibial spurs. I was able to observe that they turned their head slightly towards humming-birds, etc., flying past them, as does a mantis or dragon-fly; their long thin neck enabling them to make this movement so unusual in Lepidoptera. This observation supports my opinion that in the preliminaries to copulation the sense of sight comes into play almost exclusively. The peculiar knotted antennae do not seem to be used until a later stage in the mutual approaching has been reached. The male Castnia rushes with wild and overpowering impetuosity at every insect remotely resembling itself. I once saw *P. atymnius* fight the very strong *Ageronia amphinome* and molest the latter until they left the spot, an open

patch in the woods, the *Castnia* remaining in sole possession. Moths also and even small birds were driven away, and this continued until a ♀ of the same species was seen. The ♂ follows the ♀ in very rapid pursuit; in many species, especially those of the *Gazera* group, around the tree-tops or through the sparse foliage of single palms and Cecropias, in the case of *C. atymnius* and *cochrus* along the wood-paths. Copulation I have only been able to observe more closely in *atymnius*. The wary ♀ flies into the bushes and settles on a vertical branch, with its head upwards and its wings open ready for flight; the ♂ sits about half a yard lower down, minutely observing the ♀. On the slightest provocation the latter flies off, and the ♂ rushes after it in continuous headlong pursuit. In the air they often touch each other, until they suddenly fly apart. I have never seen a pair belonging to this family in copulation and therefore am convinced that normally this act takes place while the insects are on the wing.

Ovipositing has probably never been observed. The food of the larva is found to be the fruit of trees, cane-stalks, or orchids, the larva boring its way into the roots of the last-named. Orchids, especially the larger species, are not common, and as they occur chiefly in the tops of high trees it is very difficult for the collector to reach them. The healthy bulbs of the rarer orchids are worth much more than the *Castnia* larvae living in them and the collecting of larvae is therefore neither very successful nor remunerative. However, as is mentioned under *Castnia*, some details of its life-history are known; living *Castniae* have even been caught in Europe, a proof that the pupa is able to withstand the dangers of transit.

In most cases the *Castniae* are very difficult to catch; they are most easily captured at flowers. I often obtained good specimens of *C. pallasia* and a few *decusata* at flowering trees. But when in the net the insects rush about so wildly that it is very rarely possible to secure them in perfect condition. The many defective specimens one meets with in nature prove that the violent behaviour of the moth is injurious to their wings, and that the latter, almost equalling cardboard in stoutness, suffer in the fights and wild races through the bushes.

Larger species are so strong and make such efforts to escape that one can scarcely hold them in ones fingers. *C. schreibersi* for instance I could only hold by squeezing the thorax so hard that the woolly covering of the underside was rubbed off, the insect at the same time stabbing me quite severely with the spurs of its hindtibiae. The *Castniae* are, moreover, very tenacious of life, which is rarely the case in groups of insects containing mimetic forms. Their skeleton is unusually hard and fairly tough, so that one often has to use all ones available strength to squeeze the thorax sufficiently to lame the moth; only tobacco-juice and injections of ammonia kill surely and swiftly, as they do other tenacious insects.

The scaling of the wings also suffers very easily. The *Castniae* are covered with a very dense but coarse scaling, and the single scales are of an extraordinary size, being the largest of any moth or butterfly I know. On account of these large scales the wings often look like a piece of embroidery in which each single stitch is visible. Bare stripes therefore easily occur, especially on the median and costal veins, and the unusually long fringes of the wings are also easily worn.

The *Castniae* are almost all of large size, some of them being very large moths; *C. daedalus* and *pylades* reach 180 mm expanse, and even the smallest known species, such as *marcelserres* and *amyceus*, attain medium size. In colour they are exceedingly gaudy, red being predominant. On the dark patches of the wings there is often a beautiful gloss, which shows up marvellously, especially when the insects sit in the glaring sun, as is their custom. In spite of this the forewings often imitate a crinkled dry leaf or the fruit of a tree, and it is worthy of note that the species so protected allow one to approach, as though they relied on this resemblance, while the species without this protective colouring, e.g. some forms of *Gazera*, spend the hours when they are not on the wing hidden away in the bushes, and rush away when they find themselves discovered. When on the wing many species resemble huge *Catocalas*, but far surpass the latter in rapidity of flight.

As will be explained below, we here only accept one genus, divided into several groups. It is almost exclusively confined to the tropics of America, where it is distributed from Argentina and Paraguay in the South to Mexico in the North without reaching the frontier of the United States. We have dealt with the Indo-Australian "Castniidae" and their probable affinity in vol. 10, p. 3, and with the African genus placed here in vol. 14, p. 3. About 160 forms are known from America, all of which are easily distinguishable, many, however, being extremely rare in collections. Perhaps some species spend their whole life in or above tree-tops, as it is there that they find all they need both as larva (fruits or orchid-roots) and as moth (which are essentially visitors of flowers).

Head fairly large, on a thin neck, frons broad posteriorly, narrower anteriorly. Eyes naked, large, prominent. Palpi of medium length, appressed to the head and rarely projecting beyond it. Antennae very strong, gradually swelling to form an elongate club which ends in a small whip. Thorax broad, stout, with a hard shell and covered with smooth fluff and large scales. Legs strong but not conspicuously stout, forelegs

rather short, middle and hind legs long, the hind tibiae with two pairs of strong spurs with which the insects can scratch severely. Abdomen strong, long, in the ♂ only slightly thinner than in the ♀, in which it bears a protrusible ovipositor. Wings with entire margins, without teeth or other appendages, obtusely triangular (forewing) or nearly circular (hindwing). Veins very regular and almost parallel, the cell short, especially that of the hindwing, both cells traversed by veins. On the forewing the subcostal branch 1 originates close beyond the base of the wing, 2 directly behind the middle of the cell, 3 before and 4 at the upper angle of the cell; between the posterior median branch and the submedian there is always an intermediate vein which sometimes originates at the base, but often begins close before the middle of the wing. The submedian is sometimes connected by a bar with the hindmarginal vein, if the latter is present. In detail the venation shows numerous variations, especially in the shape of the discocellulars of the forewing. Characteristic of the insects is the remarkably uniform direction of the always very long branches of the veins, which run exactly parallel one with the other.

The larvae of only very few species are known; they are predominantly bare, with short bristles only on the back of the segments, with soft skin, strong nuchal plate and small retracted head. The six thoracical legs short, the eight abdominal legs broad, the anal pair elongate. They live in stalks, fruits or bulbs. Pupae elongate-ovate, stumpy; eyes prominent, limb-cases loosely connected, back of abdomen with strong belts of hooks; sometimes short bristles cover the larger portion of the surface of the pupa; many species in long silk-lined tunnels in or on the ground.

Genus: **Castnia** *F.*

The genus *Castnia*, which is here treated in the usual broad sense of the name, contains those forms which may be regarded as the most typical representatives of the family *Castniidae*. It will therefore suffice for our purposes to draw attention to the description of the family without giving a special systematic characteristic of the genus, particularly as only one genus of *Castniidae* occurs in the region with which we are dealing. Cf. also what was said about the *Castniidae* in Vol. X. p. 1 of this work. As has already been mentioned in that place the attempts which have been made to split up the genus *Castnia* cannot be regarded as successful, and later authors have therefore retained the genus in its original conception, only one of the separated genera, *Gazera*, being occasionally dealt with as distinct from *Castnia*. In the following pages I have also attempted to keep the species of *Gazera* separate, but only as a group, as the distinctions do not appear to me to be sufficiently trenchant to be considered of generic value. My further attempts at dividing *Castnia* into smaller groups have only the purpose of rendering the arrangement more lucid and the naming of the forms more easy, and is of no importance as regards nomenclature. It is difficult as yet to draw any conclusion as to the relationship and the systematic arrangement of the various species of Castniids, especially because we know scarcely anything about the early stages of these moths.

I. **Castnia** *s. str.*

Forewing more or less broad and triangular.

(Species which are not known to me in nature are not included in this survey unless special information as to their relationship is given in the literature, but have been added in the appendix, p. 16. 17).

A. Forewing with straight whitish median transverse band between the anal angle and the middle of the costa and whitish subapical markings. Hindwing with small white spots.

C. daedalus *Cr.* (= *cyparissias* *F.*) is a species occurring in Guiana and the Amazon district, well characterised by its size (expanse up to 180 mm). In its scheme of markings similar to *geron*, of which a figure is given; ground-colour above dull black, slightly suffused with olive, in the hindwing with two rows parallel to the margin of white or yellow rounded spots. — The larva lives in Bananas.

C. geron *Koll.* (1 a) is a much smaller species occurring in Brazil, in which the inner one of the two rows of spots on the hindwing is only present in the costal half of the wing.

C. preissi *Stgr.* (1 a), from the Amazon Valley, has only the anterior spot of the inner row; in the forewing three light subapical spots.

B. Forewing with narrow white postmedian band parallel with the margin; hindwing with red, yellow or blue band, with or without red spots.

C. cacica *H. Schöff.* (1 b), from Central America and Columbia, is most easily distinguished from the following

C. papilionaris *Wkr.* (1 a), from Bogotá, by the markings of the hindwing. Like *DRUCE* (cf. *Biol. papilionaris*).

Centr. Amer., Het. 1, p. 25). I fail to find the white discal spot on the specimens of *cacica* before me which the species should have according to the original figure copied on plate 1. The number of red sublimbal spots on the hindwing is five in the typical form, but some specimens before me have only four (fa. *procera* Bsd.) and sometimes they may be merged together to form a band (ab. *bivittifera* ab. nov.). The width of the red band on the hindwing is also rather variable, and sometimes this is partly separated into spots (ab. *macula* ab. nov.).

In contradistinction to our figure the specimens of *papilionaris* before me have the forewing and hindwing about equally dark, the light discal spot on the forewing being smaller.

hodeei. **C. hodeei** Oberth. (1 c), from Colombia, is most easily distinguished from *cacica* by the different colour and shape of the band of the hindwing.

C. Forewing with light, straight, median, transverse band between anal angle and middle of costa, with or without whitish subapical spots; hindwing with broad, white, transverse band, narrowed or interrupted anteriorly, with or without light submarginal spots.

atymnius. **C. atymnius** Dalm. (= *spixi* Perty) (2 b), widely distributed in South and Central America, varies considerably, and its ♀ is sometimes very like the following species (*C. humboldti*); the latter, however, always differs in having the apical half of the hindwing red. The ♀♀ differ from the ♂ figured especially in the presence of light subapical spots similar to those of *humboldti*. — In fa. *defasciata* ♂ form. nov. the band of the forewing, which is usually white, is only slightly indicated by a greyish shadow. In fa. *feminis* ♂ form. nov., there are light subapical spots on the forewing like those of the ♀, but smaller and less sharply marked (1 ♂ from Bahia); the white band on the hindwing of this specimen is remarkably broad anteriorly (5 to 6 mm). — In *salasia* Bsd., from Mexico, the fringes are said to be uniformly black.

humboldti. **C. humboldti** Bsd. (1 c), from Colombia and Central America, is altogether larger than *atymnius*; I do not agree with BOISDUVAL, who states that the wings are more pointed apically than in the preceding species. In the ♂ the light subapical spots of the ♀ seem always to be at least faintly indicated. — In *rufolimba* form. nov. (1 c) the subapical spots on the upper side of the forewing are smaller and further distant from the transverse band, on the underside of the hindwing the white transverse band is much narrower (always ?) than above. — *brunneata* form. nov. (1 c) has both wings reddish brown above.

futilis. **C. futilis** Wkr. is a somewhat questionable species from Central America, which seems to differ from *humboldti* in the slightly inferior size and lighter, more reddish or brownish, colour above and below; the ♀, moreover, has the subapical spots of the forewing quite diffuse (differing therein as well as in its somewhat smaller size from the very similar form *brunneata* Strand of *C. humboldti*). — The specimen figured by DRUCE in Biol. Centr. Amer. Het. tab. 4, f. 5 as *futilis* I should consider a ♂ of *humboldti*; but SCHAUS in 1911 describes this form as a new species under the name of *drucei*, stating the type of *futilis* to be a form of *atymnius*.

licus. **C. licus** Drury (= *aurantiaco-maculatus* and *plumbeocoerulescens* Goeze) (2 a) is widely distributed in South and Central America, and is very variable. — The forms *licoides* Bsd. (2 a) and *licoidella* form. nov. (2 b) are most easily distinguished by the different markings on the forewing; *pauperata* form. nov. is otherwise like *licoidella*, but has only two distinct reddish yellow spots on the hindwing (in cellules 2 and 3) (1 ♂ from Surinam). — The larva feeds in sugar-cane and is very destructive (cf. MARLATT in: Bull. U. S. Dep. Agric. No. 54 (1905), p. 71 to 75, t. 4).

D. Forewing as in group B, hindwing with white median and red marginal area spotted with black.

dalmanni. **C. dalmanni** (recte: *dalmani*) G. R. Gray (= *grayi* Bsd.) (2 c) occurs in Brazil and is distinguished i. a. by the pointed forewing and its straight distal margin.

E. Forewing with two white straight transverse bands almost vertical to costal margin and with a light subapical marking; hindwing with red and black markings.

icarus. **C. icarus** Cr. (2 d) is widely distributed in Brazil and Guiana; whether this is the case also in Central America still requires confirmation. — *invaria* Wkr. differs in the discal spots of the hindwing being almost obliterated. Brazil.

penelope. **C. penelope** Schauf. "Very similar to *icarus* in colour and markings, but the upperside altogether paler, the marking of the hindwing brown instead of black, the outer transverse band of the forewing and the white spots of the hindwing almost obsolete; on the underside the three bands of the forewing well developed; otherwise opalescent like *icarus*, of which it is perhaps only a variety". Lat.: 78 mm. Brazil.

F. Forewing with one or two yellowish transverse bands about vertical in position, with or without subapical spots; hindwing red and black, with or without yellow markings.

evalthe. **C. evalthe** F. (= *dardanus* Cr.), from South and Central America, occurs in two forms. I consider the principal form the one figured in DONOVAN's Ins. India t. 22, which differs from the form *evalthoides* form. nov. (3 a) in the bands of the forewing being brighter yellow and both much narrowed posteriorly.

while the proximal one of these bands here is about 7 mm broad anteriorly, in *evalthoides* it only attains 4.5 mm. In *evalthoides* the yellow median spots of the hindwing are merged together to form a continuous band, and in *evalthe* they are separate from one another, the red marginal spots of the latter form are seven in number and smaller, at least anteriorly, than in *evalthoides* (3 a). I consider Bolivia the typical locality for the last-named form.

C. viryi *Bsd.*, from C. America, differs from *evalthe* especially in the absence of the distal transverse *viryi*. band of the forewing.

C. euphrosyne *Perty* (= *pertyi* *Buchecker*) (2 d), from Brazil, differs from *evalthe* especially in the different shape of the yellow and red markings of the hindwing. *euphrosyne*.

C. syphax *F.* (= *harmodius* *Stoll*) (2 d), from Brazil and Cayenne, has no yellow markings on the hind- *syphax*. wing, and a curved row of spots takes the place of the distal band of the forewing.

C. mathani *Oberth.* (3 e), from the Amazon, has the band of the forewing obsolescent, but the subapical spots sharply defined; the spots on the hindwing small. *mathani*.

G. Forewing blackish with two obsolescent light transverse bands, usually connected in the middle, the proximal one of which is elbowed (open proximally). Hindwing at least with light median marking. Large insects.

C. schreibersi *Mikan* (= *latreille* *Godt.*, *ctesiphon* *Hbn.*) (3 b) is in its principal form characterised by the bluish white spots of the hindwing, but these are absent in the form **actor** *Dalm.* — Brazil. *schreibersi*. *actor*.

C. zerynthia *G. R. Gray* (= *langsдорffi* *Mén.*) (3 a), from Brazil and Bolivia, judging from the six specimens before me, is darker on the forewing, more blackish (only slightly suffused with green) than our figure. *zerynthia*.

H. Forewing greyish or brownish with markings similar to those of G, and more or less obsolete. Hindwing with two or three rows of whitish or reddish spots which are rather close together and sometimes assume the shape of bands. Small or of medium size.

C. phalaris (*F.*) *Godt.*, *Bsd.* (= *mygdon* *Ww.* p. p., *mimon* *Hbn.* (?)) (4 a, as *mygdon*). In determining this species I agree with BOISDUVAL, not WESTWOOD, and, like the former, distinguish *mygdon*, although not as a distinct species. The insect figured by WESTWOOD as *phalaris* is *subvaria* *Wkr.*, which I consider with KIRBY as a distinct species; I do not understand, however, why KIRBY quotes WESTWOOD's figure under his (KIRBY's) *phalaris*. And as GODART, the first monographer of the group, applied the name *phalaris* to the same species which BOISDUVAL also called *phalaris*, it follows that the name must be retained for this form and no other. — From **mygdon** (*Dalm.*) *Bsd.* (*Westw.* p. p.) *phalaris* is distinguished by its (usually ?) larger size: according to BOISDUVAL up to 120 mm. in expanse; the largest specimen before me measures 95 mm., *mygdon* only 55 to 70 mm; the spots of the two transverse rows on the hindwing are white in *phalaris*, occasionally with a yellowish edge, while in *mygdon* they are yellowish; within the proximal one of these rows light spots are usually visible, this appearing rarely to be the case in *mygdon*; on the underside also the spots of the hindwing are usually white and sharply marked, while in *mygdon* they are yellowish and diffuse; the white markings of the underside of the forewing large and sharply marked, in *mygdon* yellowish. Entire colouring of *mygdon* darker. — Both forms described from Brazil. *phalaris*.

C. subvaria (= *phalaris* *Westw.* nec *F.*) (4 a, as *phalaris*) has actually the wings of the same shape as the form **subvariana** *form. nov.* (4 a, as *subvaria*), our figure of *subvaria* being inexact in this respect. **dionaea** *subvariana*. *Hpffr.* is a smaller form (length of forewing 26 mm.). — Brazil. *dionaea*.

C. albofasciata *Schauf.*, „Larger than *mimon*, above with the same markings, but the forewing on each side of the brown transverse band with a narrow white edge filled in with diffuse white scaling, hindwing with three rows of white spots edged with black and cinnamon-brown, similar to those of *phalaris*, but the white colour predominant; underneath very like the preceding (perhaps only its ♀?). Lat. 88 mm.” — Brazil. *albofasciata*.

C. sora *Druce*, from Paraguay, has the forewing dark brown, similar in markings to *C. mygdon*, but darker; fringes brown. Hindwing black; a large dark orange yellow spot at the apex of the cell, and two bands of large dark orange yellow spots from the costal margin to the anal angle, the first band, just below the cell, the second along the margin, fringes yellow. Body and extremities dark brown, anus yellow. ♂ 82.5, ♀ 95.4 mm.

C. chelone *Hpffr* (2 e), from Mexico, is characterised by the greyish colour of the forewing and the peculiar curved and almost band-shaped rows of light spots on the hindwing. *chelone*.

C. argus *Bsd.* (6 a) recalls *phalaris*, but can be easily distinguished by the rows of red or reddish yellow spots of the hindwing. — Brazil. *argus*.

C. orestes *Wkr.* (= *umbrata* *Mén.*) (3 b), from Brazil and Venezuela, resembles the otherwise so different *zerynthia* (3 a) in the markings of the abdomen and hindwing. — **leopoldina** *form. nov.*, from Leopoldina *leopoldina*.

in Espirito Santo (Brazil), differs in the strongly reduced white band of the hindwing, which is only 2 to 4 mm. broad, separated into elongate spots, and does not reach the inner margin. One specimen 80 mm. in expanse (type), another only 58 mm., both ♂♂.

I. Forewing blackish with grey irregularly angulate transverse band and grey spot at the inner angle. Hindwing black with two white or yellow and one (median) red row of spots sometimes resembling a band.

- pallasia*. **C. pallasia** Esch. (= *breccourt* Godt., *ardalus* Dalm.) (4 c). According to my researches the synonymy of this Brazilian species, usually called *breccourti* Latr., is as follows: The name *pallasia* has priority; it was published in 1821, while *breccourt* dates from 1824, the date 1819 on the title-page of the respective volume of the "Encyclop. méthod." only being correct for the first 328 pages of the volume (cf. SHERBORN and WOODWARD in Proc. Zool. Soc. Lond. 1893 and 1899). — According to the description of *breccourt* this form is distinguished from *pallasia* by the band on the upperside and the sublimbal spots on the forewing beneath being white instead of dark grey; the proximal white band on the hindwing is apparently not traversed by black veins in *breccourt*, the band being expressly described as "continue", while the figure of *pallasia* distinctly bears such black veins. Unfortunately the description of *breccourt*, stated moreover to be taken from a unique specimen, is evidently not exact enough to enable us to find out from it differences, if any, between *breccourt* and true *pallasia*; we must therefore place *breccourt* Godt. as a synonym of *pallasia*. On the other hand, *breccourti* Preiss is doubtless a form distinct from true *pallasia* (according to the description of *breccourt*), differing above all in the absence of the white band of spots on the hindwing. As this band is plainly described as present in "*breccourt*", the latter name cannot be used for PREISS's form, which must be renamed: **umbratula** nom. nov. (4 c) with the synonym: *breccourti* Preiss nec Godt. — The form figured by WESTWOOD in his monograph of *Castnia*, plate 30, fig. 2, is probably not specifically different from *pallasia*, as he also assumes; but this form differs so strongly from true *pallasia* in the very broad light band of the hindwing and in the likewise broad band on the forewing, which, moreover, is not incised outwardly in its anterior half, that it deserves a name: **lativittata** form. nov. (4 b). — Specimens of both sexes of *umbratula* and true *pallasia* are before me; the difference therefore is not sexual.
- satrapes*. **C. satrapes** Koll. (4 b), from Brazil, differs from *pallasia* inter alia in the light marking of the forewing being interrupted in the middle; the var. **catharina** Preiss (4 b) differs in the median band of the hindwing being light yellow instead of orange. The fact that red spots are not present in our figure of *catharina*, while they are marked in that of *satrapes*, is possibly due to a difference of sex: probably the ♀♀ of both forms always bear these spots, while they are only occasionally present in the ♂♂. The ♂-form resembling the ♀ in colour I name **rufimaculata** ♂-form. nov.; if the yellow band of the hindwing is not broken up by black veins we get the form **aberrans** ♂-form. nov. The ♂♂, at least of the variety *catharina*, are therefore dimorphic; whether dimorphism also obtains in true *satrapes* I can unfortunately not say, as I have only 2 ♀♀ before me. — *aberrans* comes from Leopoldina; from Rio Grande do Sul I have both *rufimaculata* and true *satrapes* ♂♂. The type of *rufimaculata* is 97 mm. in expanse. In both aberrations the longitudinal and transverse bands of the forewing are connected.
- catharina*. **C. catharina** Preiss (4 b) differs in the median band of the hindwing being light yellow instead of orange. The fact that red spots are not present in our figure of *catharina*, while they are marked in that of *satrapes*, is possibly due to a difference of sex: probably the ♀♀ of both forms always bear these spots, while they are only occasionally present in the ♂♂. The ♂-form resembling the ♀ in colour I name **rufimaculata** ♂-form. nov.; if the yellow band of the hindwing is not broken up by black veins we get the form **aberrans** ♂-form. nov. The ♂♂, at least of the variety *catharina*, are therefore dimorphic; whether dimorphism also obtains in true *satrapes* I can unfortunately not say, as I have only 2 ♀♀ before me. — *aberrans* comes from Leopoldina; from Rio Grande do Sul I have both *rufimaculata* and true *satrapes* ♂♂. The type of *rufimaculata* is 97 mm. in expanse. In both aberrations the longitudinal and transverse bands of the forewing are connected.
- rufimaculata*. **C. rufimaculata** ♂-form. nov.; if the yellow band of the hindwing is not broken up by black veins we get the form **aberrans** ♂-form. nov. The ♂♂, at least of the variety *catharina*, are therefore dimorphic; whether dimorphism also obtains in true *satrapes* I can unfortunately not say, as I have only 2 ♀♀ before me. — *aberrans* comes from Leopoldina; from Rio Grande do Sul I have both *rufimaculata* and true *satrapes* ♂♂. The type of *rufimaculata* is 97 mm. in expanse. In both aberrations the longitudinal and transverse bands of the forewing are connected.
- aberrans*. **C. aberrans** ♂-form. nov. The ♂♂, at least of the variety *catharina*, are therefore dimorphic; whether dimorphism also obtains in true *satrapes* I can unfortunately not say, as I have only 2 ♀♀ before me. — *aberrans* comes from Leopoldina; from Rio Grande do Sul I have both *rufimaculata* and true *satrapes* ♂♂. The type of *rufimaculata* is 97 mm. in expanse. In both aberrations the longitudinal and transverse bands of the forewing are connected.

I. Forewing brown with very obsolescent light, irregular markings, sometimes very difficult to perceive; hindwing red with black transverse bands, in *hegemon* also with white or yellow central band. The ♂♂ of *thais* and *marcelserres* have dark hindwings with lighter markings only in the marginal area.

- ciela*. **C. ciela** H.-Schäff. (4 d), from Brazil, probably rarely has the markings of the forewing as distinct as they are in our figure, the median area of the hindwing also is usually not so light, but slightly suffused with red.
- fabricii*. **C. fabricii** Swains. (4 e), also from Brazil, is characterised by the wedge-shaped submarginal spots of the hindwing, also by the simple band of the forewing and its discocellular spot, as well as by the dark red basal area of the hindwing. — Must be a very rare species. Typical locality "Diamond district of Brazil".
- hegemon*. **C. hegemon** Koll. (5 b), from Brazil, cannot be confused with any other species of this group, chiefly on account of the markings of the hindwing.
- marcelserres*. **C. marcelserres** Godt. (= *thais* Wkr., *fabricii* Godt.) (4 e) is in the ♂-sex a small inconspicuous insect (fig. cit.); the ♀ has light red hindwing marked with three bands of black spots and is larger (about 70 mm. in expanse). The ♂♂ vary much in size, the specimens before me measuring from 37 to 62 mm. in expanse. The smallest ♂-form may be distinguished as **pusillima** form. nov. — Brazil, Bolivia.

thais. **C. thais** Dru. (= *chrenus* F., *nicon* Hbn., *morphoides* Wkr., *thalaira* Godt., *jonesi* Buchecker) (8 a) in the ♀ is very like *C. marcelserres*, but the forewing bears a broad, straight, almost parallel-sided dark band directed towards the distal margin and anal angle, while the corresponding band in *marcelserres* is curved, irregular, in parts much narrowed, almost or entirely interrupted in the centre and directed towards the inner margin. A light median transverse band is present in the forewing of both species: in *thais* it is broad, sharply marked, curved concavely proximally, in *marcelserres* narrow, only sharply marked on its outer side, straight, vertical

to the inner (hind) margin. Moreover, *thais* is larger, etc. The hindwing of the ♀ of *thais* is black in its apical half, with two rows of red spots, in *marcelserres* red with three rows of black spots. The ♂ of *thais* has blackish blue hindwing bearing a reddish yellow marginal band in the anterior half. — Brazil.

C. inornata Wkr. ♀. Rust-reddish brown, fawn-colour below. Frontal tuft porrect, lanceolate, projecting *inornata*. beyond the head. Tip of antenna light grey. Abdomen blackish above, not reaching the anal angle, each segment with a yellow transverse spot. Forewing with two irregular oblique brown bands, diffuse on their outside, and having between them a kidney-shaped dark grey spot with a brown edge; below with two irregular dark brown bands beyond the centre, the first in spots, the second strongly abbreviated posteriorly, marginal area (below?) fawn coloured. Hindwing beneath with an irregular, abbreviated, rust-coloured line straight across the centre, at the costal end enclosing a whitish spot. Length of body 10 lines, expanse of wings 31 lines. Is said to be allied to *C. thais*. Patria not given. Unknown to me.

K. Similar to the preceding group, but the forewing with subapical vitreous spots.

C. inca Wkr. (= *clitarcha* ♂ *Westw.*) (5 a) extends from Mexico to Venezuela and is distinguished inter *inca*. alia by the markings of the hindwing, which bears at least in the ♂ an isolated black spot at the costal margin (5 a). In *staudingeri* Druce (5 a) the black marginal band of this wing is strongly reduced or entirely obsolete *staudingeri*. and therefore connected with the preceding band only at the anal angle, being anteriorly divergent from the outer margin and here usually separated into spots, the forewing appears lighter and more unicolorous than in *inca* and the hindwing is partly yellow (5 a). It is not improbable that *staudingeri* is a form occurring only in the ♀-sex. (There are nine specimens of *inca* before me, all ♂♂, and three of *staudingeri*, all ♀♀.) The only ♀ before me which I consider the ordinary ♀ of *inca* differs from *staudingeri* principally in the absence of the yellow patch in the hindwing. — **hondurana** ♂-form. nov. is smaller (expanse 58, length of wing 32 mm.) and in *hondurana*. the hindwing rather like the ♀ in colour; the black antelimbic band of the same is not connected with the margin even at the anal angle. Honduras.

C. clitarcha Ww. (♀; *clitarcha* ♂ Ww. belongs to *inca*!) (8 e), from Chiriqui, is in the ♂ very like the preced- *clitarcha*. ing, but the black marginal band of the hindwing also covers the margin, while the real marginal band of *inca* is reddish yellow (which is unfortunately scarcely distinct enough in our figure), the size is more considerable (expanse of wings about 110 mm.), the apex of the wing has three vitreous spots, the central one of which is large and elongate, etc. The largest ♀ before me measures 120 mm; the markings of the hindwing are, like those of the ♂, similar to those of *inca* with the exception of the marginal markings; the forewing bears a median and a postmedian greyish yellow transverse band in the costal half. — **orizabensis** form. nov. (8 d), from Orizaba, *orizabensis*. I place with *clitarcha* with a query, as it is intermediate between *inca* and *clitarcha*.

C. ahala Druce (4 e), from the Amazon, is very like the ♀ of *inca*, but smaller and inter alia differs *ahala*. in the narrow dark oblique band of the forewing.

C. palatinus Cr., from Guiana and Brazil, resembles *inca*, but the vitreous spots of the forewing are *palatinus*. smaller, the light median band of the hindwing is white in its posterior half, the black marginal band only encloses very small spots, which are often also reduced in number, etc.

C. boisduvali Wkr. (= *herrichii* H.-Schäff. ♀) (4 d) differs in the ♀ from the ♂ figured in that every- *boisduvali*. thing which is red in the latter is yellow in the former, as is also the abdomen. Widely distributed in S. America. — **besckei** Mén. ♂ differs from the normal ♂ in the fewer markings on the underside of the forewing and the lighter *besckei*. red colour on the upper side of the hindwing. Bahia.

C. papagaya Ww. (4 d). Forewing in the basal half yellowish with a greenish sheen, brown base and *papagaya*. brown kidney-shaped transverse costal-discocellular spot; marginal area brown; before the centre of the inner margin to the costal margin close before the apex of the wing a blackish brown band which at both ends is strongly widened triangularly and anteriorly encloses a vitreous spot divided by the dark veins. Hindwing red with bluish black basal area and two narrow black transverse bands, the veins being broadly edged with black in the marginal area. Expanse of wings 97 mm. Papagaya. — There is a ♀-form before me from Rio Grande do Sul which differs in that the dark band of the forewing is quite interrupted in the centre, and the two black bands of the hindwing are connected by the broad black dusting of the intermediate veins so that the red colour between them appears as isolated red spots; the black dusting on the veins in the marginal area however is very narrow and indistinct. I name this form **grandensis** form. nov. *grandensis*.

C. menetriesi Bsd. Is compared with *boisduvali* and *dalmani*. Forewing blackish brown with two deep *menetriesi*. black transverse bands, the anterior one of which is bifid, being connected with the other by a lateral branch; in the costal area two lighter smears. Hindwing black, towards the centre with a large yellow transverse spot. and margined with four or five orange spots. — Brazil.

C. superba Strand (5 a), from Chanchamayo (Peru), occupies a unique position on account of its broad. *superba*. deep black parallel-sided band on the hindwing contrasting sharply with the light yellow one beside it.

Beneath, the light median bands of both wings appear alike in colour, being of the same shade as that on the upperside of the hindwing, the dark areas are reddish brown, only being black in the anal angle of the hindwing and the posterior half of the postmedian band of the forewing.

L. Forewing blackish with two greyish yellow, irregular curved transverse bands directed slightly obliquely towards the costal margin. Hindwing black or blackish with red sublimbal band bearing black spots. Large insect.

pylades. **C. pylades** *Stoll* (5 c), occurring in Cayenne, Brazil, etc., is on the whole darker than our figure indicates, and the greenish sheen seems usually to be less distinct. — The larva lives in bananas.

M. Both wings blackish with light markings consisting of numerous spots or narrow bands, recalling the pattern of *Neptis*.

galinthias. **C. galinthias** *Hpfrr.* (6 a), from Brazil, has the basal area of the hindwing below whitish, and the ground-colour above is usually darker, more blackish than in the case of our figure.

strigata. **C. strigata** *Wkr.* (= *discoidalis* *Buchecker*) (6 b), from Brazil, sometimes has the whitish band originating in the middle of the costa separated into spots in the distal half, or, one might say, it is absent there, while the white spots in the apical half of the wing are larger and more numerous than in our figure of **godarti** *Mén.* — The larva is said to live in orchid-roots.

decussata. **C. decussata** *Godt.* (6 a). Brazil. A large ♀-form (expanse 91 mm.) differs in that the anal angle of the hindwing bears a reddish yellow spot and that the larger basal half of the underside of the hindwing is pure white. *fulvipygga.* I name this form **fulvipygga** *form. nov.*

N. Wing white, with black marginal marking.

cronis. **C. cronis** *Cr.* (6 a) is distinguished from the other Pierid-like true Castnia, viz:

cronida. **C. cronida** *H.-Schäff.* (6 c) very easily by the differences shown in the figures. Both occur in Guiana.

O. Small brownish insects, with two narrow whitish transverse bands, partly divided into branches and directed almost vertically towards the costal margin, with light innermarginal band, and some of them with a central longitudinal one. Hindwing black, with red and white markings.

huebneri. **C. huebneri** *Latr.* (= *sternbergi* *Koll.*, *castnioides* *Buchecker*) (6 b). Brazil. In true *huebneri* the two light bands of the forewing and the light median row of the hindwing white (purer white than in our figure), and the fringes usually pure white in the apical half. — In fa. **impura** *form. nov.* these markings are dirty ochreous and the fringes uniformly greyish brown, as well as the ground-colour of the entire wings above somewhat darker. — If in addition the row of light spots in the dark area on the hindwing is entirely or almost entirely obsolete, we have the form **indecora** *form. nov.*

uruguayana. **C. uruguayana** *Burm.* (6 b). Characterised inter alia by the light longitudinal stripes on the thorax dorsally, varies considerably in the markings of the hindwing, and has lighter and darker transverse bands on the back of the abdomen, which are not visible in our figure. — A form of which a ♂ is before me is distinguished by the proximal red transverse band of the hindwing not being connected with the median one, while the latter only once touches the distal one, moreover there are no isolated light spots between the bands of the forewing. To this form, the exact locality of which is unfortunately not known to me, I give the name **separatula** *form. nov.*

P. Ground-colour of wings reddish, brown or orange, hindwing with narrow black marginal band having light spots, forewing with one or more small subapical vitreous spots (with the exception of *bogota*).

therapon. **C. therapon** *Koll.* (= *therapion* *Bsd.*, *paradoxa* *H.-Schäff.*) (7 a), from Brazil, has the same ground-colour beneath as on the hindwing above; the black marginal band on the underside of the latter has two rows of light dots below. The larva lives in *Oncidium crispum* (cf. SNELLEN, Tijdschr. v. Ent. 38, p. 9) and *Catasetum* sp. (cf. KLUG in Abh. Ak. Wiss. Berlin, p. 245 to 257, 1848).

rutila. **C. rutila** *Fldr.* (7 a), also from Brazil, has no black marginal band on the underside of the hindwing, but a sublimbal row of brown spots.

bogota. **C. bogota** *Strand.* ♂. Forewing reddish brown, darker at the discocellular, the fringes white, at least posteriorly, inner margin narrowly black. Beneath orange-yellow in the middle and in the dorsal region, more reddish basally; a band about 2 mm broad at the costal margin becomes gradually broader from the middle to the margin, attains a width of 7 mm. at the apex of the wing and then becomes gradually narrower posteriorly reaching to vein 2, from where it continues to the inner margin as a black band thrice deeply indented on its inner side. In the marginal area veins 3 to 5 are also dusted with black. Discocellular spot deep black, in an oblique position and 2 × 1.2 mm. in size. Hindwing above and below orange with deep black marginal band which is 5 mm. broad, but becomes somewhat narrower anteriorly and is minutely dentate on its inner side; above in each of cellules 1 to 4 it encloses a small spot with a bluish sheen; similar but still larger spots are also present beneath, where the band is truncate between veins 5 and 6. Body above blackish, below orange as are also the legs. Expanse 42, length of wing 25 mm. — Bogota (Type in coll. W. NIEPALT).

Q. Forewing olive-brown, with or without isolated small light spots. Hindwing reddish and yellowish, with brownish black sublimbal spots.

C. archon *Burm.*, from Catamarca in Argentina, is compared with *C. therapon*, but is twice as large. *archon*. Colour greyish yellow suffused with brown, forewing with white fringes, brownish black median longitudinal band and hind border. Hindwing orange-yellow with narrow black marginal band, fringes as in *therapon*, in the middle a large black smear which is interrupted in the centre by six oval whitish spots forming a sinuous transverse band. Underside of wings and body lighter greyish yellow, both wings orange at the base, hindwing with indications of the markings of the upperside.

C. amalthaea *Druce*, from Brazil, has the forewing dark brown, bearing two white transverse bands *amalthaea*, shortened posteriorly. Hindwing orange with a black spot at the apex of the cell and a similar one between the latter and the inner margin; a sublimbal row of black spots having white pupils, and a black marginal line present. Fringes of both wings brown and the underside orange-red. Body above light brown beneath orange-red. Expanse 76 mm.

C. fonscolombe *Godt.* (= *japyx* *Hbn.*, *kirsteni* *Thon*, *walkeri* *Buchecker*) (5 b). Brazil. The ♀ differs from *fonscolombe*, the ♂ (5 b) in the presence of 5 small light spots on the forewing.

R. Hindwing with a magnificent blue sheen, and red marginal band. Forewing dull black, with light greyish band and small silvery glossy spots.

C. diva *Btlr.*, from Colombia and Central America, varies rather strongly. The red marginal band of *diva*, the hindwing, continuous in true *diva*, is sometimes separated into spots; form **maculifera** *form. nov.* (6 d, on the *maculifera*, plate as *diva*); — **tricolor** *Fldr.* (6 d) is a form with the markings particularly sharp. — A form from Chiriqui *tricolor*, is before me which has the band of the forewing much darkened (dark brown) and indistinct, and only one or two small silvery spots. This is **chiriquiensis** *form. nov.* The variability in size is also remarkable, there are *chiriquiensis*, before me ♂♂ of *chiriquiensis* from 55 to 90 mm (the type is 55 mm).

S. Hindwing black, usually with red spots; forewing with irregular white postmedian band from the anal angle about vertical to the costal margin, in the costal area on both sides of and parallel with it a white stripe. The insects resemble *Synemon*.

C. amycus *Stoll* (5 d), widely distributed in South America (according to KIRBY's Catalogue also in *amycus*, Central America), varies considerably. — **tristicula** *form. nov.* is a form of which I have as yet only seen *tristicula*, ♂♂; the red colour in the disc of the hindwing is obsolete and the red submarginal band on the same wing at most present in the dorsal area; from Blumenau, Espirito Santo, etc. — **alboinsignita** *form. nov.* *alboinsignita*, (5 d) has the transverse band of the forewing broad and pure white, a white submedian costal transverse spot in the forewing is at most indicated, the subapical costal transverse spot, however, is larger and the red markings on the hindwing are different.

C. meditrina *Hpfrr.* (5 d), from Brazil, on the whole has the hindwing more blackish than our figure *meditrina*, indicates.

T. Forewing greyish black with four whitish transverse bands; hindwing in the basal half white with black spot edged with red, in the apical half black with red and white markings.

C. juturna *Hpfrr.* (6 b), from Minas Geraes and Rio Grande do Sul; a rarer species. Our figure (6 b), *juturna*, which, like many others, is a copy from PREISS, is unfortunately not quite exact, in so far as there should be two more light postmedian transverse bands present in the forewing (as in HOPFER's figure), which are, however, not as distinct as the two present in our figure should be. PREISS's original type is before me; it is somewhat worn in the apical area of the forewing, but both the bands missing in the figure are distinctly recognisable. According to BURMEISTER (*Descr. Rép. Arg. Lép. Atlas*, p. 57) a form occurs in Paraguay which is somewhat smaller than the original figure and the black marginal band on the hindwing of which is interrupted by two rows of white red-edged spots parallel with the margin (**paraguayensis** *form. nov.*). *paraguayensis*.

U. Forewing similar to that of the preceding group, but only two light transverse bands present. Ground-colour of hindwing white or black, with white spots edged with red and black, margin always black.

C. endelechia *Druce* (6 c), from Paraguay, is easily distinguished by the white ground-colour of its hindwings from *endelechia*.

C. eudesmia *G. R. Gray* (8 e), as in this species the hindwing is black with a red postmedian band *eudesmia*, enclosing white spots and a sublimbal row of red spots each enclosing a white one. In the ♀ there is an orange-yellow discal spot. Chile. — Larva in the trunk of a Bromeliaceae, *Pourretia coarctata* (cf. PHILIPPI 1863, BUTLER 1882, CROWLEY 1894).

W. Wings black, forewing with grey oblique band, hindwing with white median band and with or without white sublimbal spots. Abdomen with red transverse bands.

C. garbei *Foetterle* (6 d), from Southern Brazil, strongly resembles *garbei*.

C. cochrus *F.* (8 c), likewise from Brazil (the habitat Chile in KIRBY's catalogue is erroneous); but in *cochrus*, the white band of the hindwing is much broader and situated before the middle of the wing, the light band of the forewing is not so distinct as in *garbei* and in the hindwing there are fewer (apparently at most 4)

maris, or no white sublimbal spots present. — *maris Dalm.* is said to have both wings of a deep black ground-colour bearing a rather sharply marked band on the forewing. *casmilus Hbn.* has only one white sublimbal spot in the hindwing, *bipunctata form. nov.* has two similar ones, *depunctata form. nov.* none at all; I have not seen a *depunctata* form *tripunctata form. nov.* with three such spots, but this doubtless occurs according to GODART's description. *tripunctata*. I consider the form with four sublimbal spots on the hindwing as typical. — *combinata form. nov.* (8 c) resembles *bipunctata*, but the white bands are narrower both above and below.

V. Forewing black with bluish and greenish sheen, without any markings other than a straight pale ochreous sharply marked transverse band running from the anal angle about vertically to the costal margin.

pelasgus. **C. pelasgus** *Stoll* (8 a) is one of the smaller species of *Castnia* (expanse of wings 43 to 58 mm.) and widely distributed in South America. Below, the light band is broader than above. — **unifasciata** *Fldr.*, from the Amazon, has the band of the forewing pure white.

X. Forewing blackish olive-violet with whitish Y-shaped band, hindwing red with black transverse band and black margin.

hecate. **C. hecate** *H.-Schäff.* (4 e) inhabits Hayti. Underside of forewing reddish yellow with blackish apex and the band of the upperside shining through.

Z. Forewing dark with broad and sharply marked transverse band which is elbowed in a right angle, being concave proximally, and three subapical vitreous spots. Hindwing black with two rows of red spots.

veraguana. **C. veraguana** Westw. (3 c ♀) occurs in Panama. In 1896 SCHAUUS described a ♂-form from Colombia under the provisional name of **C. govora** (8 d), the forewing only differing in that the subapical spots are more oblique, while the hindwing is velvety black with a row of large red marginal spots. Expanse 108 to 130 mm. I was enabled to examine a specimen of this form (from Bogota, Tring Museum) and believe that it is the ♂ of *veraguana*.

II. Gazera:

Forewing elongate-ovate.

(cf. Appendix pp. 16 to 17.)

A. Wing black with a light yellow spot in the hindwing.

mimica. **C. mimica** *Fldr.* (6 e) occurs at the Amazon, has red spots on body and at the base of the forewing and usually has a larger spot on the hindwing than our figure indicates.

B. Wings black with yellowish spots shining through.

linus. **C. linus** Cr., from Guiana, is represented in Brazil by the form **heliconioides** H.-Schöff. (7 c); true *heliconioides* differs from *heliconioides* in its lesser size, in the markings being paler yellow, the single spots of the lighter portion near the anal angle of the forewing shorter, the light submarginal spots of the hindwing, especially the two anterior ones, probably always shorter, and the two white dots in the anal angle present in *heliconioides* being absent in *linus*; the veins of the light discal area of this wing are not black and not darker than the ground-colour or only slightly so; the black transverse band of the underside on the hindwing is altogether broader than in *heliconioides*, and never separated into spots in the middle. — There is a form from Tarap in Peru before me which differs from *einus* in the following points: the light subapical band of the forewing is broadly ovate (9 × 14.5 mm.), the black band bounding it proximally is narrow, the subapical light area merges together with that in the anal angle, the light spot at the apex of the cell is rounded in a semicircle on the outside, in the anal angle of the hindwing two light dots are present, as in *heliconioides*. Expanse 80 mm (♂).

peruviana. I name this form **peruviana** form. nov. — There is a ♂ before me from Paraguay which probably belongs to *micha*. **micha** Druce, but it differs from the description in that the black band of the forewing is not very broad, the black transverse band of the forewing does not run into the anal angle any more than it does in the other forms of *linus*, but into the outer margin, the white submarginal spots of the forewing are three in number, and situated in the anterior half of the margin, the black transverse band of the hindwing is narrower than in *linus*, expanse 89 mm. The original description of *micha* reads as follows: "Primaries and secondaries hyaline, slightly irrorated with black scales; the veins all black; the costal, outer and inner margin edged with black; primaries very broad; a black band crosses the wing beyond the cell from the costal margin to the anal angle, and on the inner margin near the anal angle is a large round black spot; a black band crosses the cell about the middle; two white elongated spots about the middle of the outer margin. Secondaries crossed below the middle from the costal margin to the anal angle by a wide curved black band, the outer margin black. Head, antennae, abdomen, and legs black; sides of the abdomen greyish, with a white spot on the last three segments; thorax spotted with white. Expanse 4½ inches. Paraguay". — If the Paraguayan form before me should require a name, it might be called **michana** m.

linoides. **C. linoides** *spec. nov.* (8 b). The ♀ is similar to *linus*, but the markings of the forewing are narrower and white, the veins of both wings not scaled with black, the sublimbal spots of the hindwing white and much smaller than in *linus*, etc. — Paramba, 3500 ft., III, 1897, dry season (Type in Tring Museum).

dodona. **C. dodona** Druce. Forewing long, narrow, hyaline, with black veins apical band ovate and very broad, a black band straight across the middle of the cell. Hindwing with very small hyaline median area and a broad

black band from the costal margin to the anal angle; margin black with a few small white spots at the anal angle. Body black, antennae black with yellow tips, sides of abdomen light yellow. Expanse 121 mm. — Ecuador, Amazonas.

C. Smaller *Acraca*-like insect, with the ground-colour of both wings reddish, veins and marginal band of hindwing deep black; on the forewing a pale yellow subapical band.

C. acraeoides *G. R. Gray* (= *aetionophorus Koll.*) (8 a) occurs in Brazil, measures 60 to 70 mm in expanse *acraeoides*, and in the black marginal band of the hindwing bears a row of whitish dot-like spots which are bordered by the band at least posteriorly and laterally, while in *nervosa form. nov.* they are placed before the band, which is *nervosa*, only half as broad; this form, of which I have before me two ♀♀ specimens from São Paulo, both without abdomen, is moreover distinguished by the rather larger size (up to 74 mm.), the black veins more sharply marked, especially beneath, light ground-colour with a fairly distinct bluish green sheen. — GRÜNBERG described the metamorphosis in *Deutsche Entom. Zeits.*, 1909, pp. 127 to 130.

D. Forewing black, with yellow, red or brown markings, without a complete row of yellow submarginal spots, in the hindwing the afore-mentioned light colours usually predominate and the black forms the markings.

C. pellonia *Druce* (8 b), from the Upper Amazon, measures 85 mm in expanse, has the hindwing black, *pellonia*, with orange yellow markings only in the costal area, sometimes also with yellow submarginal spots; in the forewing the reddish yellow colour forms a transverse band not reaching the margin and enclosing a black round spot anteriorly, a narrow submedian band and a similar one at the inner margin. — *songata form. nov.* (8 b) *songata*, is distinguished especially by the absence of the black spot in the transverse band of the forewing. Rio Songo to Rio Suapi, Bolivia, 1100 m., in March (Tring Museum).

C. tarapotensis *Preiss* inhabits Eastern Peru; the black areas are dull, rather brownish, the light *tarapotensis*, ones greyish yellow in the forewing, forming an angulate band reaching from the base to the anal angle and two or three transverse bands in the costal area; on the hindwing an orange yellow straight band 6 or 7 mm. broad extends from the inner margin to the costal margin near the apex, and a row of light yellow angular submarginal spots is present.

C. melanolimbata *nom. nov.* (= *buckleyi Preiss nec Druce*) (8 a) is most easily distinguished from *melanolimbata*, *tarapotensis* by the underside of the forewing, which in the proximal two-thirds of its length is light-coloured, with the exception of a narrow band at the costal margin, a longitudinal streak and a transverse spot in the cell, as well as a large round spot outside the cell, which markings are black. — The form from Peru figured by PREISS as *buckleyi* differs from true *buckleyi*, described from Ecuador, in the absence of the light sublimbal spots in both wings, and in other respects also the markings of the two forms are not identical (cf. the original figure of *buckleyi* in *Proc. Zool. Soc. London*, 1882, t. 60, f. 3, with PREISS's plate V, fig. 2 and VII fig. 10). I have therefore given a new name to the species described by PREISS (having examined PREISS's type!).

C. ecuadoria *Ww.* (6 e) (= *ecuadorina* on our plate) is so well characterised by the markings of both *ecuadoria*, the thorax and the wings that it is not easily mistaken. — Ecuador.

C. simulans *Bsd.* (7 b), from Colombia, is distinguished i. a. by the straight and sharply marked *simulans*, transverse band of the apical half of the forewing.

C. personata *Wkr.*, from Guyaquil, has the forewing dark yellow with black markings; the apex is *personata*, broadly black, in the costal area a black, rather oblique, transverse spot which originates shortly before the middle of the forewing, from outside the middle of this margin an oblique band stretches to the centre and is followed by four more distinct yellow longitudinal spots. Hindwing in the middle lighter than the forewing, the costal margin, a median band and the distal margin black. The latter with four white spots. Expanse 36 mm. — According to WESTWOOD closely allied to *simulans*.

C. cononia *Westw.* (8 b), from Ecuador, is closely allied to *ecuadoria*, but the discocellular veins 8 and *cononia*, 9 are further apart. Moreover, the forewing has a postmedian transverse row of white spots, the red colour of these wings is separated into spots, and the black spots of the hindwing sharply are marked.

E. Like D, but on the forewing there is a row of yellow submarginal spots, occasionally confluent.

C. buckleyi *Druce*, from Ecuador, is similar to *melanolimbata*, but easily distinguished by the presence *buckleyi*, of light sublimbal spots in both wings (cf. species mentioned above). The hindwing only has a black shadow in the anal angle, and the black spot at the apex of the cell of the forewing is much smaller than in *melanolimbata*.

C. mars *Druce*, from Ecuador, occurs at the Upper Amazon (Pebas) in a form figured by PREISS (whose *mars*, excellent figure we reproduce here) under the name of *mars*, which is distinct from true *mars*, and which I name *amazonica* (7 b). True *mars* differs from this *amazonica* in the black median oblique band of the hindwing being shorter and narrower and consequently much narrower than the red patch lying on its inner side; the black marginal band of the hindwing also is narrower, the black submedian costal transverse band of the forewing is shorter and the black longitudinal bands of this wing narrower than in *amazonica*. *amazonica*.

C. melessus *Druce* (7 a), from the Upper Amazon, is distinguished i. a. by the large, sometimes confluent *melessus*, sublimbal spots of the forewing *).

*) This figure also, like many others, is taken from PREISS's work on Castniidae, the figures of which, some of them coloured, are excellent reproductions.

- zagraea*. **C. zagraea** *Fldr.* (7 c) occurs in Panama. The four specimens of this species before me like their figure in *Biolog. Central.-Amer.* do not show the lighter colour at the margin of the forewing present in our figure.
- carilla*. **C. carilla** *Schaus.* Antenna yellow with black base. Thorax dark brown with yellow spots. Abdomen reddish with a sublateral black stripe, whitish yellow beneath. Forewing black, basal half of the cell and a broad longitudinal band in the dorsal area reddish brown, a spot at the apex of the cell and a streak opposite at the costal margin yellow, a postmedian rectangular brown spot traversed by vein 3, a subterminal oblique row of yellow spots, a row of yellowish white marginal spots. Hindwing reddish with broad black subcostal band, black marginal band deeply dentate on the inner side and a postmedian black band between veins 2 and 4. Expanse 96 mm. Allied to *C. zagraea*, but the basal brown markings are quite different. — Costa Rica.
- columbina*. **C. columbina** *Bsd.*, from Colombia, measures 120 mm. in expanse and has the forewing black with two red longitudinal bands from the base, the lower one of which ends in two whitish smears, moreover about four white spots are present and towards the apex there are two parallel rows of white spots. Hindwing reddish yellow with black marginal band, and white row of spots as well as 2 or 3 isolated black spots.
- cycna*. **C. cycna** *Westw.* (7 d, on the plate misprinted as *cygna*) from Colombia, sometimes occurs in a form (type ♂ from Bogota) in which the light spot situated behind the transverse spot at the apex of the cell of the forewing merges into the postmedian row of spots, while these spots are confluent, forming a continuous band (f. **modificata** *form. nov.*) (cf. plate VI, fig. 7 in PREISS, *Neue Arten Castnia*).
- modificata*. **C. modificata** *form. nov.* (cf. plate VI, fig. 7 in PREISS, *Neue Arten Castnia*).
- daguana*. **C. daguana** *Preiss*, from W. Colombia, strongly resembles *zagraea*, but is smaller (expanse 68 mm.), while a yellow longitudinal patch is present also in the cell of the forewing, the submarginal spots of the forewing are smaller, those of the hindwing are not pointed at the distal end.
- hahneli*. **C. hahneli** *Preiss*, from Venezuela, is also very like *zagraea*, but considerably smaller (expanse 61 mm), colour paler, position and shape of spots at the hindmargin on the underside of the forewing different, the postmedian light transverse markings of the same wing appear as a continuous band instead of a row of spots, etc.
- michaeli*. **C. michaeli** *Preiss* (6 e), from the Upper Amazon, is characterised i. a. by the markings of the proximal half of the forewing.
- juanita*. **C. juanita** *Preiss*, from N.-W. Colombia, is one of the largest species of *Gazera* (length of wing 53, expanse about 105 mm.), the only specimen before me, the type, is defective, and has orange-red hindwing, bearing a deep black marginal band about 14 mm. broad and sharply marked on its inner edge, enclosing a few small yellow submarginal spots. In the forewing a similar marginal band is present, otherwise the forewing is light yellow with two or three black longitudinal bands and two black spots.
- garleppi*. **C. garleppi** *Preiss*, from Bolivia, measures 90 mm in expanse and resembles *zagraea*, the black sublimbal spots of the hindwing are, however, distant from each other and quite isolated, and the black marginal band has quite short teeth on its inner side, the sublimbal spots of the forewing are smaller, and the row is broadly interrupted in the middle. A postmedian transverse row of spots is only indicated by a small light smear, etc.
- salvina*. **C. salvina** *Westw.* (7 e), from Panama, occupies a rather isolated position in this group by the widely extended deep black colour of the forewing and the markings consisting of single white spots.
- cratina*. **C. cratina** *Westw.* (7 d), from the Amazon, also differs from the type predominant in this group, i. a. in the light veins of the forewing.
- F. Hindwing uniformly black. Forewing black with yellow transverse marking in the centre.
- truxilla*. **C. truxilla** *Westw.* (7 b), from Colombia, looks rather strange on account of the almost entire absence of the spots otherwise so strongly prominent among *Gazera*.

Addenda.

Species which could not be included in the two preceding divisions of the genus *Castnia* (cf. p. 7).

- hechtiae*. **C. hechtiae** *Dyar* (8 a), from Mexico, is gray, forewing with black shadows and a white band running from near the base along the median vein to the base of vein 2, then filling out the space between 2 and 3, afterwards extending obliquely costad close to the cell, ending at vein 7. Hindwing orange red with strongly curved black band at the apex of the cell, a submarginal band of black spots and narrow black marginal band. ♂ expanse 65 mm. — This species, with which I have only lately become acquainted, should form a separate group among the true *Castnias*.

C. marcus Jord. (8 c). ♀: Body green, with bluish and ochreous red tints. Forewing metallic dark green, in the centre of the costal area a large irregular creamy yellow spot. Hindwing ochreous red, but so strongly shaded with purplish black that the ground-colour is only distinct at the anal angle and in a small area in the cell; the wing has a blue or green sheen in certain lights. Expanse 42 mm. — Pebas. *marcus.*

C. gramivora Schaus. Body above light brown, below whitish. Forewing light brown, partly olivaceous, in the distal half a large semitransparent area, which does not extend to the margins, is transected by brown veins and anteriorly interrupted by a large brown spot, which extends from the costal margin. Hindwing brown, reddish at the base, with reddish brown marginal spots and a large semitransparent submarginal area. The wings are much paler beneath. Expanse 64 mm. São Paulo, Brazil. — The form of the ♀ figured on pl. 8, **parana** form. nov. (8 d), is presumably not specifically distinct from *gramivora*, but is smaller (45 mm), the semidiaphanous area of the forewing is centrally not interrupted by a brown spot, the cell of the forewing bears a semitransparent spot, and both wings have a narrow brown marginal band. Castro, Paraná, in the Tring Museum. *gramivora.* *parana.*

C. corrupta Schaus. Dark brown, appearing dark metallic green in certain lights, anus orange-red. At the anal angle of the hindwing a red spot, and between this spot and the centre of the wing creamy white scales. On the underside the wings are dusted with reddish scales, which form an indistinct band on the forewing and two more distinct ones on the hindwing. Expanse 110 mm. — Colombia. *corrupta.*

C. angusta Druce. ♂: Body dark brown, legs black-brown. Forewing dark brown, bluish at the base and distally on the veins; at the apex of the cell a light yellow spot, beyond which there is a narrow yellow transverse line running from the costal margin to the hind angle; fringes yellow. Hindwing with the ground as on forewing; beyond the centre a transverse row of narrow, yellow, luniform spots from near the apex to the anal angle, and near the margin a row of 6 round yellow spots, fringes also yellow. Underside lighter brown, on the forewing the yellow band much broader than above, and there is a sublimbal row of 3 yellow spots; hindwing with two rows of yellow spots. Expanse 165 mm. — Ecuador. *angusta.*

C. laura Druce, from Chapada in Brazil, has the forewing brown with a broad white band from the centre of the costal margin to the hind angle, narrowing posteriorly; near the apex 6 round white spots, of which the three anterior ones form a straight row, while the three posterior ones are placed in a slightly curved row; fringes brown and white; underside like upper, but the white markings more sharply defined, there being moreover a row of large orange-yellow marginal spots. Hindwing brown, with a row of large, pure white spots from the costal margin almost to the anal angle, and large orange-yellow marginal spots; underside like upper, but lighter; fringes brown. Body and legs dark brown, anus orange. Expanse about 102 mm. *laura.*

C. dolopia Druce. ♀: Abdomen black, brown at the base like the rest of the body; antenna black with light brown apex. Forewing dark brown, with large greyish brown spot at the apex of the cell, beyond the latter a transverse row of greyish brown spots edged with black, at the hindmargin two black luniform spots. Hindwing black, with a row of brownish white spots from near the anal angle almost to the apex; fringes brownish white. Underside of both wings light brown, all the spots much more distinct and edged with black. Expanse 197 mm. — Ecuador. *dolopia.*

C. delecta Schaus. ♂: Thorax whitish grey, venter orange-yellow, the body otherwise brown. Forewing reddish brown, with large (dark brown?) spot at the apex of the cell, a dark brown line from the centre of the hind margin to the apex, a subapical white spot, and dark brown fringes. Hindwing reddish, black posteriorly at the base, distally with 5—6 darker spots and a brown marginal band from the anal angle to vein 6. Expanse 49 mm. In the ♀ the forewing yellow, partly darker, with two white subapical spots, basal area reddish brown. Hindwing reddish yellow, with orange veins, and smaller spots. Expanse 57 mm. — Costa Rica, Mexico. *delecta.*

C. wagneri Buchecker, from Colombia, is unfortunately not known to me, nor have I seen a description. *wagneri.*

The two following species form a group by themselves, being characterised, *inter alia*, by the small size and the magnificent colouring (at least in *erycina*); they are both unknown to me in nature.

C. erycina Westw. (= *hyperbius* Westw. in tab.), from Ecuador, is (together with the next species) an isolated form recalling Erycinidae, from which it has derived its name. The size (expanse 40 mm) is quite exceptionally small among the *Castniae*; the forewing is blue at the base for a distance of 5 mm, then follows a red transverse band, slightly narrower, the rest of the wing being glittering green; the ground appears to be dark everywhere. Hindwing blue-black from the base to two-thirds, glossy silvery green in the distal area, and blood-red at the costal margin.

C. pelopia Druce, from the interior of Colombia, is said to be nearly allied to *erycina*, but is much more black, the underside of both wings is grey-green, and the venter light red, while in *erycina* it bears green bands. *pelopia.*

2. Family: Zygaenidæ.

This family, for the description of which we refer the reader to Vol. 2 (p. 3; 4) and Vol. X (p. 5), is very poorly represented in America. The forms which occur there are all small and in general appearance as well as in colouring resemble species of other families, especially Lithosias and Micros, so that it is only recently that they have been recognised as belonging to the Zygaenids. They were formerly treated as a distinct family under the name of *Pyromorphidae*, but there is nothing in their structure to justify a separation from the *Zygaenidae*. The head is similar in build to that of the *Zygaenidae* of the Old World, the legs and antennae agree with those of many of the Old World species of this family, the claws are toothless as in the latter, and the submedian vein (vein 1 c) is well developed in both wings.

With the exception of a few species found in the United States, the American Zygaenids are very rarely met with. They are very poorly represented in collections, and their study is consequently very difficult, especially as many of the species are uniform in colour and variable in venation. The classification here adopted must therefore be regarded as merely a temporary one. The number of the species actually existing is evidently very much larger than the number of those as yet known.

The moths are sluggish and in daytime rest on leaves, twigs and low herbage, or suck at damp stones in brooks.

The early stages are only known of a few North American forms; practically no observations have been recorded of the larvae, pupae, food-plants and habits of the moths of Central and South America. All that we know of these species are a few specimens in museums, which, moreover, are generally in a bad state of preservation.

The American Zygaenids all have the tongue well developed and the palpi short. The spurs of the middle and hindtibiae are always very short, and the hindtibia has always only one pair. The spur of the foretibia (epiphysis) is usually present. The absence or presence of this spur is of no great importance, as quite closely allied species differ in this respect. Our division of the Old World *Zygaenidae* into *Zygaeninae* with epiphysis, and *Chalcosiinae* without it, therefore cannot be strictly applied to the American forms. But I believe the American species without epiphysis to be *Zygaeninae* which have secondarily lost this spur.

A. Hindwing with 8 veins.

1. Genus: **Euclimacia** gen. nov.

Antenna of ♂ with short pectinations, of ♀ dentate. Foretibia with spur. Spurs of middle and hindtibiae exceedingly short. Venation differing from that of all other Zygaenids. In the forewing 13 veins (instead of 12), 11 of which branch off from the cell, costal vein very short, the first four branches almost vertical to the costal margin, cell very long, extending beyond $\frac{3}{4}$ of the length of the wing, the first subcostal branch originating at $\frac{2}{5}$ of the cell, the lower median branch being opposite the 4th subcostal branch. In the hindwing the costal vein confluent with the subcostal vein almost to the apex of the cell, the middle and lower radials close together from the lower angle of the cell, the lower median branching off at $\frac{3}{5}$.

One species.

E. tortricalis Druce (9 a). Bluish black; head and thorax with light stripes; abdomen above ringed *tortricalis*. with orange. Wings reddish orange, costal and outer margins of forewing black with pale yellow streaks between the veins, in the hindwing a longitudinal stripe and a band of elongate marginal spots blue-black. — Costa Rica, one pair in the British Museum.

2. Genus: **Malthaca** Clem. (= *Pyromorpha* H.-Schäff. indescr.)

Antennae bipectinate or dentate. Venation complete in both wings, in forewing 12, in hindwing 8 veins. Anterior and posterior angles of the cell of hindwing at the same level or the posterior angle produced. — The fairly numerous species here united have hitherto been placed in a number of genera, which were thought to differ particularly in outline and in some details of venation.

The only character in venation which is apparently fairly constant, and divides the species into two groups, lies in the connection of the costal vein with the cell of the hindwing.

- a) The costal vein of the hindwing is to the greater extent confluent with the cell and the oblique vein which connects the costal vein (vein 8) with the free subcostal branch (vein 7) is short. — Here belong *dimidiata* (genotype of *Malthaca* Clem. = *Pyromorpha* H.-Schäff. indescr. et partim).

radialis (genotype of *Gingla Wkr.*), *josalis*, *aequalis*, *marginata*, *thyesta*, *fusca*, *martenii* and some of the nov. spec.

- b) The costal vein of the hindwing is united to the cell to a lesser extent, and the oblique vein between the costal and the subcostal branch is long. — Here belong *centralis*, *mexicana*, *timon* (genotype of *Coementa Druce*), *correbioides* (genotype of *Felderia Kirby*), *rata* and *morio*.

For the purpose of the present work, however, it is advisable to arrange the species according to colour.

- a) Forewing at least partly yellow or red.

dimidiata. **M. dimidiata** *H.-Schäff.* (= *perlucidula Clem.*) (9 a). Black, slightly purplish blue, foreleg partly yellowish, wings semitransparent, in the ♂ much more broadly and strongly rounded than in the ♀, with a yellow patch extending from the base to about the middle of the costal margin and from there to the upper submedian vein, but sometimes reduced to a narrow costal stripe. Subcostal branches 3 and 4 of the forewing stalked. Early stages described by DYAR in "Psyche" (1897, p. 128). The larva lives singly in oak-woods beneath the fallen leaves, on which it feeds; when full-grown dark velvety brown with brown warts, the upper three of which are placed in large, rather oblique, pale grey patches. Cocoon brownish, sparsely covered with loose white silk. Hibernates as pupa. — Atlantic States and northern Mexico.

centralis. **M. centralis** *Wkr.* (= *notha Edw.*) (9 a). Black, slightly purplish, the bases of both wings, the sides of the pronotum, a frontal spot and a spot behind the eye, as well as the greater part of the palpi yellow. In both wings the two median branches far apart, in the forewing subcostals 3 and 4 stalked or from the cell. — Arizona and Mexico.

mexicana. **M. mexicana** *Druce* (9 a). Black, patagia anteriorly and prothorax laterally orange-yellow, as are also a frontal spot, the palpi, a spot on the forecoxa, some scales on the foretibia, the greater part of the forewing and the costal margin of the hindwing. — Mexico.

correbioides. **M. correbioides** *Fldr.* (9 a). Like the preceding species, but red instead of yellow, all coxae red at least laterally, frontal spot large. As in *mexicana* the costal vein of the hindwing anastomoses with the cell only for a short distance. — Mexico: Cuernavaca; 1 ♂.

erythromelas. **M. erythromelas** *spec. nov.* (9 a). Purplish black, foreleg with reddish stripe. Wings like *M. centralis* in outline; forewing vermilion, a very narrow costal margin, a broader border to the hind and outer margins the last extending almost to the lower angle of the cell purple-black and somewhat irregular on its inner edge, base also purplish black, veins free or subcostal veins 3 and 4 from the same point, upper median branch near the angle of the cell. Hindwing purple-black, with broad vermilion costal stripe, which extends to below the cell and is obtusely pointed towards the apex; upper angle of cell transversely truncate, between subcostal and first radial the oblique vein connecting the angle with the costal vein longer than half the breadth of the cell, first median branch twice as far from the second median as from the first radial. Length of forewing 12 mm. — 1 ♂ in the Oxford Museum (coll. Westwood) from Mexico.

aequalis. **M. aequalis** *Druce* (9 a). Less deeply red than *correbioides*, the black margin narrower, the hindwing quite black without red costal stripe, vein connecting costal and subcostal veins of hindwing short, oblique. In the forewing subcostals 4 and 5 stalked. — Mexico: Coatepec.

marginata. **M. marginata** *Edw.* (9 b). Body black, thorax orange, wings dull orange, with very narrow black margin, which on the forewing is produced along the costal margin to the middle. — Mexico: Vera Cruz.

teos. **M. teos** *Schaus* (9 b). Body black, collar orange. Forewing light brown, at the costal margin yellowish to $\frac{2}{3}$ of its length, hindwing dull orange, the outer margin of both wings narrowly black as in the preceding. Underside dull orange with black outer margin. — Mexico: Vera Cruz. Not known to me. The figure in Biol. Centr.-Amer. which we reproduce here seems to be inexact (as also that of *marginata*).

rata. **M. rata** *Edw.* (9 b). Pale yellow, upperside of head, the antenna, meso- and metanota and upperside of abdomen as well as the outer margin of both wings purplish black, the marginal band somewhat diffuse, especially on the underside of the hindwing, costal margin of forewing very narrowly black to the base. On the forewing subcostals 3 and 4 stalked, in the hindwing the costal vein anastomosing with the cell for a short distance. — Arizona.

radialis. **M. radialis** *Wkr.* (9 b). Body black striped with yellow, underside with grey bands. Wings yellow with black outer margin; in the marginal band of the forewing between the veins nine pale yellow streaks and in the subcostal fork a pale yellow dot; connecting vein between costal and subcostal veins of hindwing perpendicular to the costal, not oblique, lower angle of the cell strongly produced. In the forewing subcostals 4 and 5 stalked. — Mexico: Vera Cruz.

drucei. **M. drucei** *spec. nov.* (= *radialis Druce nec Wkr.*) (9 b). The legs less extended yellowish grey than in *radialis*, forewing with broad black stripe along the hindmargin, which in *radialis* is only indicated by a few scales, in the marginal band 11 pale yellow streaks, marginal band of hindwing broader anteriorly and posteriorly than in *radialis*; connecting vein between costal and subcostal veins of hindwing directed

obliquely basad, the hind angle of the cell less strongly produced than in *radialis*. — Guatemala.

M. josialis Druce (9 b). Head and sides of thorax and abdomen yellow. Wings black, costal and hind margins of both wings yellow, in the hindmarginal streak of the forewing an abbreviated blue-black streak. In the forewing subcostals 4 and 5 stalked; connecting vein between costal and subcostal of hindwing oblique. — Guatemala.

b) Forewing uniformly dark without yellow or red.

M. timon Druce (9 b). Blue-black; hindwing carmine with narrow black marginal band. Veins of forewing from the cell, costal vein of hindwing anastomosing with the cell for a short distance. — Costa Rica.

M. morio Druce (9 c). Blue-black, abdomen red laterally, hindwing blue. Venation as in *timon*. — Guatemala and Costa Rica.

M. xanthura spec. nov. (9 c). ♀: Uniformly glossy blue, upperside of hindwing, the abdomen and the entire underside tinged with green; the last 2 (above) or 3 (below) abdominal segments orange, with slight purple sheen. Tongue dirty yellowish brown. Antenna pointed, bipectinate, the middle teeth about 4 or 5 times as long as they are broad, all scaled. Spur of foretibia distinct. Veins of forewing from the cell (left wing) or subcostals 4 or 5 stalked (right wing); in the hindwing the costal anastomosing with the cell for a long distance, connecting vein between costal and subcostal oblique and short; in both wings the lower median far proximal and in the hindwing the upper median about in the middle between the lower median and the third radial (as in *timon* and *morio*). Length of forewing 15 mm. — 1 ♀ from Ecuador, without any more exact locality (obtained from Herr NEUBURGER, Berlin) in the Tring Museum.

M. fusca Edw. (= *landia* Druce) (9 c). Body yellow, upperside of head and abdomen blackish, underside of abdomen with broad black stripe, legs to the greater extent dirty yellowish brown. Antennae blue-black. Forewing semitransparent, uniformly brownish black, in oblique aspect with blue sheen, scales very narrow, almost like hair. In the forewing the veins from the cell, but subcostals 3 and 4 usually from one point (probably sometimes stalked), in the hindwing the connecting vein between the costal and subcostal short, oblique. — Arizona, and Sonora in Mexico.

M. martenii French (= *barnea* Druce) (9 c). Black, faintly metallic, in the ♂ the inner side of the forecoxa and forefemur yellowish. Wings semitransparent, scales hair-shaped, denser in the ♀ than in the ♂. Venation as in *fusca*. — Arizona, New Mexico, Sonora in Mexico.

M. thyesta Druce (9 c). Similar to the preceding species, but the anterior portion of the thorax and the occiput yellow. Subcostal 2 of the forewing sometimes absent. — Guatemala.

3. Genus: **Gonioprocris** gen. nov.

Like *Malthaca*, but the upper angle of the cell of the hindwing much further produced than the lower angle, connecting vein between costal and subcostal long, radials 1 and 2 of hindwing from the point of the upper angle, but separate, cell between radials 2 and 3 deeply angulate, the upper arm of the angle longer than the lower one. In the forewing the veins from the cell. — Genotype: *G. xena* spec. nov.

G. xena spec. nov. ♂: Brownish black, with slight purple sheen, thorax above slightly yellowish, underside of head, thorax and abdomen pale yellow, likewise the larger portion of the underside of the legs. Frons broader than one eye (in a frontal view). Antenna with long pectinations, serrate at the tip. Forewing semitransparent, hairy, narrow, yellowish grey to the apex of the cell, the veins and a cell-spot blackish, outer area also blackish, in every cellule two yellowish grey stripes which unite forming an ellipse, a diffuse black discocellular band without yellowish grey scales, cell stalked, median and subcostal veins touching. Hindwing vitreous, very sparsely hairy, fringes black with yellowish grey spot below the 2nd median vein, a yellowish grey postmedian spot below the submedian 2. — 1 ♂ in the British Museum, from the Volcans de Agua, Guatemala, 8500 to 10500 feet (CHAMPION).

G. megalops Druce (9 c). ♂: Frons narrow, eyes large. Body black with a green gloss. Wings green, semitransparent. — Guatemala.

4. Genus: **Pseudoprocris** Druce.

Like *Malthaca*, but the antennae simple, incrassate distally much as in *Zygaena*, densely scaled with the exception of the underside of the club. Veins of forewing from the cell; in the hindwing the connecting vein between the costal and subcostal long.

P. gracilis Druce (9 d). Body, antenna and legs glossy bluish green. Forewing dull bluish green; hindwing transparent with dark edges; below both wings with blue-green gloss, which is stronger on the hindwing than on the forewing. — Mexico: Vera Cruz.

dolosa. **P. dolosa** Druce (9 d). Head and thorax (abdomen missing) as well as antenna and legs black, without distinct blue gloss; forewing semitransparent, blackish with dark edges; hindwing transparent with blackish apex and costal margin; on the underside the costal margin of the hindwing densely clothed with green scales. — Guatemala, only 1 ♀ known.

5. Genus: **Tetraclonia** gen. nov.

Forewing with only 11 veins, as one of the subcostal branches is absent, in the hindwing 8 veins. Very closely allied to *Malthaca*. — Genotype: *T. saucia* spec. nov.

- dyraspes.* **T. dyraspes** Druce (9 d). Very like *Acoloithus falsarius*, rather larger. Black, wings semitransparent, the hairs on the hindwing particularly sparse. Collar yellow, black in the middle. A small species. Connecting vein between costal and subcostal of the hindwing short and very oblique. — Mexico: Guerrero.
- cinniana.* **T. cinniana** Druce (9 d). Body black, thorax anteriorly pale yellow, forewing brownish black, a narrow costal stripe, abbreviated distally, and the hindwing pale yellow, hindwing with broad blackish marginal band. Venation as before. — Guatemala.
- ripena.* **T. ripena** Druce (9 d). Black, frons greyish yellow, collar red, abdomen and wings purple-brown. Forewing semitransparent distally between the dark vein-stripes. Hindwing red, with black outer margin. Forewing beneath with red longitudinal smear in the basal half. Veins of forewing from the cell; connecting vein between costal and subcostal of hindwing very short. — Bolivia.
- latercula.* **T. latercula** Edw. Similar in colour to *Malthaca aequalis* and *correbioides*. Forewing red with broad black marginal band, which is continued at the hind margin as a thin streak and also extends for a short distance along the costal margin. Hindwing with red costal margin. — Arizona.
- dyari.* **T. dyari** nom. nov. (= *laterculae* Dyar). Not known to me in nature. According to DYAR the forewing has 11 veins. Forewing red with narrow black margin which at the costal and hind margins is produced basad as a short thin streak. Costal margin of hindwing rather broadly red. — Arizona.
- forreri.* **T. forreri** Druce (9 d). Uniformly black, wings semitransparent. Connecting vein between costal and subcostal of hindwing long. — Mexico: Milpas. In one specimen subcostal 4 is forked, so that 12 veins are present.
- metallica.* **T. metallica** Schaus. Only known to me from the figure; perhaps belongs to *Malthaca*. Head and thorax black, abdomen dark green. Forewing above greenish black, hindwing metallic blue; underside of both wings metallic blue-green. Expanse 30 mm. — Peru.
- saucia.* **T. saucia** spec. nov. (9 d). ♀: Black, everywhere with a fairly strong blue sheen, upperside of forewing somewhat greenish. Forecoxa with a small red lateral spot. Forewing slightly transparent, the scales being very narrow, and the veins darker than the ground. The connecting vein between the costal and subcostal of hindwing short. Antenna pointed, bipectinate, distally dentate, the branches short and pointed, those of the central segments only being about half as long as the diameter of the shaft. Length of forewing 14 mm. — Cushi, Peru (type), and Yungas de Coroico, Bolivia, two ♀♀ in the Tring Museum.

6. Genus: **Chilioproceris** gen. nov.

As in *Malthaca* both wings with venation complete (forewing 12, hindwing 8 veins), but in the forewing subcostal 1 much more proximal than the lower median, while in *Malthaca* these branches originate from the cell at about the same level; none of the veins of the forewing stalked, in the hindwing the costal anastomosing with the cell for a shorter or longer distance, the connecting vein between the costal and subcostal long, apex of the cell deeply angulate, upper and lower angles truncate, projecting about equally far. Antenna of ♂ bipectinate, that of the ♀ simple, slightly flattened beneath. — Genotype: *Ch. melas* Guér. (1839).

Most easily distinguished from *Proceris* and *Pollanisus* by the presence of a strong foretibial spur.

melas. **Ch. melas** Guér. (9 d). Brownish black, antenna blue, body and upper side of forewing dull dark green without gloss, tongue orange-red. On the underside the hindwing and the apex of the forewing faintly but distinctly purple-blue. — Chile.

B. Hindwing with 7 veins (as the 2nd radial = vein 6 is absent).

7. Genus: **Triplocris** Grote.

Frons broad, produced in ring-shape and the frontal surface of this broad swelling somewhat raised

in cone-shape. Forewing with 11 veins, all free, or subcostals 2 and 3 stalked; in the hindwing the connecting vein between the costal and subcostal short. Foretibia with spur and apical thorn.

T. smithsonianus Clem. (9 e). Black, with slight greenish blue gloss; forewing dull dark bluish green, hindwing more blue, both wings slightly transparent, with blue fringes. Tongue quite small, yellowish white; legs short. Length of forewing 6 to 9 mm. — New Mexico, Colorado, Arizona. — Larva described in detail by DYAR in Proc. Ent. Soc. Wash. 5, p. 33 (1902). When fullgrown, with broad black dorsal stripe edged with white, below which is a pale red line, further down a white-edged black line, a pale red one and a black stripe with a broad white lower edge, and a black subventral line. Cocoon opaque, white, in the ground or among leaves. Food-plant: *Allionia nyctaginea*.

T. yampai Barn. Not known to me in nature. Appears to resemble *Seryda cincta* in colouring. According to kind communication from Dr. McDUNNOUGH the frons is similar to that of *smithsonianus*, but not quite so strongly produced. In the forewing 11 veins (not 12 as in *Seryda*), the two middle subcostal branches (2 and 4, 3 absent) from a point or on a short stalk. Black, collar on the upperside and the abdomen (with the exception of the tip and a broad ventral stripe) red. — Arizona.

8. Genus: **Acoloithus** Clem.

Frons slightly convex, not produced as in the preceding species. Tongue well developed. Forewing with 11 veins, all free, or subcostal 4 and radial 1, or radial 3 and median 1, on a very short stalk, in the hindwing 7 veins, connecting vein of costal and subcostal long.

A. falsarius Clem. (= *ruficollis* Druce) (9 e). Black, with purplish blue sheen. Collar orange-red, interrupted in the middle. Wings brownish black, forewing dull purple-blue, hindwing semitransparent. Tongue pale yellow. Length of forewing 6 to 7 mm. — Atlantic States of the U. S. A. southward to Mexico. — Larva on vine, sometimes injurious, when fullgrown 8 or 9 mm in length. Pale olive, green or reddish, with 5 interrupted longitudinal lines, the upper two warts dark, the third pale with the exception of segment 6. Hibernates as pupa.

A. novarius Barn. and McDun. Like the preceding, but the collar uniformly yellow, not interrupted, and complete also on the underside. Head and legs paler than in *falsarius*, eyes much larger, frons correspondingly narrower, evenly convex and distinctly narrowed anteriorly. — Texas.

A. rectarius Dyar (9 e). Entirely greenish black, cross-veins of the hindwing oblique and not angulate in the only specimen before me — Arizona.

A. opacus spec. nov. (9 e). ♀: Body dull blackish green. Antenna slightly incrassate distally, pectinations short, the longest scarcely as long as the diameter of the shaft. Foretibia with spur. Forewing above dull purplish black, hindwing greenish blue, almost without gloss, underside of both wings faintly purplish. In the forewing all veins free, median 1 near the angle of the cell, median 2 far proximal, in the hindwing the upper and lower angles of the cell at the same level, as the apical (concave) angle of the cell is equilateral. Length of forewing 9 mm. — 1 ♀ from the Rio Aguaca Valley, West Colombia, collected by A. H. FASSL at an altitude of about 2000 m.

A. isochrous spec. nov. (= *pusilla* Druce, nec Wkr., err. determ.). Body, underside of both wings, upperside of forewing and part of the tibiae metallic green, abdomen with coppery sheen, especially beneath. Upperside of hindwing purplish black. Underside of both wings opalescent. In the forewing radial 3 and median 1 on a short stalk. Tongue very pale yellow. — 1 ♂ from the Volcano de Chiriqui, in the British Museum.

A. basalis Edw. (9 e). A large species. Blue-green, slightly glossy, hindwing purplish black, with large grey patch extending from near the base to beyond the apex of the cell and bounded anteriorly by the cell-fold. Veins free. — Mexico: Vera Cruz.

A. flora Schaus (9 e). Similar to *basalis*, wings more triangular with the apex more pointed. The yellowish white area of the hindwing smaller, with broad glossy blue edge, especially at the abdominal side. — Costa Rica.

A. viridis Druce (9 e). Also a large species. Veins free, connecting vein between costal and subcostal of hindwing shorter than in the preceding species, about half as long as the cell is broad; in the right forewing 11 and in the left 12 veins! Upperside of body dull green, wings dull purplish green. Antenna and underside of wing and body green and very strongly glossy. — Southern Brazil: Casa Branca.

9. Genus: **Pycnoctena** Fldr.

Forewing with 12 veins, all free; hindwing with 7, connecting vein between costal and subcostal short, very oblique, upper angle of cell much more produced than the lower. Foretibia without spur (♀), the spurs of mid- and hindtibiae fairly long. Antenna stout, densely bipectinate (♀).

angustula.

P. angustula *Fldr.* (9 e). Upperside of head and thorax, antenna and apex of abdomen blackish blue, underside of thorax and the abdomen red. Forewing narrow, dirty yellow, with purple gloss, a diffuse large spot in the distal area of the cell and the margins black. Basal half of the hindwing reddish yellow, distal area vitreous with the exception of the yellowish grey costal margin, fringes brownish black. Length of forewing 10 mm. — 1 ♀ (type) from the Amazon, in the Tring Museum.

10. Genus: **Seryda** *Wkr.*

Forewing with 12 veins, all free; hindwing with the connecting vein of costal and subcostal about as long as half the diameter of the cell, or shorter, upper angle of the cell less produced than the lower, or both at the same level. Foretibia with spur.

cincta.

S. cincta *Wkr.* ♀: Dull blue-black; antenna with faint blue-green gloss, the pectinations stout, the middle ones about three times as long as the diameter of the shaft. Segments 1 to 4 of abdomen entirely red. Wings narrow, forewing above dull blue-black, hindwing and underside of both wings blackish brown, with faint blue sheen. Apex of cell of hindwing deeply angulate. Length of forewing 8½ mm. — 1 ♀ (type) from the Amazon, in the Oxford Museum.

isa.

S. isa *spec. nov.* (9 e). ♂: Like *cincta*, but the abdomen red only laterally on segments 1 to 3. Branches of antenna very thin, long, filiform, slightly incrassate towards the apex, far apart, the central ones about 6 times as long as the diameter of the shaft. Apex of cell of hindwing deeply angled. — 1 ♂ from Guayaquil, West Ecuador; the forewing very much worn.

actinota.

S. actinota *spec. nov.* (9 f). ♀: Body uniformly greenish blue. Antenna blue, distinctly incrassate distally, then pointed, the pectinations longest between the middle and apex, where they are ¼ as long again as the diameter of the shaft. Wings semitransparent, with very distinct dark veins, wings bluish green, elongate, elliptical, without hind angle. Hindwing and underside of both wings blue. Tongue dark. Length of forewing 11½ mm. — 1 ♀ from the Rio Aguaca Valley, West Colombia, found by A. H. FASSL at an altitude of about 2000 m.

thyana.

S. thyana *Druce* (9 f). Body greenish black; tongue pale yellow. Wings semitransparent, black with faint dark edges, scales of underside hair-shaped. Teeth of antenna of ♂ long and thin. — Guatemala.

glaucotis.

S. glaucotis *Hmps.* (= *mystica*, *Druce*, nec *Wkr.*, err. determ.) (9 f). Smaller than *thyana*, tongue blackish, pectinations of antenna of ♂ at most four times as long as they are broad. Otherwise like *thyana*. — Guatemala, 1 ♂ in the British Museum.

anacreon.

S. anacreon *Druce* (9 f). Broad-winged. Black, a spot between the antennae, a larger one at each side of the occiput, the collar (slightly interrupted in the middle) and the patagia, a median stripe on the mesonotum yellow, as is also the forewing, hindwing orange. Distal margin of forewing and apex of hindwing very narrowly black, forewing likewise with faint black smear at the distal margin near the base. — Costa Rica, and Chiriqui in Panama.

constans.

S. constans *Edw.* (9 f). Head, pro- and mesonota and forewing as well as the costal margin of hindwing orange-red. Antenna and abdomen bluish black, distal margin of forewing and the hindwing black. The black marginal band varies in width. Specimens which are yellow instead of orange-red are ab. **sancta** *Neum.* and *Dyar* (9 f). — Arizona and New Mexico.

basirei.

S. basirei *Druce* (9 f). Like the following species only known to me from *DRUCE*'s description and figure. Black; both wings with yellow costal margin. — Mexico: Vera Cruz.

semifulva.

S. semifulva *Druce* (9 g). Almost like *basirei*, but the hindwing yellow with black marginal band. — Mexico: Vera Cruz.

11. Genus: **Harrisinopsis** *gen. nov.*

♂. In the forewing 12 veins, subcostals 3 and 4 stalked, 5 originating near the 1st radial, in the hindwing 7 veins, all free, costal anastomosing with the cell for a short distance, the connecting vein between the costal and subcostal about as long as half the diameter of the cell, very oblique, upper angle of cell not produced further distad than the lower one. Antenna very stout, pointed, middle branches of pectinations about twice as long as the diameter of the shaft. Foretibia with stout spur. — Genotype: *H. robusta* *spec. nov.*

robusta.

H. robusta *spec. nov.* (9 g). ♂: Antenna and body dull greenish blue, abdomen dull green, forewing above bluish green, upper side of hindwing and underside of both wings brownish black with greenish blue gloss in an oblique view, the metallic gloss everywhere faint. Tongue orange-red. — Amazons, 2 ♂♂ in the Tring Museum. A densely scaled, opaque species distinguished by a very stout body.

12. Genus: **Harrisina** Pack.

Forewing with 11 or 12 veins (in the former case subcostal 3 = vein 9 absent), subcostals 2, 3 and 4 stalked, more rarely only 3 and 4, or 2 and 4 (when 3 is absent). In the hindwing 7 veins, connecting vein of costal and subcostal quite short, sometimes the costal and subcostal stalked, the cross-veins usually only slightly angled or not at all, on the whole oblique, as the upper angle is further distal than the lower one. Foretibia with or without spur. Abdomen without long double tail, but with short tufts of hair laterally and at the apex. — The early stages only known of 2 North American species.

A. Forewing with 11 or 12 veins, subcostal 2 always stalked with the next vein: *Harrisina*. s str.

a. Wings quite unicolorous, without yellow markings.

z) Collar yellow or red.

H. americana Guér. (9 g). Foretibia without spur. Brownish black, with faint metallic purplish blue gloss, collar yellow or orange-red. Forewing with 5 subcostals, of which 2 to 4 are stalked (GUÉRIN's specimen in the Tring Museum). Specimens with only 4 subcostal branches (subcostal 3 absent) are ab. **texana** Stretch. Larva in 2 forms: — 1. In July to August on vine, gregarious, at first entirely pale yellow with white hairs; later sulphur-yellow with black warts, prothorax black with yellow edge; disperse before pupation and spin a small whitish tough cocoon. The moth appears in the same year or in the following spring. — 2. On *Lonicera*. Dorsally yellow with black incisions, on each segment a purplish brown transverse band, on which the warts are placed, the bands connected with a broad purple-brown lateral stripe, lateral fold white from segment 6 onward. — Atlantic States, southward to Texas.

H. australis Stretch (9 g). Like the preceding, but the yellow or reddish yellow of the collar extends to the head and mesonotum and is also present beneath, sometimes the whole forecoxae and a part of the forefemora yellow. Specimens of this form also occur with only 4 subcostal branches. Larva like the aforementioned 2nd form of *americana*. — South-Eastern States: Florida and Missouri. Perhaps only a geographical form of *americana*.

H. ruemelii Druce (9 g). Foretibia without spur. Dull blue-black, upper side of head, the collar and the anterior portion of the mesonotum yellow. Forewing with 11 veins, subcostal stalk short, upper median branch at $\frac{3}{5}$ between the lower median and the third radial, i. e. more proximal than in the preceding species. — Mexico: Vera Cruz, Durango.

H. metallica Stretch (9 g). Foretibia with spur. Glossy greenish blue; collar red. — New Mexico and Arizona.

H. charax Druce (9 g). Foretibia without spur. Forewing with 12 veins. Blue-green. Collar carmine. Forewing black, with a faint blue gloss. — Mexico: Guerrero.

H. elongata Druce (9 h). Blue-black, collar yellow. Wings brownish black, somewhat transparent, faintly metallic. Forewing with 12 veins; in the hindwing the subcostal branch and free part of the costal vein together from the upper angle of the cell. — Mexico: Guerrero.

H. dantasi Schaus. Dull black, collar with an orange spot on each side. — Brazil: Nova Friburgo. Not known to me.

β) Collar dark like the rest of the body.

H. coracina Clem. (9 h). Dull brownish black, with slight bluish green gloss. Foretibial spur very small or absent. — Texas.

H. brillians Barn. and McDun. (= *coracina* Dyar, nec Clem., err. determ.) (9 h). As glossy greenish blue as *H. metallica*. Foretibia with distinct spur. Larva yellow, nuchal shield, a transverse band on segments 3 to 12, and the anal plate black, the bands unequal in length, between them purple spots. On vine. — New Mexico and Arizona.

H. guatemalena Druce (9 h). A small species. Dull black. Wings subdiaphanous. Foretibia without spur. Forewing with 11 veins, stalk of subcostals 2 and 4 (3 absent) very short. — Guatemala, 1 ♂ in the British Museum.

H. mexicana Schaus (9 h). Not known to me in nature. A small dull black species with semitransparent hindwing. Pectinations of antenna longer than in *americana*. — Mexico: Vera Cruz.

H. tersa Druce. Body black, very slightly bluish. Antenna greenish black, distinctly incrassate distally, with very short pectinations. Foretibia without spur. Wings transparent, narrow, the margins of both

wings narrowly black, the cellular and submedian folds of the forewing likewise black, with faint purple sheen. Forewing with 12 veins, subcostals 2 and 4 stalked; in the hindwing the costal and subcostal on a short stalk, the cross-veins very oblique, not angled. Length of forewing 11 mm. — Mexico: Vera Cruz.

chalcina. **H. chalcina** *spec. nov.* ♀: Dull bluish green, distinctly glossy in an oblique view. Pectinations of antenna pointed, the longest of them only slightly longer than the shaft is broad. Foretibia without spur. Wings more strongly rounded distally and posteriorly than in *americana*, broader, semitransparent; forewing with 10 veins, as in the right forewing 2 subcostal branches and in the left a radial and a subcostal are absent, in the left wing the two middle subcostals stalked; the lower median branch much more proximal than the first subcostal in both wings; in the hindwing the costal and subcostal on a short stalk, the cross-vein between this stalk and the next vein deeply and almost acutely angled, the upper arm of the angle twice as long as the lower, the radial and median veins further apart than in *americana*. Length of forewing 13 mm. — 1 ♀ in the Oxford Museum (ex coll. WESTWOOD) from Mexico.

virescens. **H. virescens** *Hmps.* (9 h). ♂: Slightly glossy, body blue-green, forewing more purplish blue; hindwing semitransparent, brownish black with purple gloss. Abdomen with a small red lateral stripe at the base. Forewing with 12 veins, narrow. Foretibia without spur. — Brazil: Petropolis.

janeira. **H. janeira** *Schaus* (9 h). Like the preceding, but the 2nd and 3rd abdominal segments red. — Brazil: Petropolis. Not known to me in nature; perhaps not specifically different from *virescens*.

venata. **H. venata** *spec. nov.* (9 h). ♂: Body uniformly dull greenish blue. Foretibia with spur. Wings semitransparent, forewing bluish green with the veins more densely scaled, outer margin half as long as the wing, hind angle distinct, 12 veins, the lower median less proximal than usual. Hindwing with very narrow dark margin, and dark fringes, the scaling the same in colour as on the forewing, but sparse. The underside of the forewing paler than the upper, the costal margin of both wings strongly metallic green-blue, fringes dark blue-green as above. Length of forewing 11 mm. — 1 ♂ from Santa Catharina, Brazil.

invaria. **H. invaria** *Wkr.* (9 i). Narrow winged and small. Blue-black, the upperside of the forewing, the apex of the hindwing and beneath also the apex of the forewing purple; hindwing and abdomen black, with slight green and purple sheen. Forewing with 12 veins, connecting vein of subcostal and costal of hindwing short. — Santarem, Amazonas.

lepta. **H. lepta** *spec. nov.* (9 i). ♀: Body blackish blue, wings purple-blue, antenna bipectinate, the teeth stout, the middle ones scarcely as long as the diameter of the shaft, the latter very slightly incrassate distally. Foretibia without spur. Forewing with 12 veins, subcostal 1 and median 2 rather far proximal, median 1 near the angle of cell; hindwing small, subcostal and costal stalked, apex of cell very oblique, median 2 near 1, the two veins almost 3 times as far apart at the margin as at the cell. — 1 ♀ from the Rio Agnaca Valley in West-Colombia, found by A. H. FASSL at an altitude of 2000 m.

tergina. **H. tergina** *spec. nov.* (9 i). ♀: Dull greenish black. The central pectinations of the antenna somewhat longer than the diameter of the shaft. Foretibia without spur. Wings semitransparent, with dark veins, the scales much more deeply incised than in the two preceding species, and the fringe-scales more deeply slit. Forewing with 12 veins, median 2 far proximal, median 1 almost in the middle between median 2 and radial 3, in the hindwing the subcostal branching off from the cell, cross-veins from the subcostal to the lower angle very slightly oblique, angled before the 2nd radial, 2nd median approaching the first, which is in the middle between the 2nd median and 3rd radial. Length of forewing 13 mm. — 1 ♀ from Rio Dagua, West-Colombia, collected by F. W. H. ROSENBERG.

lustrans. **H. lustrans** *Beutenm.* (9 i). A large broad-winged species. Body and upperside of forewing blue-green, hindwing and underside of both wings purple-blue. Forewing with 11 or 12 veins, median 2 far proximal, 1st median approaching the angle of the cell, in the hindwing the apex of the cell strongly angulate. — Colorado and Mexico (Mexico City, teste DYAR).

cyanea. **H. cyanea** *Barn. and McDun.* Much smaller than *lustrans*, deep metallic blue or green. Forewing with 11 veins, subcostals 2 and 4 stalked (3 absent); in the hindwing the costal and subcostal on a short stalk or originating from the cell close together, upper angle of cell produced somewhat further than the lower. — Arizona.

chalestra. **H. (?) chalestra** *Druce*, described as *Procris (?) ch.* as follows. “Male. — Head, antennae, thorax, abdomen, and legs bluish black. Primaries semihyaline black, darkest at the base; secondaries hyaline, broadly black at the apex and round the outer margin. Expanse 1 inch”. — Costa Rica; in coll. DRUCE, which has lately been acquired by Mr. JOICEY.

aversus. **H. (?) aversus** *Hy. Edw.* Described as *Triprocris*. Not known to me; its position is questionable. “Primaries, lower side of all the wings, and upper side of abdomen bright greenish black. Secondaries above, and all the rest of the body dull black. The wings are narrower and longer than in any of the allied species. It is nearest to *T. atrata* French, from Arizona. 1 ♂. Exp. wings 28 mm. Length of body 9 mm”. — Mexico: Vera Cruz. — “*T. atrata*” is a nom. in litt.

b. The forewing with at least a yellow discal spot.

H. fulvinota *Btlr.* (9 i). Brownish black, with slight purple gloss. Sides of pronotum and of abdomen, *fulvinota*, as well as a triangular discal spot on the forewing yellow. Foretibia without spur. — Southern Brazil.

H. eminens *Schaus* (9 i). Similar to *fulvinota*, but the base of both wings also yellow and the discal *eminens*, spot of the forewing usually larger. The yellow markings varying in extent. — Brazil: Tijuca.

B. Forewing with 12 veins, subcostals 1 and 2 free, 3 and 4 on a long stalk: *Nesace*, *Kirby* (= *Pampa Wkr.*, *Btlr.* preocc.). The figure of the venation which BUTLER gives is erroneous: *Journ. Linn. Soc., Zool. XII*, t. 28, Fig. 13 (1896).

H. mystica *Wkr.* (9 i). Purple-black, without markings. The light spot on the forewing mentioned by *mystica*. WALKER is due to loss of scaling. Antenna stout, distinctly incrassate distally, pectinations longer than the diameter of the shaft, slightly clavate, cross-veins of hindwing obliquely rounded, not angulate. Wings semi-transparent, more densely scaled towards the base. — Honduras, 1 ♀ (type) in the British Museum.

H. splendens *spec. nov.* (9 k). A large species. ♀: Body and upperside of forewing metallic green, *splendens*, the fringes bluish; hindwing above glossy blue, beneath both wings glossy blue-green. The middle pectinations of the antenna more than twice as long as the diameter of the shaft. Foretibia without spur. Median 2 of forewing widely separated from 1. Length of forewing 17 mm. — 1 ♀ from Cuzco, Peru, May 1901 (GARLEPP), in the Tring Museum.

13. Genus: **Stylura** *Burm.*

Distinguished from *Harrisina* by the two long caudal appendages which are present in both sexes, and usually consist of a stout proximal portion and a thinner distal one, but are sometimes almost evenly slender.

S. forficula *H.-Schäff.* (9 k). Metallic greenish black-blue, slightly glossy. Wings semitransparent, *forficula*, with dark veins. Judging from the small number of specimens I have been able to examine more closely, there are several forms. But the differences (in colouring, shape of wings and venation) are so slight that it is not advisable to introduce any new names at present. *S. cirama* *Druce* from Guatemala and Chiriqui in Panama, described and figured as *Harrisina*, also belongs here. — Mexico to Southern Brazil, also from the Leeward Islands.

14. Genus: **Setiodes** *H.-Schäff.*

Antennae incrassate distally, bipectinate. Wings very narrow, forewing with 11 veins, hindwing without innermarginal veins, 6 veins from the cell including the costal, radial 2 absent. In the forewing subcostal branches 1 and 2 on long stalk. — Only known from Cuba and the Bahamas.

S. nana. The smallest American Zygaenid known. Body with white spots. Forewing with transparent *nana*, spot below the cell and a white discal spot. Two subspecies. — **nana** *H.-Schäff.* (= *pygmaeus Grote*), from Cuba, has a white spot on the hindwing. — In **bahamensis** *Dyar* (= *albinacula Hmps.*) (9 k), from the Ba- *bahamensis*, hamas, the white spot on the hindwing is absent. The larva on *Ampelopsis*; bluish white, with 7 narrow purple-brown longitudinal lines (1 median, and on each side 2 dorsal and 1 subventral), the lines connected by a transverse band on segment 5, anterior and posterior segments light red, on the penultimate segment 2 small ocelli on each side. — Although GROTE does not mention the white spots in his description of the body of *pygmaeus*, DYAR is probably correct in uniting *pygmaeus* with *nana*.

15. Genus: **Urodopsis** *gen. nov.*

Tongue and palpi well developed. Antenna (♂) bipectinate-dentate distally. Foretibia without spur, hindtibia with one pair. In the forewing 11 or 12 veins, all free, or radial 3 and median 1 on a short stalk, subcostal 1 and median 2 far proximal. In the hindwing 6 veins, the subcostal and the upper radial branch (veins 6 and 7) absent, the cell bounded costally by the intracellular vein, and not connected with the costal vein (the cross-veins are partly obsolescent also in the forewing), only 2 innermarginal veins present, the 3rd (posterior one) absent. — Genotype: *U. subcoeruleus Dogn.*

U. subcoeruleus *Dogn.* (9 h). Black, with very slight green gloss, the head almost entirely golden green, *subcoeruleus*, strongly glossy. Wings semitransparent with dark veins, with blue sheen in a lateral view, greater part of hind-

wing vitreous. The abdomen ends in a thin truncate tuft of hair-scales. — West Colombia; A. H. FASSL found the species (only ♂♂?) in the bed of a river on wet stones.

pusilla. **U. pusilla** Wkr. Smaller than *subcoeruleus*, without anal tuft. Antenna and upper side of body metallic blue (wings strongly worn). — Venezuela, 2 ♀♀ in the British Museum.

Beside the forms mentioned above, the three following ones possibly also belong to the Zygaenids. As they are not mentioned among the Syntomids, Lithosiids or Arctiids in HAMPSON's Lep. Phal., we here append descriptions of them. The species are unknown to me and the information given by the various authors about their structure is insufficient to identify the family to which the species belong.

chlora. **Lycomorpha chlora** Schauf., Nung. Otiosus p. 11 (1870): Forewing above and underside of both wings green with blue edges, hindwing blackish; antenna filiform, blue with white apex. Expanse 24 to 29 mm. — Venezuela.

desertus. **Lycomorpha desertus** Edw., Papilio 1, p. 81 (1881): Sexes different. — ♂: Wings orange with broad black marginal band, the inner margin of which is almost straight, not curved. Palpi and base of tibiae orange, antenna, abdomen and tarsi black. ♀: much larger than the ♂; thorax and abdomen above and beneath, tibiae and tarsi orange, antenna blackish. Forewing orange with 2 black transverse bands; hindwing orange with black marginal band. Expanse: ♂ 20 mm, ♀ 32 mm. — Arizona. The two specimens were caught in copulation; they have disappeared. The species probably belongs to the *Lithosiinae*.

gundlachiana. **Ira gundlachiana** Neumoeg., Ent. Amer. 6, p. 64 (1890): Thorax and proximal half of abdomen rose-red, abdomen beneath white with black bands. Wings rose-red with black margins, forewing with 2 and hindwing with 1 white dot, forewing moreover with black vein-stripes and black discocellular spot, hindwing very small; with vitreous longitudinal stripe. — Cuba. Seems to belong to the Syntomids. Tibiae without spurs.

In *Urodus monura* H.-Schäff., *imitata* Druce, *modesta* Druce, *xylophila* H.-Schäff., which appear in KIRBY's Catalogue among the "*Pyromorphinae*" (i. e. the American Zygaenids) a small cell is separated from the apical part of the cell of the forewing by an oblique vein running from the subcostal to the discocellular veins, as is frequently the case among the Tortricidae; these species, moreover, have two pairs of long spurs on the hindtibia, which does not occur in any American Zygaenid. These forms are Tortricidae. *Aperla tineiformis* Wkr. (1856), of which the type is in the Oxford Museum, is identical with *Urodus monura* H.-Schäff. (1854).

3. Family: Syntomidae.

Referring to the comments published in Vol. II (p. 37—38) and Vol. X (p. 61—62) upon this rather homogeneous family of butterflies, I remind the reader of the historical note appended there on the development of our knowledge of the Syntomid forms. To the statement made there, according to which in 1892 (KIRBY's Catalogue) little more than 700 Syntomid forms were known, which number, however, went up already in 1898 (HAMPSON) — six years hereafter — to 1200 and in 1912 (at the publication of the Indian part of our work) to more than 1400, we may now add that we know to-day already more than 2000 *Syntomidae*, of which more than 1800 pertain solely to the American fauna.

If we consider that altogether only 4 species of this family of butterflies are living in Europe, but that almost at no place of Europe there occur more than 2 *Syntomidae* or 3 at most, and that they are absent altogether in many districts — in contrast with the American abundance —, the chief characteristic of the fauna of the warmer parts of America thus becomes evident to us. I say „warmer“, for in the temperate part of the western hemisphere we do not notice any abundance of species nor of specimens of *Syntomidae*. At another occasion we have already remarked that almost the whole of the great number of *Syntomidae* in America is massed together in the tropical part of this continent. In South and Central Mexico it occurs yet in numbers, but to the north they decrease rapidly and, except Florida and the southernmost United States, we only meet with 3 more common forms in the northern part of America, *Scepsis fulvicollis* (26 a), *Lycomorpha pholus* (26 d), and *Ctenucha virginica* (26 g), all of which exhibit dark colours. In South America the number of *Syntomidae* decreases just as rapidly in the polar direction: in South Brazil they are still numerous and in some genera, such as *Antichloris*, *Ctenucha* etc. they still remind us of the abundance of species of the palearctic *Zygaenidae*, but near Buenos Ayres they have already dwindled away to quite few, mostly not common species, in order to disappear completely in Southern Argentina.

The otherwise homogeneous family of the *Syntomidae* still offers a greater variety in the exterior by an extremely detailed mimicry according to most various models, which has also led to divergent secondary modifications. Already when commenting upon the palearctic *Syntomidae* we have hinted at these multifarious imitations. Among the insects serving them as models the relatives of the genus *Zygaena* were the best protected, since these butterflies are in fact attacked by no other enemy of insects except by spiders *). Furthermore several extremely spinous, very aculeate Hymenoptera are favourite models which are shunned with evident dislike even by large animals. We consequently have a zygaeniform group also in the palearctic *Syntomidae*: the *S. phegea*-group having *Zyg. ephialtes*-forms as their models; and secondly the *Synt. germanus*-group imitating yellow-curved wasps. In almost the very same way as the yellow-curved wasps (which are by far superior in number in the palearctic district) recede behind the black and blue *Crabronidae* in the American Tropics, we also find, on glancing over our tables 10—26, that the yellow-banded species are by far inferior in number to the dark-blue, black, or metal-lustrous species.

It is difficult to understand the attempts made again and again just in the *Syntomidae* to contest the serviceableness of such masking. The objection that the disguisings are able to deceive mankind living outside of nature, but by no means an animal living on insects, is entirely wrong and has been so often disproved by experiments that one can hardly understand how it is possible to revert to it again and again. Not only reptiles are deceived and shrink back from them, because they are without the intelligence necessary to conceive the deception, but also insectivorous monkeys not disdaining insectile food, consequently the most intelligent vertebrates, treated an *Aegeria apiformis* I offered them alive, as a wasp **), and they would undoubtedly have treated in exactly the same way a just as well masked *Syntomidae*. Even the savage thinks that the wasp-like butterflies are able to sting, and children in Ceylon, as well as young coloured natives in Brazil are just as much afraid of the wasp-butterflies as of the wasps themselves. The objection that the differences in the behaviour between the model and the copy may be found out by observation, does not hold good in unintelligent animals the actions of which are merely reflex actions caused by the impression obtained by means of the eye.

*) According to statements by Mr. H. BURGEFF, lizards on being fed immediately spit out *Zygaena* which they had greedily snatched up, and afterwards wiped off their mouth energetically several times.

**) Zoologischer Anzeiger 1893, No. 427.

To believe that the enemy is to be kept off by the masking — for instance a spider, Mantis, lizard, bird or the like — and is able to consider that an insect swarming 2 or 3 m above it must be an (edible) *Syntomidae*, because its original, the (more dangerous) Hymenopteron flies nearer to the soil and is not used to fly so high, is a so-called „anthropism“, i. e. a conclusion due to the mistake of assigning human intellectual power to animals.

In a special work on South American *Syntomidae*, C. SCHROTTKY recently turned particularly against the arguments in Vol. V, p. 6, where among other examples of mimicry particularly also the wasp-imitations of the *Syntomidae* are mentioned. Beside some objections having been disproved long ago, there is a relatively new objection made, that the relative rareness of the imitators argue in favour of the futility of the mimicry. But the old observers who laid down the theory of mimicry, have based their theory upon this very rareness which they alleged in favour of the protective theory, since only if the really protected animals are superior in number, an efficacious protection results from the masking. Animals occurring in great numbers, such as the cockchafer, are in no way protected and need not be protected, since they do not die out owing to their prolificness. Consequently just what argues in favour of the protective theory, is here applied for the refutation, and in doing so, SCHROTTKY has also quite overlooked that it is just the lack of specimens of an animal species which is particularly advantageous for a quick, conspicuous and vast transformation. E. HAASE even mentions the rarity of the imitators as a distinctive mark for the decision which is the model and which the copy. Also the fact that a bug, as for instance *Spiniger ater* which is able to sting itself, evidently imitates the *Pepsis*-wasp, is said to argue against the theory of a protective imitation by the *Syntomidae*. We must, however, remark that the *Spiniger* are clumsy insects and in spite of their (feeding-) spike very helpless, but that the *Pepsis* is able to sting all round its body with an almost incredible dexterity and thus represents a quite incomparably more dangerous animal — without counting a great difference in the intensity of the effect of the spike (the *Spiniger* has almost no poison at all).

The fact that the mimetic masking is not quite universally carried through in the *Syntomidae*, has also caused the conclusion that it is superfluous. Since the non-mimetic *Syntomidae* have also withstood the struggle for existence — it was inferred at least — it was not to be understood why the mimetic ones should require this protection. It is, however, neither to be conceived why some ruminants require big horns, others small ones and others again none at all; it cannot be understood why in some animals both sexes are armed, in others, however, only the males. The stag has its antlers from February to October, which are absent during the rest of the year, or which are then so sensitive that they even hinder and imperil it. How would the inference be drawn from this fact alone, that it does not serve it as a useful weapon? Whosoever wishes to be convinced of the serviceableness of the antlers of a stag, may, after having without any risk approached an ever so powerful hind or an antlerless stag, once enter a deer park where there are stags with fully developed antlers. He may also be present at the manipulation often necessary in zoological gardens of embarking well-armed stags, of seizing and removing them, of separating them in their fights etc. etc., and he will have to own that the antlers are not alone a useful, but an almost crafty defensive weapon; and that it is so, in spite of not all the species of stags being provided with them, and though not both sexes, and the males only being temporally provided with them.

Starting from this view, we may divide the *Syntomidae* into two large groups: into such representing an exact copy of other insects, so exact that the original serving as the model may immediately be pointed out; and into such as having on the whole an awe-inspiring exterior, but which may still not be regarded as the immediate copy of certain dangerous insects. To the first group belong, in the palearctic fauna, for instance the *Syntomis phegea* mentioned above, copying a *Zygaena*, to the other group the genus *Dysauxes* in which, we may recognise a type being on the whole little like a butterfly, but more like a saw-fly, for which, however, we are not able to name an insect as its truly copied model. In the Indian fauna, the Syntomid genera *Syntomis* (Vol. X, t. 10, 11) are opposing each other in an imitative manner whilst the *Euchromia* (Vol. X, t. 12) are similar to the original. The same contrast is also met with in America, where we immediately recognise for instance in the *Macrocneme* a copy of the wasp-genus *Pepsis*, in some *Isanthrene* the copies of clearwinged hawk-wasps, in *Pseudosphex* and *Sphecosoma* the copies of social wasps, but where on the other hand many genera exhibit only indistinctly a „hymenopteroid“ exterior, not that of certain aculeata, or even where whole genera, such as *Napata*, *Eucereon*, *Empyreuma* etc. show an exterior deviating from the lepidoptera-type, though not hinting at any distinct originals.

The habits of the nearly 2000 American Syntomid-forms are of course very different: to such an extent that there are hardly common characteristics to be found applicable to all. One may only say as much as that most of them are day-butterflies, appearing particularly when the sun begins to shine very brightly after a copious rain and being in eager search for blossoms abounding in honey, as for instance in South Europe the *Zygaena*-species. The skirts of woods, clearings in the forests, and sunny slopes of mountains are the places, where you may be sure of capturing numbers of *Syntomidae* at any season in Tropical America. If among

many, otherwise numerous exploits (as for instance the so-called Bogotá-exploits) there are relatively few *Syntomidae* found, it would be wrong to infer therefrom a scarcity of *Syntomidae* in these districts, since the mostly unintelligent (Indian) collectors are subject to being deceived by mimicry in just the same way as the enemies of the butterflies are, against which the masking is directed. Whoever glances over the numerous new species which are established here in the following pages from Colombia, and considers which great part originates from the exploit of one collector — of Mr. A. H. FASSL at Teplitz —, will be able to estimate what enormous treasures of *Syntomidae* are still to be brought to light, if the upper course of the great tributaries of the Amazon River will once be more minutely examined with regard to more insignificant insects.

It is just in the level, damp-hot lowlands, where the *Syntomidae* gather in particularly great numbers. The fact that just in the almost extremely prolific Syntomid country of Colombia, according to FASSL near Bogotá, this group of butterflies is only very sparsely found, shows us that in a vertical direction the same rapid and often sudden decrease of *Syntomidae* takes place as towards the higher latitudes. In Santos, being at a low altitude and close to extensive swamps, the Syntomid fauna is very much more abundant than in the neighbouring, though higher elevated São Paulo; just like at the more elevated suburbs of Rio de Janeiro, where it appears again more copiously than near Petropolis high up in the Organ Mountains, where I sometimes did not get sight of any Syntomid at all in excursions lasting several days, what hardly ever occurred near Rio and never near Santos. According to an account by Prof. Dr. DRAUDT, in Mexico, owing to the orographical formation of the country, southern forms go far up to the north on both the coasts along the temperate and hot altitudes, whereas on the high plateau of the interior northern forms go far to the south; this is very well to be followed up as far as the valley of Mexico. There are no confines here between north and south, but in the greatest part of the country a division into western and eastern forms which are equalized again only in the south, towards the Isthmus of Tehuantepec. The reason for this is to be found in the entirely different hygrological conditions of the two coast districts. The eastern coast has no real dry period at all, whereas on the western coast absolute aridness is prevalent in winter. The range of the *Syntomidae*, therefore, naturally is the greatest in the districts of the eastern coast between 3000 and 1500 m, where the luxuriant vegetation is never intermitted during the whole year owing to the incessant humidity, for which reason one generation follows here the other. The western coast and the highlands of the interior, on account of the desert-like character, has only very few species thriving only in the oasis-like depressions and glens.

The conduct of the different Syntomid species frequently depends on their mimetic relations. A disguise is, of course, then most effective, if not only the exterior shape, but also the demeanour, the way of flying, the attitude when being at rest etc. are adapted to the model. This is the case in many species in so excellent a way that merely by these peculiarities of the attitude and conduct the mimetic pendant would have to be recognized. Already in Vol. X (p. 62) I have mentioned that a *Trichura* (*Tr. dixanthia*, 18 d) being common near Santos, has a yellow spot at the side of the 3rd abdominal segment, over which, when being at rest, the hyaline wings are placed in such a way that it appears at those places, where in the *Pimpla*-like model-wasp the mark of the wings (called stigma or carpus), being distinct in most of the Hymenoptera, is found. The female *Pimpla*-wasp, however, has besides a thicker and particularly strong ovipository sting, because the ichneumons of this genus prick more pupae than larvae and therefore, in order to pierce also the cocoon, need a particularly strong and long sting. This sting, being one of the most conspicuous organs, must be imitated, which is done in the *Tr. dixanthia* by a thread-like chitinous appendage attaining the thickness necessary for the deception by means of densely arranged scales. In *Tr. cerbera* (18 d), approximating this species, this appendage sometimes grows so long that it exceeds the length of the whole animal. In a similar way we find, in the genus *Macrocneme*, the hind-tibiae monstrously thickened by a pinnate scaling, so that the genus was denominated hereby. The most interesting fact, however, is that the owner of these legs succeeds in becoming entirely similar to the model — the crabronidae *Pepsis* — by means of letting these long legs hanging long down when flying, so that its harmless, velvety, little paws are trailing along exactly like the spinous prehensile feet with which the wasp uses to carry about its victims — enormous spiders of the forests or roads. The blue *Pepsis*-wasp, vulgarly called *marimbondo* by the Brazilians, may certainly be considered the most dreaded insect of the districts there. It even easily vanquishes birdspiders, and natives told me repeatedly that children may die from its stings. Thus it is quite comprehensible that all kinds of insects of different orders agree in copying this rapacious animal, as for instance beside the Reduviid *Spiniger* mentioned above, also the grass-hopper *Scaphura nigra*.

In models from the group of the fold-wasps, the costal margins darkened by folding the wings on the one hand, the strangulation of the waist on the other hand, are to be exactly copied in order to become mimetically similar, and the degree, in which this is performed by certain *Pseudosphex*, precludes any casual similarity: compare for instance *Ps. steinbachi* (10 e), *klagesi* (10 d) and their allies. *Phaeosphexia opaca* (10 c) exhibits a shape of the body which deviates from nearly all the Lepidoptera by the abdomen being differently shaped, and which would be unexplainable unless the animal assumes the resemblance of a wasp by a freak of nature. *Bombopsyche ruatana* (10 k) represents a tiny bee; *Pompilopsis tarsalis* an Eumenid. The most favourite model, however, is the said *Pepsis*. Among its imitators and other Syntomid genera, being somewhat allied to each

other, I mention besides the *Macrocneme* also the *Antichloris*, *Pompiliodes*, *Saurita*, *Calonotus*, *Psoloptera*, *Ichoria*, *Eriphioides*, *Horama*, and *Pseudopompilia*-species. As in many districts 2 species of wasps belong to the most common *Marimbondos*, one of which has quite blackish-blue forewings, the other such with white apices, we also have two different types of imitators: *Pompiliodes aliena* with, and *Pomp. tenebrosa* without white apices of the wings; *Macrocneme evelina* with them and *Macr. lades* without them; *Pterygopterus leucomelas* with and *Pt. caeruleus* without them, and so on. To the imitators of quite different insect-orders belong yet the *Correbia* and *Correbidia*, as well as single species of *Dycladia*, which have copied the uneatable species of coleopters of the soft-winged genus of *Colobothea*.

As regards the habits of the *Syntomidae*, it is easily comprehensible that they are not the same in all the more than 1800 American species. It seems also that the behaviour is not the same in the different countries. SCHROTTKY, for instance, reports that in Paraguay the *Syntomidae* are the most common in the dense forest. The contrary is the case in Brazil, where the *Syntomidae*, like all the diurnal butterflies, are absent altogether on account of the lack of flowers. On the other hand, they bustle about on open hillsides, on the slopes of mountains, on clearings, and on broad roads; at any rate I have gained the impression that they in any case need sunshine which is entirely absent in the dense woods.

As SCHROTTKY infers from this behaviour the inefficiency of the masking of the *Syntomidae*, the actual behaviour of the mimetic species must be also dealt with here. SCHROTTKY furthermore concludes that the theory of the protective mimicry is disproved by the fact that the *Syntomidae* are timid butterflies. „If indeed“, he argues, „any protective effect is produced by the similarity to valiant wasps, this would be expressed by the behaviour of the animal and the butterflies themselves would show their confidence in their mimicry by being to a certain degree phlegmatic“. What is missed here by the observer, I have been able to observe in fact in so great a number of American *Syntomidae* that I must consider it to be common to all the mimetic forms. Not one Syntomid known to me is difficult to capture; many may simply be taken with the hands, or they scarcely fly off; certainly they are not more timid than their patented models. The *Pepsis* wasps, it is true, in spite of their fearful venomous sting, also fly off on approaching them uncautiously; they are even much less confident than their European allies *Ammophila sabulosa*, *Psammophila viatica* etc. swarming about before our feet on sunny roads. I cannot make out which of the mimetic *Syntomidae* SCHROTTKY has meant in his observations; he only mentions the *Macrocneme*, and with respect to them I must absolutely contest the behaviour stated by him. The only true fact is that the animals, when flying, exhibit a swift flight (exactly like their models!); but when they sit on a blossom, one may often capture one specimen from a bush, without the one next to it taking to flight.

Some *Syntomidae*, however, are so daring that they do not even fly up on being touched, but move their abdomen in a wagging way, with their wings being spread, consequently just as if they would wish to threaten thereby, as also some of our *Aegeriidae* do. Already in dealing with the *Syntomis*-species of the *germanus*-group (Vol. II, p. 38) I have mentioned that the *Syntomis* copy even the jerking movements of the model wasp (*Polistes*), and this also applies to very many American species.

I have thought it necessary to deal with this matter particularly exhaustively, because a real disproof of the explanation of the protective mimicry would render the exterior and the biological behaviour of most of the American *Syntomidae* incomprehensible; all the other commentaries one has tried to give with respect to its exterior being unlike a butterfly have not been able to stand the ground of a logical examination and do not throw any light whatever on many biological peculiarities making the presumption of a protective mimicry easily comprehensible.

Although most of the *Syntomidae* (in contrast with very many butterflies of Tropical America) seem to be bound to a certain season, still members of the family are met with rather all the year round. The time when most of the Brazilian trees are blossoming, seemed to me to be also the height of the season for the *Syntomidae*; on such blossoming trees, I found particularly the larger species, *Isanthrene*, *Homoeocera*, *Cosmosoma*, *Gymnelia*, *Mesolasia*, and the like. *Trichura*, *Tipulodes*, *Ctenucha*, *Napata* are fond of sitting on umbels, about in the attitude of our *Zygaena*, and *Macrocneme*, *Dinia*, *Antichloris*, *Pseudomya*, *Psoloptera* love bushes covered with blossoms. Even the small Papilionaceae growing in low bolsters of blossoms and replacing in America our *Thymus*, are much frequented by some low-flying forms, as we have them before us in certain *Abrochia*, *Diptilon*, *Loxophlebia*, *Pheia*, *Chrostosoma*, *Leucotmemis* and many others.

Particularly favourite plants for *Syntomidae* are furthermore the Senecio-species, also Eupatorium, Vernonia, Solidago, and similar herbs; sometimes *Syntomidae* are gregariously met with there, and the said blossoms seems to be for the American *Syntomidae* the same what the thistles and scabious are for the *Zygaena*-species with us. JÖRGENSEN has observed that *Syntomidae* were sucking up the sap of Senecio to which the stings of Hymenoptera on the stalk and leaves of the plant provided access.

Although the *Syntomidae* love the day-time and the sun, yet they also fly at night and like to go on

the electric light by which, for instance, KARL E. HOFFMANN has captured in Mexico all the species hitherto known from there. The flight commences at about 9 p. m.

The American *Syntomidae* are often extremely local, some species being bound to particular slopes of mountains, clearings in the woods, banks of rivers, and the like. The flying-place sometimes amounts to but few square fathoms, and often it is a single blossoming tree or a certain bush which we may day by day successfully search for a certain species. This behaviour might be considered to be somewhat analogous to that of the *Erycinidae* likewise representing small, often metallic-glistening, elegant and extremely local butterflies, and it is interesting to remark that also in these Rhopalocera a great number of American forms (more than 1000) are opposed by about 200 Indians and but 1 from Europe proper; a strange zoogeographical analogy!

Extraordinarily little is known about the life-history of the American *Syntomidae*. The larvae are not very rare and I remember of having very often found the velvety-haired larvae being provided with long, projecting hair-tufts on the front and hind part of the body, running about on walls and rocks. But only very exceptionally I succeeded in breeding them. Many seem to be monophagous or oligophagous, at least they would not accept any of the foodplants given to them; nor does the search for pupae provide us with any clue in this respect; the cocoons being often very fine and similar to a small, woolly bird's egg, are to be found much more frequently in clefts of the rocks, beneath wall-covers and flat stones than spun to the leaves of the food-plant. Still the lack of our knowledge may often be due to the fact that the mostly insignificant representatives of this family of butterflies being scarcely indigenous in Europe are met with but very little special interest, as I have said already elsewhere.

With respect to the morphology, the neurulation is to be remarked upon as particularly important. The fact that members of distantly separated genera often have the same model — for instance the *Euagra*- and *Agyrta*-like forms, or the imitators of *Cosmosoma stibostictum* —, naturally also causes secondary congruences among the different imitators, and in such cases the neurulation, as a rule, must be examined in order to remove doubts and mistakes.

In Vol. II it was already mentioned that the resemblance of the *Syntomidae* to the *Zygaenidae* is merely external and may in some cases be due to mimicry; it is quite unlikely that the two families are closely allied; this is proved, beside many other facts, particularly by the behaviour of the larvae. There exist, however, relations to the *Arctiidae*. The *Eucereon* and *Halisidota* are not very remote from each other, and also in the *Automolis* and *Belemnina* we may observe certain transitional forms. In delimiting these families we follow the excellent catalogue of Sir GEORGE HAMPSON, on which also all the important works hitherto have been founded.

The head is rather small with relatively short palpi projecting but little beyond the head and mostly protecting a strong sucker, the antennae of medium length or long, nearly always distinctly doubly combed, sometimes mimetically altered, seemingly thickened by scaling and feathering, ringed in white, distorted, or rolled wasp-like. Eyes bare, semiglobular, rather small; forehead broad. Thorax with distinct seams, sharply defined collar, projecting patagia above which there are often strongly secreting neck-glands. The dorsal covering often metallic, frequently with very much velvety hair or also smooth as a mirror. Abdomen likewise very often with variegated markings, coiled, with metallic spots, at the end often hemochrome or orange-yellow warning-colours. The first abdominal rings in the ♂♂ of many genera bear ventrally a large valve extending in some *Pheia*-species almost to the end of the abdomen. The legs are mostly strong, often adorned with trousers, hair-tufts or feathers, the hips frequently (in the ♂♂ oftener than in the ♀♀) with a white, red, or metallic lustre, the tibiae usually with spurs of medium length. Forewing lancet-shaped, rather pointed, frequently similarly shaped to those of *Hymenoptera* and then often hyaline in order to attain a still greater resemblance to them; the hindwings always small, oval, sometimes only a tiny scale; sometimes they are so rudimentary that they are unable to use them for flying, and the forewings perform the flight alone. Most of the *Syntomidae* are about the size of the European species of the family, i. e. the size varies between that of a *Dysauxes ancilla* and of a *Syntomis phegea*. The neurulation on the hindwing is often considerably reduced, a characteristic mark of the family is the absence of the costal vein (vein 8) which, however, in the forms being more closely allied to the *Arctiidae*, may occasionally be present as a short rudiment not reaching the costal margin. The forewing always has a closed discocellular. As to further particulars see the diagnoses of the genera *).

1. Genus: **Phaeosphecia** Hmps.

The only species which exhibits a great external likeness to *Pseudopompilia mimica* Druce (21 k), is distinguished by a strongly strangulated second abdominal segment, an abdomen being abruptly expanded

*) There are some words yet to be said with respect to the copulation-apparatus exhibiting in the ♂♂ of many tropical genera such an asymmetrical structure as probably in hardly any other family. The asymmetry is effected by the stunting of a valve, while on one side between the uncus and valve a peculiar, smaller or larger appendage is inserted pretending to be a valve and belonging to the IX. tergite. Thereby the one valve is displaced more ventrally. But there occur also symmetrical valves with the said appendage being developed on both sides, which is presumably analogous to the anal appendage found by DAMPF in the *Olethrentinae*. (M. DRAUDT.)

behind the stylus and then running to a point, a well developed sucker, erect palpi with long scale-hairs at the 1st joint; the short ctenodont antennae being serrate at the ends are above in the middle set with thick and rough scales. The neurulation of the wings similar as in the following genus, but on the forewings both the upper subcostal veins are petioled, the lower radial vein and the upper median vein do not approach each other. On the hindwings the subcostal and the uppermost radial are unpetioled, the lower median vein and the lowest radial are standing on a long petiole, the middle radial and the upper median vein are absent; the cell is very narrow, the transverse vein short and oblique.

opaca. **P. opaca** Wkr. (= *vespa* H.-Schäff.) (10 c) is unicolorously bluish-black with a metallic lustre; the shaft of the antennae above and the 2nd abdominal ring laterally and beneath whitish. The hindwing exhibits below the base of the cell a small, triangular hyaline spot. Known only from the Amazon (Pará, Sa. Catharina).

2. Genus: **Orcynia** Wkr.

Large and robust with a well-developed sucker, erect palpi with a short, obtuse terminal joint. The long, narrow forewings are distinguished from the allied genera by both the upper subcostal veins rising separately from the cell, while the lower radial and the upper median vein likewise rise separately, but run very near and parallel to each other for about half their length, the upper median vein rising close at the lower cell-angle. Forewings as in the preceding, but the subcostal and the upper radial vein are short-petioled.

calcarata. **O. calcarata** Wkr. (10 c). The sole, hornet-like species has dark-brown wings; the inner-marginal vein of the forewing has a steel-blue reflection particularly towards the margin. The body is black. The anterior area of the palpi, forehead, vertex, collar, covers of the shoulder-covers, thorax and anterior hips are yellow-spotted like the 3 first abdominal rings. Antennae and ends of the posterior tarsi orange-brownish. Occurring in Brazil (Amazon, Pará) and lying before me also from East Colombia from the Upper Rio Negro (Coll. FASSL).

3. Genus: **PseudospheX** Hbn.

Smaller, ichneumon-like animals of mostly dark colours with the abdomen strongly strangulated at the base, whereby the habitus of the wasps is most deceptively copied in single species. The palpi, being steeply appressed to the head, are very hairy downward, like a beard. The ♂ exhibits on the ventral side a large valve covering the 2nd and 3rd segments. The neurulation is not quite constant in the species. The two lower radials and the upper median vein of the forewing rise from one place, the lowest subcostal vein rises nearer to the apex than the third.

strigosus. **P. strigosus** Druce (10 c) resembles the *Amycles*-species with the exception of the strangulated abdomen; the whole animal is blackish-brown, which colour turns more reddish towards the light, diaphanous apical spot. The forewings also exhibit 2 diaphanous streak-spots below and behind the cell. On the forewings the lower median vein rises from the cell-angle. In Mexico it was found in the States of Vera Cruz, Tabasco, Jalisco and Yucatan, as well as in Guatemala; the species flies together with the Hymenoptera *Parachartergus apicalis* from which it is hardly discernible at a hasty glance.

sericeus. **P. sericeus** Schrottky. (The figure denoted as *sericeus* on t. 10 c does not represent this species, but *P. polybia* Kaye.) Somewhat larger than the preceding, and distinguishable by the wings being dusted in a rusty brown and being hyaline outwards below the anterior median vein, as well as by the two first, light-brown coloured abdominal rings. The body is otherwise black; the palpi inside and at the apex brown; the hind part of the head and the upper surface of the thorax sparsely, the middle of the antennae more abundantly scaled in a metallic blue; the base of the antennae whitish, the apex brown. Legs light brown with darker femora and white forehips. The first abdominal ring exhibits above a velvety-black basal spot, the ventral valve being white-margined. Expanse of wings: 26 mm. From Paraguay.

causa. **P. causa** spec. nov. (10 c) greatly resembles *strigosus* in its exterior, but as the lower median vein rises farther down, it belongs to the following group and is at once distinguishable by the blackish-brown costal part being but slightly lighter towards the apex: the apex of the wings remains brown. The antennae are scaled in an intense metallic blue, somewhat longer ctenodont and the terminal third being shorter and more compact in proportion to *strigosus* is white. The very long-bearded palpi are proximally rusty-brown; the forehead with greyish white hair. The hindwings are somewhat lighter than in *strigosus*. — Described according to a ♂ from the Upper Cauca-Valley (Colombia, 1000 m). Type in the Coll. FASSL.

polybia. **P. polybia** Kaye (10 c, as *sericeus*) has a black head and thorax. The eyes are finely margined by white; the two basal thirds of the antennae are bluish-black, the thinned apical third dull black. The black abdomen exhibits at the strangulated segment laterally an oblique, white streak. The yellowish-hyaline forewings are broadly scaled in brownish in the costal part; the hindwings yellowish-diaphanous. Legs yellow with a velvety-black inner side of the femora. Expanse of wings: 26 mm. Brazil (Castro [Paraná]) in April.

pellax. **P. pellax** spec. nov. (10 c) approximates *polybia*. The body is black, the head, particularly near the forehead and collar, interspersed with coarse, bluish-silvery hairs; the 3 first abdominal rings above with a

chestnut-brown lustre. Ventral valve brown, like the 3rd ventral segment margined by silvery white, at the 2nd segment laterally an oblique white streak; the posterior margin of the 2 or 3 next ventral segments is orange-brownish. The ventral sides are intensely iridescent in a metallic blue. Legs orange-yellow, hips and ends of femora silvery-white, the femora inside and above dark brown. The faintly yellowish hyaline wings exhibit brown costal- and inner-marginal stripes, the apical third of the forewing is sealed in a greyish-brown down as far as the middle radial. A ♂ from the Amazon (BANG-HAAS) without the antennae; the antennae in the figure are restored.

P. noverca *Schaus* (10 d) has a black body being covered with sparse, whitish-grey, small hairs which are somewhat denser on the forehead and at the collar. The antennae are black; the forehips are silvery white, the legs for the rest black except the under surface of the hind tibiae and-tarsi which are yellow-brownish. The basal two thirds of the costa and proximal margin of the hyaline forewings are jet-black, the cell thinly sealed in brown, which sealing gradually disappears towards the apex. In the submedian space, in the middle between the base and the rise of the lower median vein, there is a brownish oblique band. Common from August to November and from March to May on compositae in South Brazil, Paraguay and Argentina.

P. jonesi *Kaye*. Head black, the eyes finely margined by white; the two basal thirds of the antennae are purple-black, the thinner terminal third brownish. Abdomen above lustrous brown, beneath the segments are margined by yellow. Wings faintly yellowish-hyaline. Legs yellowish with darker femora. Expanse of wings: 20 mm. — Brazil (Santos) in March.

P. exsul *Rothsch.* (10 d) the patria of which is uncertain, probably originating from Brazil (Rio de Janeiro or Sa. Catharina), is a small, jet-black species, only the legs are orange-brown. Ventral valve edged in grey. The diaphanous wings are orange-brownish in the basal two thirds, while the apical third is of a more greyish tinge. Costal and proximal margins brown.

P. klagesi *Rothsch.* (10 d). Head black; collar orange-yellow; shoulder-covers striped in orange-yellow; the brown thorax exhibits posteriorly a transverse yellow band. The first 3 abdominal segments are dark red-brown, the others black. The legs are reddish-brown, the forehips and tibiae white; antennae black. The hyaline wings exhibit a dark-brown costal-marginal half and at the base a similar inner-marginal stripe. Venezuela (Caura River) in June.

P. garleppi *Rothsch.* (10 d) is a somewhat larger species with a black body. Collar yellow, so are the shoulder-covers which exhibit a black median stripe; metathorax with a yellow transverse stripe. Forehips and ventral valve white; anterior tibiae black, tarsi yellow; middle- and hind-hips black, tibiae and tarsi yellow. Antennae red-brown, at the tips yellow. The hyaline wings have narrow red-brown margins, the apex of the forewing, from the cell-end down to the middle radial, is brown. Described from Bolivia.

P. aurifera *Klages*. Head and thorax dark-brown; antennae orange-brown, in the thickened part with a purple reflection; both the last joints of the palpi, the forehead and head behind the eyes grey-haired, neck, collar and thorax covered with golden-yellow hairs. Legs orange-brown, forehips darker. Abdomen orange-brown, the 2nd segment laterally and below silvery-white, as well as the lateral spots and hind-margin at the 3rd segment. Wings yellowish hyaline with brown veins and fringes; forewings above the median and the middle radial vein dusted in brown, as well as the 2 basal inner-marginal thirds. This species with an expanse of 28 to 30 mm was described from Venezuela (Suapure), but it also occurs in Colombia.

P. caurensis *Klages* (10 d). An easily recognizable, larger species. Head and thorax, antennae and legs brownish orange-yellow, forehips silvery-white; the lower part of the forehead and the hind enclosure of the eyes white, the vertex exhibits a black spot. The 3 first abdominal rings brownish-orange, the rest of the abdomen black with a purple reflection. The first abdominal ring exhibits subdorsally black lines, the posterior half of the 4th is curled in yellow. The ventral valve and the 3rd ventral segment are margined by silvery white. The yellow-hyaline forewings are thinly sealed in yellow-brownish at the costal and proximal margins and outward of the discocellular as far as down to the middle radial; this part as well as the antennae, on being placed oblique to the light, show an amethystine reflection. Venezuela.

P. steinbachi *Rothsch.* (10 e). Likewise a larger species greatly resembling the preceding. It differs by its one-coloured golden-yellow head and orange-yellow forehips; the 2 first abdominal rings are chestnut-brown, the third one exhibits a black transverse band, the others are quite black (in *caurensis* the 4th shows yet a yellow hindmarginal ring). In Venezuela apparently not rare; known also from Bolivia.

P. polistes *Hbn.* (= *eumenides* *Newm.*) (10 e) has a one-coloured, reddish yellow-brown abdomen without any markings; the head and thorax are black and yellow marked. The wings are faintly yellowish hyaline, in the apical half down as far as the middle radial dusted in brownish. Widely distributed from Mexico through Guatemala, Venezuela as far as Brazil (Amazon, Pará, Matto-Grosso). — In **v. melanogen** *Dyar* described from Mexico (State of Vera Cruz) the abdomen is black with yellow hindmargins of the segments, the yellow colour of the thorax is confined, too, and there occur transitions to the typical form, the black colour of the abdomen being brightened up to brown.

- laticinctus*. **P. laticinctus** *Hmps.* (= *fasciolatus* *Druce*) (10 c). The body is yellow; the palpi are black-banded, the forehead is whitish with a black band between the antennae; collar, shoulder-covers and thorax striped in black. The first abdominal ring is black-striped in the middle and on the lateral tubercles; the other segments exhibit black transverse bands. The hyaline wings are darkened by yellow-brownish in the costal-marginal half down as far as the middle radial. The species flies in Guatemala.
- deceptans*. **P. deceptans** *Zeruy* (10 e) differs from *laticinctus* to which it is very closely allied, by unicolorously lemon-coloured palpi and forehead and the much narrower, yellow hindmarginal bands of the abdominal segments, and at the collar the fore- and hindmargins are yellow. — Described from Brazil (Blumenau in Sa. Catharina); a specimen undoubtedly belonging hereto is before me from Colombia (Muzo), from the Coll. FASSL.
- ichneumoncus*. **P. ichneumoncus** *H.-Schäff.* (= *polybioides* *Burm.*) (10 e) one of the most ichneumon-like species with a black, somewhat purple-lustrous abdomen. The antennae are brownish or black with a purple reflection. The yellow-brownish hyaline wings, being somewhat opalescent, have brown veins. — In the typical form *crabronis*. the wings are for the most part covered with black-brown hair-scales which are absent in ab. **crabronis** or only quite faintly indicated in a light brownish; the latter form seems to be more common. From Central America through Brazil to Paraguay, Uruguay and Argentina.
- hyalozonus*. **P. hyalozonus** *Fldr.* (10 d) resembles the following species by its size, but it is immediately recognizable by quite black palpi and more intensely blue-lustrous forewings with a hyaline inner margin. The forehead is grey, the abdomen beneath at the first segment spotted in whitish, both the first segments below narrowly margined in white. The hindwings are hyaline with fine black veins and margin, and the costal margin is dusted in dark brownish-grey. Colombia (Bogotá).
- rubripalpus*. **P. rubripalpus** *Hmps.* (10 e) is a large, strong species with a dull greenish-black body, at once recognizable by the conspicuously red-coloured palpi and forehips. The wings are dark blackish-brown with a purple-violet reflection. Beneath the cell-base of both wings there are narrow hyaline stripes. Brazil (Santos).

4. Genus: **Sphecosoma** *Btlr.*

It differs from the preceding genus by the upper median vein of the forewing rising below the radial veins; the third subcostal vein rises nearer to the apex than the lowest. The genus likewise contains very ichneumon-like, mostly smaller species.

- angustatum*. **S. angustatum** *Möschl.* (= *testaceum* *Druce*, *gracile* *Klages*) (10 e) exactly resembles *Pseudosphex polistes* in the colour and marking of the body; the hyaline wings have a brownish-yellow costal margin and proximal margin. From Guatemala, Panama, Surinam, Venezuela. — In **nigriferum** *Dyar* described from Mexico (State of Vera Cruz: Santa Rosa) the abdomen is blackened with yellow hindmargins of the segments; the shaft of the antennae is black; the legs have no red colouring. Flying in August.
- perconstrictum*. **S. perconstrictum** *Zerny* greatly approximates the preceding and particularly the dark shape of it, and is easily discernible by the palpi being dark brown at the inner side and by the black-brown, not yellow-red antennae. The abdomen is black-brown with yellow hindmarginal edges growing gradually posteriorly narrower, the 2nd segment is below lustrous white. The wings are faintly yellowish hyaline, the costal- and proximal margins of the forewings narrowly light brown, veins and fringes of all the wings brown. Expanse of wings: 24 mm. Brazil (Sa. Catharina).
- rufipes*. **S. rufipes** *Rothsch.* (10 h) differs from the similar *angustatum* by entirely white palpi, the quite black head with a yellow transverse line behind the base of the antennae, and the black-brown, orange-curved abdomen; the first segment is red-brown. The antennae are darker, only at the apex orange. Described from Venezuela.
- aurantiipes*. **S. aurantiipes** *Rothsch.* (10 h). Palpi and forehead are yellow, the vertex black; collar yellow, in the posterior half black; shoulder-covers yellow, outside bordered by black; thorax in front black, behind yellow. The first abdominal ring is brown, the other part of the abdomen black, yellow-curved; the whole under surface is yellow, the legs orange. The hyaline wings exhibit an orange coloured costal margin and proximal margin. From Venezuela, Paraguay and Bolivia. The specimens from the latter two countries are considerably smaller than those from Venezuela.
- trinitatis*. **S. trinitatis** *Rothsch.* (10 h). Head, palpi, thorax and legs are yellow, collar, shoulder-covers and thorax black-striped; the two first abdominal segments are brownish yellow, the second one with a red-brown ring, the rest of the abdomen black, at the costal margin of the segments yellow-curved. The hyaline wings have a brownish-yellow costal margin and proximal margin. Antennae red-brown. Trinidad, in December.
- arctatum*. **S. arctatum** *Wkr.* (10 h) is recognizable by the orange-yellow abdomen curved in bluish-black; head, thorax and the 2 first abdominal rings are light yellow, with bluish-black spots and markings. The wings are hyaline with fine black veins and margins; costal margin and base of the inner margin yellow. Expanse of wings: 28 mm. Amazon (Ega).
- meridionale*. **S. meridionale** *Schrottky* is much smaller than the preceding (expanse of wings: 22 mm). Head black, on the forehead and vertex yellow-banded; palpi, collar, shoulder-covers and under surface yellow. Antennae

brown, in the middle darker with a violet-blue scaling; thorax black, marked by yellow. First abdominal ring dark-yellow with a black median line, the 2 next segments brown, the anterior one with yellow lateral margins, the 4 following ones are black with yellow rings, the last is quite black. The hyaline, iridescent wings have light-brown veins and a proximal margin dusted in the same colour; costal- and distal margins are black. Paraguay, flying in July, on blossoms of *Ageratum conyzoides* L.

S. *deceptrix* *Hmps.* (= *fasciolatum* *Druce*) (10 h). Head whitish with a black band between the antennae *deceptrix*, which are of an orange-yellow colour like the palpi and legs, only the base of the antennae is black. The body is yellow, the collar, shoulder-covers and thorax are striped with black, the abdomen with black bands. Wings hyaline with a red-yellow costal margin and proximal margin, distal margin and base of the proximal margin narrow black. Costa Rica, Guatemala, Panama, also from Peru (Marcapata) (BANG-HAAS). It differs from the very similar *cognatum* by both the lower radial veins of the forewing rising from the same place.

S. *nigriceps* *Hmps.* Head and thorax are black; palpi at the base yellow, in front with whitish hair; *nigriceps*, collar and shoulder-covers striped yellow, chest, ventral side and legs yellow. The first abdominal ring is yellow, at the sides black, the 3 next ones orange-brownish with yellow ring-indentations, the 4 last ones black, curled yellow. The hyaline wings have fine, brown veins and margins; the costa of both wings and the proximal margin of the forewings are yellow, the costal-marginal half of the latter dusted in brown. Expanse of wings: 26 mm. Bolivia.

S. *simile* *Schaus* (10 h) from Venezuela (Aroa) has a yellow body; the vertex exhibits a black spot; *simile*, the collar and shoulder-covers are margined with black, the thorax marked black. The first abdominal ring exhibits above 2 black dots, and on the lateral tubercles black streaks; beginning from the 3rd one, the segments are banded black; the black of the 4th ring extends as far as the ventral side. The hyaline wings exhibit a black distal margin being expanded to a spot towards the apex.

S. *mathani* *Rothsch.* (10 h). Head and palpi are yellow; collar orange with narrow black margins; *mathani*, shoulder-covers yellow, bordered by black; thorax yellow with a black centre. The orange-coloured abdomen with the leaden-coloured ring-indentations makes this species and the following easily recognizable. The hyaline wings are yellow at the costal margin and the base of the inner margin, the black distal margin is somewhat expanded between the upper radial and the 4th subcostal vein. From the Amazon (Teffé, captured in September).

S. *plumbicincta* *sp. nov.* (10 h) is very closely allied to the preceding species. It differs by quite black *plumbicincta*, antennae with a slight purple reflection, a large black spot on the vertex, the collar being black only at the base, but entirely orange-yellow in the posterior half, as well as by the much more extensive apical spot by which it also resembles the small *Isanthrene*-species. The whole under surface inclusive of the 3 pairs of hips is light lemon-coloured, the legs on the whole orange. The two first abdominal rings are also above lemon-coloured; the first exhibits a large, black median spot with a metallic blue centre, on each of the lateral tubercles a black streak, the second segment with a broad, black, longitudinal streak; the other rings are above orange with leaden-coloured segmental indentations; those on the 3rd and 4th rings are laterally continued downward as black transverse bands. At the base of the costal margin there is a snow-white spot bordered by black. The costal margin is hyaline in the basal third, only the subcostal is faintly coloured yellowish; only the median third of the costal margin is of a bright orange-red; the median vein is orange-yellow as far as the place from which the two lower radial veins rise, the other veins are black. The proximal margin is broadly black at the base, only at the distal base it is orange. Panama (Chiriqui, ♂ BANG-HAAS; Lino, 800 m, ♀ FASSL). Type in Coll. FASSL.

S. *melapera* *Dogn.* Head, collar, and shoulder-covers lemon-coloured, palpi with an orange-yellow *melapera*, terminal joint, antennae black; vertex black-spotted, collar in front, shoulder-covers outside bordered by black, thorax black with yellow lateral spots. The 3 first abdominal rings lemon-coloured, the others orange; the first ring exhibits a black median streak, the second a large black dorsal spot with a metallic-green reflection in the centre, next to it on both sides a black spot, the third a smaller, four-cornered spot; the other rings are black and curled in a metallic green. Under surface and legs lemon-coloured, tarsi orange, above black. Wings hyaline with black margins and a black apical spot; subcostal margin, median and proximal margin yellow. Expanse of wings: 26 mm. Colombia (Cauca River) in July.

S. *abdominale* *Schaus.* Head yellow with a brown spot on the vertex, palpi yellow with ochreous *abdominale*, terminal joints; antennae dark-brown; collar in front black, behind yellow; thorax yellow, black-spotted with ochreous-yellow, black-bordered shoulder-covers. The two first abdominal rings are yellow, the first exhibits subdorsal, black spots covered with brown scales and on each side of it a black transverse streak; the other segments are ochreous brown, beneath yellow. Legs yellow and ochreous, anterior and middle tarsi striped in black. The wings are hyaline with black veins and fringes; the costal margin of the forewings ochreous yellow, as well as the median between the 2nd median and 3rd radial; at the base of the costal margin a white dot. Expanse of wings: 27 mm. Venezuela (Caura Valley).

S. *sparta* *Druce.* Head and palpi yellow; antennae black with a brilliant red shaft; collar black, *sparta*, bordered by yellow; thorax black with a white line at the base; abdomen black, curled yellowish-white;

legs, thorax and venter light yellow. Wings yellowish hyaline, veins finely black. Expanse of wings: 26 mm. Described from Colombia.

- testaceum.* **S. testaceum** Wkr. (10 i) from British and French Guiana and the Amazon (Pará) greatly resembles *angustatum* (10 e) in the colouring, though it is easily discernible by the much less strangulated abdomen. The head is black, the palpi yellow. The antennae are yellowish-red, the shaft is in the middle for a short distance black. The costal part of the forewing is faintly brownish as far as the cell-fold.
- metamela.* **S. metamela** Hmps. is smaller than the preceding and at once distinguishable by the orange abdomen the 3 last rings of which are quite black; besides the head is yellow, only the vertex is black, the antennae are quite black; the first abdominal ring exhibits above 2 fine black streaks. The yellowish hyaline wings are dusted orange-brownish in the costal-marginal half. Expanse of wings: 24 mm. Paraguay.
- vicinum.* **S. vicinum** Schrottky is deep dark-brown on the body with single blue, interspersed scales, palpi and forehead sparsely whitish-haired; the middle of the antennae mostly scaled deep dark-blue. Legs brown, forehips yellowish. The abdominal rings 4 to 6 are light brown at the hindmargin, like the ventral side. Wings yellowish hyaline with light-brown veins; costal- and distal margin blackish-brown, proximal margin dusted more light-brown. Expanse of wings: 24 mm. Paraguay, frequently flying in July on *Ageratum*-blossoms.
- abnorme.* **S. abnorme** Hmps. (10 i) deviates from the typical forms in the veins by a well-developed, long and broad cell of the hindwing; the proximal margin of the forewing exhibits beneath, the costal margin of the hindwing above in the ♂ long and dense hair. The colour of the body is orange, on the abdomen more brownish. The vertex is black and leaden-coloured, collar and shoulder-covers black, bordered by orange, the thorax black-striped. The two first abdominal rings above blackish, the first one with an orange dorsal spot; the hind segments exhibit silvery-blue dorsal bands. The hyaline wings are finely black on veins and margins, the subcostal is orange; the black margin expands somewhat towards the apex. Expanse of wings: 30 mm. Lower Amazon (Massauary).
- nigricornis.* **S. nigricornis** Rbl. is closely allied to *cognatum* (10 i), but it differs by its unicolorously blackish head and palpi; the back of the thorax is dark, too, only at the shoulder-covers with some interspersed, orange, small scales. Legs outside brownish, inside orange; hips dark with yellow scales. Abdomen above blackish with broadly orange-banded ring-indentations. The under surface is unicolorously orange as far as the anal end. Wings hyaline. On the forewing the middle radial is brought very near to the upper one by a strong curve; the discocellular is not quite closed. Expanse of wings: 26 mm. Described according to 1 ♂ from the Central Cordilleras between Mediacon and Ibagué.
- cognatum.* **S. cognatum** Wkr. (= *fasciolatum* Btlr.) (10 i). Body light-yellow, palpi and legs more orange, the latter black-banded, forehead white, base of the antennae black; collar black-bordered, shoulder-covers and thorax black-striped; the two first abdominal rings are dorsally and subdorsally black-striped, the other segments black-curved. The wings are hyaline with fine black veins and margins, the costal margin and base of the proximal margin yellow. Expanse of wings: 26 mm. Mexico, Colombia and Amazon. — The species differs from the very similar *deceptrix* (10 h) by the two lower radial veins of the forewing rising separately.
- meerkatzi.* **S. meerkatzi** Strand deviates from the preceding by its black antennae; forehead, palpi and legs are just as yellow as the body, not orange; only the anterior and middle tarsi are above dark; the wings are brown-yellowish hyaline. Expanse of wings: 21 mm. Brazil (Maranhão).
- melissa.* **S. melissa** Schaus (10 i) has quite black antennae. Head and thorax marked black and yellow, forehead and a band across the vertex white. The abdomen is black and yellow banded. The hyaline wings have narrow black margins, a black apical spot and at the base some orange colouring. Known from Brazil.
- surrentum.* **S. surrentum** Druce (10 i) has a yellow first abdominal segment with 3 black longitudinal stripes which are connected at the hind-margin by a black transverse beam, the 2nd segment exhibits orange-yellow lateral spots, the rest of the abdomen is black. Head and thorax are orange and black. The yellowish-hyaline wings have a narrow, blackish costal margin. From Bolivia and Peru.
- ecuadorum.* **S. ecuadorum** Druce (10 i) is distinguished by the carmine costal margin, only the base and the extreme apex are black, for the rest the wings are hyaline with fine black veins and margins. Head and thorax are black and orange-yellow, the abdomen black except the three first yellow-curved segments. Ecuador, also from Peru (Marcapata).
- melanotum.* **S. melanotum** Hmps. (10 i). Head, thorax and abdomen are black, on the forehead and vertex intermixed with white hairs; the 2nd strangulated abdominal segment is yellow, the third, in the ♀ also the 4th, yellow-margined; legs and ventral valve yellow. The hyaline wings with very fine black veins and margins exhibit a yellow subcostal stripe, so are the proximal margin, as well as the costal margin on the hindwing, of a yellow colour. — Bolivia (Corvico).

S. albipalpe *sp. nov.* (26 i) greatly approximates the preceding and is at once recognizable by the 2nd *albipalpe*. and 3rd palpal joints being all white in front; the terminal joint is of a somewhat yellowish tinge; also the 2 first joints of the antennae are white. The body is quite black, on the head and the edges of the shoulder-covers intermixed with sparse silvery-grey hairs; also the 2nd and 3rd segments of the abdomen are quite black, the former exhibiting laterally an oblique yellow streak. Venter likewise black, only the hindmargins of the segments somewhat yellowish-haired. Legs orange-brownish, forehips lemon-coloured. The hyaline-forewings are in the discocellular somewhat yellowish; the costal margin is yellow only between the uppermost radial and the lowest subcostal vein, as well as the proximal margin in the distal half. Expanse of wings: 24 mm. According to a ♂ from the Amazon (BANG-HAAS).

5. Genus: **Pseudosphecosoma** *Strand.*

Very closely allied to *Sphecosoma* and differing merely by the presence of a very short upper median vein on the hindwing, whilst on the forewing the uppermost subcostal vein stands simultaneously with all the others on one single common pedicle. Only 1 species:

P. vespoides *Strand.* Head and thorax are yellow; a transverse band on the vertex, spots on the collar *vespoides*. and shoulder-covers are black; so is the middle of the dorsum; on the hind part of the dorsum there is a T-shaped black figure. Abdomen above brown, beneath yellow like the legs; only the tarsi and hind tibiae are above brownish. Antennae red with black indented teeth. Wings brown-yellowish hyaline with brown veins, fringes, costal- and proximal margins. Expanse of wings: 24 mm. Brazil (Maranhão).

6. Genus: **Bombopsyche** *Hmps.*

Only one, sombre species being separated from the genus *Pseudosphex* by shorter palpi, the sudden, not gradual, expansion of the abdomen behind the footstalk; on the forewing the lowest radial rises separately from the lower cell-corner, the two median veins from a place below it, the middle radial above it.

B. ruatana *Druce* (10 k) is a unicolorously black animal; on the forewing the marginal third as far *ruatana*. as down to the upper median vein is more thinly scaled and lighter; the hindwings exhibit a small narrow hyaline spot below the base of the cell. Known from Honduras (Island of Ruatan).

7. Genus: **Pompilopsis** *Hmps.*

The sole species differs from *Sphecosoma* by the second abdominal segment not being strangulated as it is there, but also the third one; behind the very thin footstalk the abdomen expands rather suddenly, in order to taper off gradually towards the apex. No essential difference in the neurulation.

P. tarsalis *Wkr.* (= *semihyalina* *Wkr.*, *vespiformis* *Herr.-Schäff.*) (10 i). The very peculiar, slenderly *tarsalis*. built animal is not to be mistaken for another species. Body dull greenish-blue-black, tarsi light-grey. On the hyaline forewings, a diaphanous brown band extends from the proximal margin before the middle to the costal margin and along the latter to the apex, a similar spot is situated at the inner-angle, cut off by the lower median vein. Transverse vein and costa deep metallic blue. Hindwings, except the hyaline base, diaphanous brown with a blue reflection. In the ♀ the brown band of the forewing does not reach as far as the apex and the spot of the inner-angle is absent. From Mexico (Tabasco) through Guatemala as far as Brazil (Pará).

8. Genus: **Pompiliodes** *Hmps.*

This genus contains some species all of which resemble more or less the *Amycles anthracina* (12 l). The abdomen is but very little strangulated. On the hindwings the two median veins stand on a conjoint pedicle with the lower radial, the upper median vein rises from the lower close before the margin; the first radial vein and subcostal pediculate or not.

P. albomarginata *Druce* (10 k) is the largest species, immediately recognizable by hyaline hindwings *albomargi-* *nata*. with black veins and a rather broad marginal band and the short double ctenodont antennae. The white apical third of the forewing is very extensive and extends as far as the inner-angle. Costa Rica and Panama, also from Mexico.

P. aliena *Wkr.* (= *flavifascia* *H.-Schäff.*) (10 k) is a true copy of *Amycles anthracina* and distinguishable *aliena*. not only by the differences of neurulation, but also by the absence of the red neck-spots and the unicolorously black-brown hindwings. It differs from the preceding species by its smaller size, dark hindwings, a marginally grey-bordered, white apical spot of the forewing and, like the following species, serrate and ciliate antennae. From Guatemala, Venezuela, Brazil (Manas, Pará, Ega) and Peru (Marcapata).

P. postica *Wkr.* (10 k) differs from the preceding species by more stretched, more pointed wings, and *postica*. the much smaller extent of the whitish marginal spot which is to be seen only between the lower radial veins

and fades away in the brownish surroundings without any bordering. The apex is grey down as far as the middle radial. The hindwings are grey, lighter and more diaphanous than in *aliena*. Known from Panama and the Amazon.

tenebrosa. **P. tenebrosa** Wkr. (10 k) from the Amazon District has still somewhat narrower and quite unicolorously black-brown wings, only the apical third is an idea lighter grey, the white brightening is absent altogether.

9. Genus: **Paramya** Hmps.

The species forming this genus are very differently composed in their exterior. A mark common to all is that the subcostal and the upper radial of the hindwing rise from one pedicle; on the forewing the upper median vein rises below the lower cell-angle sending forth the two lower radial veins.

intersecta. **P. intersecta** Hmps. (10 k) has hyaline forewings with black veins and in the marginal area internerval stripes; distal margins and proximal margin as far as the submedian fold broadly black; hindwing black with the costal-marginal area being diaphanous. The body is blackish-brown. Amazon (Pará).

aenetus. **P. aenetus** Schaus (10 k) is black on the body, with bronze-green, black-veined wings. The hindwings exhibit below the median narrow, hyaline stripes. From Brazil (Castro Paraná, Sa. Cruz).

flavia. **P. flavia** Schaus (10 k) entirely resembles a small, yellow *Cosmosoma*, recognizable by the hindwings the proximal margin of which is orange-yellow at the base, then broadly black. The ♂ antennae are long-combed. Brazil (Castro Paraná).

picta. **P. picta** Druce (10 k) is an unmistakable species with very narrow wings. The forewings are in the disc hyaline diaphanous, turning yellowish towards the smoky grey-brown apex. The base and proximal margin are orange-yellow; a triangular median spot with the point showing towards the base and a somewhat faded spot in the distal third of the proximal margin are black. The hindwings are orange with a black apex. The body is orange-coloured, head, antennae, legs, and the 4 last abdominal segments are black. From French-Guiana.

chrysonota. **P. chrysonota** Hmps. (= ? *hoffmannsi* Rothschild.) (10 k) somewhat resembles the common *Leucotmemis nexa* (13 a) and greatly deviates from the other species of the genus. Black; antennae with a white tip; forehead and collar, as well as the meso- and metathorax with metallic blue spots which are more whitish on the thorax. The abdomen shows golden-green dorsal, lateral and ventral stripes. The black forewings exhibit an oblong hyaline spot below the middle of the cell, two more are between the upper median vein and the middle radial, as well as traces above and below the upper radial, on the hindwing there is a hyaline spot below the base of the cell, some more behind the cell. From the Amazon (Itaituba). I presume that the *Calonotos hoffmannsi* described by ROTHSCHILD likewise from Itaituba belongs hereto.

10. Genus: **Homoeocera** Fldr.

Large, strong species, partly resembling humble-bees or blow-flies, with a stout, woolly-haired thorax; the antennae are thickened in the middle, here occasionally provided with a hairy cover. The cell of the hindwing is extraordinarily short, the lower radial and the lower median vein on a long pedicle. A peculiarity of many (maybe all?) male species is that the whole body, evidently only as long as the animal is fresh, is entirely wrapped up by a tangled mass of woolly, white or light-grey hair being matted into balls. This wool apparently issues from the sides below the ventral valve, where it peeps out in the shape of long locks. Before me are *acuminata*, *stictosoma* and *staminea* showing this peculiarity.

lophocera. **H. lophocera** Druce (10 k). A very imposing animal with a black body and a scarlet apex of the abdomen; on the shoulders are large, white spots. The hyaline wings have very broad, black margins, the forewings a median band. The doubly combed antennae are strongly thickened in the middle part of the shaft and exhibit here yet a thick hair-tuft. Brazil (Santos). The species is distinguishable from *Mesolasia paula* (18 d) almost only by the neuration.

gigantea. **H. gigantea** Druce (10 a) is the largest species with a deep velvety-black body and scarlet palpi and legs; the abdomen exhibits dull greenish-blue rings. The hyaline wings are broadly black at the base, the margins and transverse veins. From Guatemala and Costa Rica; also a specimen from Mexico (Misantla) with a much more extensively black apex of the wings.

leuce. **H. leuce** Maassen (10 l), placed to *Dasysphinx* by the author, to *Sarosa* by HAMPSON, I consider to be decidedly a *Homoeocera* according to a specimen before me from the Coll. SEITZ, on account of the antennae being strongly thickened in the middle. The body is brownish-black, posteriorly with a bronze-green reflection. The steel-blue legs are white at the joints and tarsi. The hyaline wings have very broad black margins and median spot. The base is black on almost $\frac{1}{4}$ of the surface of the wings with a faint green lustre. The

shaft of the otherwise black antennae is white from the middle to shortly before the tip above. The ♂ before me having been used for the figure originates from Bolivia; the species was described from Colombia.

H. duronia Druce. Head, palpi, thorax and abdomen are black, the antennae black with a white tip. *duronia*. The abdomen exhibits on the ventral side a bright, bronze-green reflection. The first abdominal ring and the last 4 segments are red-curved. Characteristic are the snow-white legs. The wings are hyaline, the forewings with a broadly black base and costal margin, a black median spot and apex; the hindwings are broadly black at the proximal margin. Colombia.

H. sandion Druce. Head and antennae black, neck and collar orange-yellow; thorax and abdomen *sandion*. greenish-black, the latter at the base and laterally banded orange-yellow; legs orange, black-curved. Wings hyaline with black veins and margins. Expanse of wings: 36 mm. Colombia (San Juan; Choco).

H. garleppi Rothsch. has a black body, the front half of the abdomen with a steel-green lustre. The *garleppi*. legs are black, the basal two fifths of the anterior and middle tarsi white, three quarters of the hind tarsi white. Forewings yellowish hyaline, the margins, base, and a discocellular spot broadly black; the hindwings are less yellow, at the base and margins black, the proximal margin grey. — The much larger ♀ has longer and narrower wings all of which are uniformly yellow. — From Peru (Marcapata and Huancabamba). Distinguishable from the similar *leuce* (10 l) by yellowish wings, differently coloured legs and the antennae being white-coloured only beneath at the tips.

H. watkinsi Druce, allied to the preceding, has a black head and thorax, and a metallic-green abdomen; *watkinsi*. neck, base of the thorax and ventral side white; the abdomen on each side shows 4 yellowish-white spots, beneath 2 red ones. Legs black and white. On the hyaline forewings the veins, the base, a spot at the cell-end and a large spot at the distal margin below the apex are black; on the hindwings the veins, a spot at the cell-end, and the distal margin are black, the proximal margin is broadly snow-white. Expanse of wings: 40 mm. From Uruhuasi in South Peru.

H. tolosa Druce (10 l). Black; vertex and collar spotted in a metallic blue; the first abdominal ring *tolosa*. exhibits large white spots, the others show metallic blue subdorsal spots, at their hindmargin there are single, interspersed, red-yellow scales; on the ventral side of the 2nd to 4th segments there are indistinct, white transverse bands. The wings are hyaline, faintly yellowish with black veins and distal margins; an orange-yellow subcostal stripe and two similar ones separated by black at the proximal margin. Described from Ecuador (Intaj).

H. sahacon Druce (10 l). The velvety-black body is spotted in a metallic blue on the forehead, vertex, *sahacon*. collar, thorax, legs and at the abdomen laterally and sublaterally; the 2nd to 4th abdominal rings exhibit lateral orange bands, and the last segment beneath an orange spot. The yellowish hyaline wings have black veins and margins, at the base of the forewing there is a blue spot, the bases of the costal- and proximal margins are orange-striped. Panama.

H. staminea spec. nov. (11 a). Body black. On the collar and the shoulder-covers on each side a *staminea*. white, metallic-blue opalescent spot, a similar one in the middle of the metathorax. The first abdominal ring exhibits above 4 large white spots, the 2nd and 3rd rings are above unicolorously mealy light-yellow, in another ♂ snow-white, beneath black. Ventral valve silvery white, from its lateral margins there emerge dense heaps of yellowish-grey woolly threads wrapping up the whole legs. Wings hyaline with narrow black margins and veins. The black margin of the hindwing projects proximally like a tooth between the proximal margin and vein 1, as well as between this and the lower median vein. Forehips white, hind tibiae white-spotted. One male specimen originates from East Colombia (Upper Rio Negro), a second ♂ from Bolivia (Rio Songo, FASSL).

H. trizona Dogn. approximates the preceding: body black, palpal base laterally white-spotted, on *trizona*. the shoulder-covers a metallic blue dot, forehips white; the 3 first abdominal segments exhibit fine, light yellow rings. The hyaline wings, somewhat milky and blue iridescent, are finely bordered by black, with black veins, at the transverse vein broader black, as well as at the proximal angle of the hindwing. Expanse of wings: 40 mm. Venezuela (Merida).

H. rodriguezi Druce (10 l) has a velvety-black body with a broadly yellow-curved abdomen; forehips *rodriguezi*. and ventral valve of the ♂ white-spotted. The hyaline wings are at the base broadly black, the veins, margins and discal band likewise black; on the hindwing the black at the proximal angle expands in two long teeth. ♂ antennae shortly ctenodont. Mexico and Guatemala.

H. crassa Fldr. (11 a) differs from the similar *rodriguezi* by much narrower yellow abdominal rings, *crassa*. white subdorsal dots on the first two segments, furthermore white dots on the vertex, collar, shoulders and in the black base of the forewing; the transverse vein and distal margin are much finer black and the male antennae are serrate in the middle, not doubly ctenodont. Costa Rica, Colombia.

H. stictosoma Druce (11 a) has a great likeness to *acuminata*, but the somewhat more stretched wings *stictosoma*. have a yellowish tinge and orange-yellow costal- and inner-marginal stripes. The black spot at the anal angle of the hindwing is much smaller and the apex of the forewing extensively black. Colombia (Muzo).

H. acuminata Wkr. (= *leucostalacta* Burm., *dalsa* Schaus) (11 a). The velvety-black body exhibits *acuminata*. on the forehead, collar, shoulders and the 2 first abdominal segments white spots margined by a metallic blue; blue spots are also on the head, on the legs and medio-dorsally, also on the abdomen, antennae black with white

tips. The hyaline wings have a black base with a blue spot, black margins and veins. The black of the margin of the hindwing expands very much between the lower median vein and the anal angle. Distributed from Bolivia to Argentina.

magnolimbata. **H. magnolimbata** *Dogn.* greatly resembles the preceding, but it is somewhat larger; different by quite black, blue-reflecting antennae; the body is much more copiously spotted white: on the metathorax lies a large white spot margined by metallic blue, beginning from the 4th ring there are white lateral spots and on the ventral side 2 rows of spots. Forehips white bordered by blue, hind tibiae white-spotted. The black distal margin of both wings expands somewhat towards the apex. French Guiana in September.

rhodocera. **H. rhodocera** *Schaus* has red antennae with yellow tips. Legs black with red tarsi; palpi black; beneath blue-striped. Head and thorax are black, on the collar there are some interspersed, blue scales; the black abdomen exhibits metallic violet-blue dorsal and lateral lines, at the first ring a yellow transverse line, and at the 2nd ring laterally a white spot and a yellow line; on the venter a white spot. Forewings yellowish diaphanous, along the costal margin brownish; veins black except the 2 uppermost subcostal veins which are of a reddish tinge; fringes dark brown, the distal margin of the hindwing near the anal angle black. Expanse of wings: 38 mm. Chiriqui.

bombiformis. **H. bombiformis** *Rothsch.* The whole body is in the ♂ olive-brownish, the last rudimentary segment orange-reddish, from which long-haired, forcipated valves are projecting; legs brown; antennae black. The ♀ differs by a quite orange-yellow under surface and a well-developed, last, orange abdominal segment. Wings yellowish hyaline, base, distal and proximal margins, as well as the apex of the costal margin are black. — From Peru (Marcapata).

11. Genus: **Neotrichura** *Druce.*

The long cell of the hindwing from the lower angle of which the lower radial and lower median vein rise unpetioled, separates the only species from *Homoeocera*; in the ♂ the strongly convex costal margin of the hindwing is turned over and provided with a cover of white, woolly hair.

penates. **N. penates** *Druce* (= *dukinfieldia Schaus*) (11 b) has a black body with metallic blue-green spots on the forehead, at the base of the abdomen, as well as lateral and sublateral rows of spots. The hyaline wings have broad black margins, in the inner margin there are 2 oblique brownish streak-spots. Distributed from Panama to Paraguay.

12. Genus: **Isanthrene** *Hbn.*

Rather many species form this group of small and large, wasp-like animals. The colours are preponderantly yellow and black, often there are blue metallic spots. The wings are almost entirely hyaline, with a narrow or without a margin. The antennae are somewhat thickened in their middle part, shortly doubly ctenodont. The palpi project beyond the head. The cell of the hindwing, owing to the discocellular running very obliquely, is so small that it is not visible from above. On the forewings the upper median vein rises far away from the lower cell-angle from which both the lower radial veins rise likewise separately, or also from the same place.

felderi. **I. felderi** *Druce* (9 l). The body one-coloured yellow; the neck, anterior margin of the collar; one transverse streak each on the pro- and mesothorax, a longitudinal streak on the metathorax, and small spots quickly decreasing in size on the dorsum of the first abdominal segments are black. At the articulation of the forewings there is a minute, white, black-margined spot; antennae black. Wings hyaline with yellow costal and proximal margins. The distal margins and an extensive apical spot are black. Distributed from Mexico through Guatemala, Costa Rica as far as Ecuador. The colour of the body varies from light greenish-yellow to brownish orange-yellow. The latter variety of colour may be separated as **aurantiaca** *form. nov.* (9 l).

schausi. **I. schausi** *Rothsch.* (10 g) differs from the allied *felderi* by the quite one-coloured, deep orange-yellow body without any black markings, and it may be merely an unspotted form of *aurantiaca*. Mexico (Huatusco).

pentagona. **I. pentagona** *Schaus* (9 l) differs from the preceding by the absence of the black apical spot of the forewing and by the broad black rings of the last 5 abdominal segments and the much smaller size. The forehead is whitish, between the antennae a black spot; collar and shoulder-covers black striped and margined; thorax with blue-black median stripes. Costal and proximal margins of the hyaline wings with reddish stripes, fringes reddish. Peru.

crabroniformis. **I. crabroniformis** *Stgr.* (9 l) has scarlet antennae and legs; the former are at the base of the shaft often more or less black. Head and thorax are black with yellow markings. The steel-blue abdomen exhibits

subdorsal and lateral yellow spots on the 4 first segments. The pair on the first ring, often also the one on the second, are connected. Forehips of the ♂ white, of the ♀ yellow. From Costa Rica, Panama, Colombia, and Venezuela. — The specimens from the latter country, to be separated as *venezuelana* Stgr. (i. l.) (9 l), *venezuelana*. differ by the black being increased, whereby, particularly at the proximal margins, the yellow is pushed back; the antennae are black to beyond the middle, only the tips are red, and on the legs the tarsi likewise turn black.

I. thyestes Druce (9 l) is easily recognizable by the yellow abdomen being scarlet at the apex and provided *thyestes*. only with narrow black ring-indentations. Legs, antennae and venter are scarlet, only the tarsi are black; forehips yellow. Only from Ecuador.

I. cajetani Rothsch. (10 a). This magnificent large species approximates *thyestes* and differs particularly *cajetani*. by the absence of the red of the abdominal apex. The legs are blackish brown, forehips white; palpi black; head golden-yellow; the antennae scarlet, at the tips orange-yellow; collar and shoulder-covers golden-yellow with black margins; thorax golden-yellow, black-banded. The golden-yellow abdomen black-curved, the last segment black with subdorsal yellow spots. The intensely yellow hyaline wings exhibit a black distal margin growing very much broader from the lower radial vein towards the apex; the basal $\frac{4}{5}$ of the costal margin are golden orange, the proximal margin black with orange-yellow stripes. 3 ♂♂ from Central America (?), Coll. FELDER (Tring).

I. ustrina Hbn. (10 a). The body is black, on the shoulder-covers and metathorax spotted yellow; *ustrina*. antennae quite black, tibiae and tarsi carmine, hips in the ♂ white, in the ♀ black. On the two first abdominal rings 2 pair of yellow spots, behind them subdorsal and sublateral rows. Wings hyaline, veins, margins, a spot at the transverse vein and a large apical spot black. Expanse of wings: ♂ 50, ♀ 60 mm. Cuba; Brazil (São Paulo).

I. melas Cr. (= *flavicornis* F., *vespoides* Wkr.) (9 m) approximates *incendiaria* (10 a), the antennae, *melas*. however, are more extensively red, head and thorax are more intensely marked in yellow, and the 4 first abdominal rings exhibit larger yellow spots. The black legs are yellow-striped. Found from Surinam to Paraguay.

I. pyrocera Hmps. (= *incendiaria* Druce) (9 m) entirely resembles *perbosci*, the antennae, however, *pyrocera*. are brighter red-yellow, the thorax is much more marked yellow, and the abdomen exhibits 4 pair of large yellow spots, in the ♀ 5. From Mexico and Ecuador.

I. perbosci Guér. (= *pompiloides* Wkr.) (9 m). A very large, strong species with orange-yellow antennae. *perbosei*. Body and legs jet-black with a varying number of lemon-coloured subdorsal spots on the abdomen; also the shoulder-covers and the collar frequently show yellow spots. Wings yellowish hyaline with black veins and margins. At the base and costal margin the brightly brownish-red colour of the under surface shows through. Proximal margin of the hindwing broadly black. The forehips in the ♂ are snow-white, in the ♀ black. In Mexico and Guatemala apparently not rare. — Usually only the first abdominal ring shows yellow spots, there occur, however, as much as 5 and even 6 dorsal spots (= *maculata* form. nov.) (9 m). *maculata*.

I. championi Druce (9 m) is a gigantic species very well recognizable by its jet-black body and bright *championi*. brown-yellow wings. The antennae are orange-red; the abdomen exhibits on the first segment two little conspicuous, yellow, small spots. The middle segments are white-spotted on the ventral side. The margins of the wings are very fine black, the inner-marginal half of the hindwing more extensively black. Beneath, the costa and veins of all the wings are scarlet. From Panama (Bugaba, Chiriqui).

I. echemon Druce (10 b) greatly resembles the preceding, on an average smaller, the abdomen unspotted, *echemon*. unicolorously black. The main difference is the black distal margin of the forewing growing broader towards the apex and being entirely absent in *championi*. Guatemala.

I. incendiaria Hbn. (10 a) greatly resembles *perbosci*, but it is easily discernible by the antennae being *incendiaria*. black, only at the tips orange-yellow. The spots on the first 4 abdominal rings are more lemon-coloured, not so orange-yellow, the first segments exhibit also laterally yellow spots beside the subdorsal ones. — The form in which there are yellow spots only on the first 3 abdominal segments has been denominated *maxima* Btlr. — *maxima*. Both the forms fly in Brazil (Rio de Janeiro, Espiritu Santo).

I. tryhanei Rothsch. (10 b). Head and palpi black, on the forehead a yellow spot; thorax velvety- *tryhanei*. black; abdomen velvety-black, the dorsum of each segment exhibits a steel-blue spot, the 3 last rings quite steel-blue; on the first segment yellow subdorsal spots, on the second yellow lateral streak-spots. The legs and forehips are black, half of the femora red, anterior and middle tibiae red, hind tibiae red-speckled, tarsi black. Antennae red. Wings yellow hyaline, the basal two thirds of the costal margin orange, the proximal margin broadly black; the black distal margin expands, from the lower radial vein, to a large apical spot. Proximal margin of the hindwing black. 1 ♀ from Trinidad.

I. columbiana Rothsch. (10 b) from Bogotá (Colombia) differs from the preceding species by considerably *columbiana*. broader forewings which are less intensely yellow, and by quite unicolorously black legs; besides almost the whole costal margin and the basal half of the proximal margin are orange yellow.

- drucei*. **I. drucei** *Rothsch.* (10 f) is a somewhat smaller species from Colombia. Head yellowish white, palpi yellow; collar, shoulder-covers and thorax reddish-yellow, striped and bordered by black; abdomen black with a steel-blue lustre; the dorsum of the 1st segment exhibits 2 white longitudinal spots with a yellow centre, the 3 next segments subdorsal reddish-yellow transverse spots. The yellow, hyaline wings are, between the veins, dusted brownish, the margins, except the costal margin, are narrowly black, a black apical spot. Base of the hindwing yellow. The legs are cinnamon-brown, middle and hind tarsi black-brown, forehips white. Antennae red-brown.
- pertyi*. **I. pertyi** *H.-Schäff.* is black on the body; the 2nd abdominal ring exhibits orange, subdorsal spots and white dots, as well as yellow lateral spots; the 2nd to 4th rings show ventrally 2 rows of bluish-white spots. The wings are hyaline, in the costal-marginal half yellowish, with fine black veins and margins; at the base of the forewing is a blue spot; a subcostal stripe and 2 stripes at the base of the proximal margin are orange. Expanse of wings: 42 mm. Brazil (Espiritu Santo).
- azia*. **I. azia** *Druce* (26 k) is distinguished from all the other species by bright metallic-green spots on the palpi, vertex, collar, metathorax and abdomen, the other part of the body is black; antennae at the tips yellow; tarsi orange. The abdomen on the two first rings is dorsally white-spotted, the 3rd ring shows lateral and sublateral, white spots. The wings are diaphanous yellow with fine black veins and margins; at the base of the forewing a green spot, a subcostal stripe and 2 stripes at the base of the proximal margin are orange. At the inner angle of the hindwing the black distal margin expands to 2 teeth. Expanse of wings: 42 mm. Guatemala.
- pelor*. **I. pelor** *Druce* (10 f) has a brown body; palpi, the sides of the forehead, and the basal joints of the antennae anteriorly yellow, vertex and collar blue-spotted. Antennae yellow at the tips. Legs black and yellow, hips yellowish white. The abdomen shows on the first 4 segments narrow yellow ring-indentations, on all the segments subdorsal and lateral spots; the ventral valve is white-margined. The faintly yellowish hyaline wings have narrow black margins being somewhat broader at the apex of the forewings. Costal margin yellow. Described from Ecuador.
- aterrima*. **I. aterrima** *Wkr.* (= *phyleis* *Druce*) (10 b) has a unicolorously black body; the abdomen shows a purple reflection; the two first segments show white lateral spots and are ventrally white-bordered. The hind hips, as well as parts of the tarsi are yellowish-brown. Antennae red-yellow, the first two thirds of the shaft above black. The yellowish hyaline wings are in the costal half orange-brownish; on the hindwings the otherwise very narrow black distal margin between the inner angle and the lower median vein is broader. Ecuador (Sarayaue), Amazon (Ega).
- mathani*. **I. mathani** *Rothsch.* Head black, spotted in a metallic blue; collar black, bordered by orange; shoulder-covers orange with a blue basal spot and black margins; thorax spotted in a black blue; abdomen black with very large, subdorsal, metallic-blue spots, at the base with a yellow transverse band; at the other rings fine orange segmental indentations, the last ring quite orange. Legs dark-brown, with metallic-blue bands, hips white-spotted. Wings diaphanous yellow with black veins, distal margin and large apical spot, costal and proximal margin orange in $\frac{4}{5}$ of their length. Expanse of wings: 38 mm. — Cundinamarca; Colombia.
- fulvipuncta*. **I. fulvipuncta** *Hmps.* (= *varia* *Hmps.* pr. p.) (10 b). Body blackish-brown, on the forehead, vertex and collar with small blue-silvery spots; antennae red-yellow; shoulder-covers indistinctly striped orange. On the first abdominal ring 2 orange dots, on the two next ones subdorsal orange spots, on the next segments subdorsal, indistinct, leaden-coloured, blue-spotted bands. On the ventral side the 1st segment shows a white transverse band, the 2nd sublateral white, and the third blue spots. Wings faintly yellowish hyaline, in the costal-marginal half somewhat darker yellow; 2 silvery-blue basal spots; costal and proximal margin orange-brown, distal margins narrowly blackish. Panama (Chiriqui, Lino).
- varia*. **I. varia** *Wkr.* (10 b) strikingly resembles the preceding species and differs above all by the presence of yellow (not orange-brown) spots only on the two first abdominal rings, not on the third; the silvery-blue spots on forehead and collar being present there are absent here, but on the other hand there is here a blue spot, beside the one on the vertex, on the metathorax; the antennae are red-yellow, the first $\frac{2}{3}$ of the shaft above black. On the ventral side the 2nd segment shows a white transverse band, the 3rd and 4th segments exhibit sublateral white spots, the 5th blue spots. Amazon (Pará); Rio de Janeiro.
- joda*. **I. joda** *Druce*. Body black, hind head, mesothorax, and spots on the last abdominal segments deep ultra marine blue; the 4 first abdominal rings margined by light yellow. Antennae black. Wings yellowish hyaline; base, proximal margin, fringes and an apical spot are black. Antennae black. Peru, Bolivia. The species shows a likeness to the *Cosmosoma lucens* *Dogn.* figured on t. 10 a, though it is larger.
- basifera*. **I. basifera** *Wkr.* (= *grenadensis* *Btlr.*) (10 a). Black; the antennae at the tips and beneath orange; forehead, collar, metathorax and legs with metallic blue spots, tarsi orange yellow. The two first abdominal rings above yellow, the following ones subdorsally and laterally blue-spotted. Wings slightly yellowish diaphanous, at the base there are two metallic-blue spots; costal and proximal margins orange; distal margin and a large apical spot black. Venezuela (Merida), Colombia, Bogotá.

I. basiferoides *Strand* is closely allied to the preceding, distinguished by a narrower black marginal *basiferoides*. band of both wings, at the base of the forewing is only 1 blue spot, forehead and metathorax are quite black, as well as the antennae; the 2 first abdominal rings have narrower white-yellow transverse bands. Expanse of wings: 42 mm. Peru.

I. crabronides *Dogn.* (10 f). Head and thorax black, spotted in yellow. On the vertex and mesothorax *crabronides*. metallic violet-blue spots. Abdomen brownish orange, the 4 first segments black-curved. Antennae yellow-brown; legs yellow, the tibiae above and the tarsi blackish. Wings yellowish hyaline, in the costal marginal half down to the middle radial vein darker yellow. Only the extremest fringes are black, on the hindwings, towards the proximal angle there is somewhat broader black colouring. In Colombia apparently not rare.

I. atrizonata *Dogn.* (10 f) seems to be a very variable species, for before me are two specimens differing *atrizonata*. from each other, which do not coincide entirely with the original description, one of which has been diagnosed as *atrizonata* by the author himself. Palpi black with a yellow terminal joint; forehead and base of antennae yellow, vertex black intermixed with metallic blue scales. Neck yellow; collar black and yellow, shoulder-covers black, bordered by yellow; thorax black and yellow spotted. Abdomen black with subdorsal and sub-ventral, metallic blue macular series, each segment with yellow bands. The legs are black with blue spots, the tarsi yellow. The wings are yellowish hyaline, at the base of the forewing with a metallic blue spot. Veins and distal margins narrowly black, the latter somewhat broader towards the apex of the forewing, as well as towards the proximal angle of the hindwing. — In one of the specimens before me only the 3 first abdominal rings are yellow-margined, the rest of the abdomen is spotted in black-blue; in the second specimen, however, the rest of the abdomen is quite yellow, only the 3 first rings are black-banded and blue-spotted, the 4th segments exhibits subdorsal black spots. From East Colombia (Medina, 5000 m).

I. dorsimacula *Dogn.* (10 f) is a rather little, stoutly built species; palpi and head are yellow, the vertex *dorsi-* blackish. Antennae yellowish brown; thorax yellow and black spotted, on the metathorax metallic blue scales. *macula*. The first abdominal ring is almost quite light yellow, the following segments black with subdorsal, blue spots and orange-yellow median spots increasing in size posteriorly, so that beginning about from the 4th segment orange-yellow belts are formed; the last segments are almost quite orange. Wings yellowish hyaline with very narrow black margins; at the base tiny blue spots. From East Colombia (Medina, 500 m).

I. notipennis *Btlr.* (10 g). Head black, forehead white, on the vertex blue scales, the palpi yellow and *notipennis*. the antennae orange. The thorax is black and yellow striped; legs orange with small black spots. The abdomen is black, the two first segments whitish-yellow and orange-red banded, the others show metallic blue subdorsal stripes. The wings are yellowish hyaline, the forewing in the costal half as far as down to the middle radial orange-brownish, the base of the proximal margin likewise orange. The narrow black distal margins grow somewhat broader on the hindwing between the proximal angle and the lower median vein. Amazon (Villa Nova).

I. profusa *Hmps.* (10 g) is very closely allied to the preceding species and differs chiefly by the more *profusa*. extensively yellow colouring of its body. Head and thorax are orange, the latter black-striped; forehead whitish; the antennae are orange, at the shaft partly black-coloured. At the abdomen the 4 first rings are entirely orange, only narrowly margined by black; the rest is coloured as in the preceding species, also exhibiting blue lateral spots. The wings are lighter than in *notipennis*, the black spot of the proximal angle of the hindwing sometimes bordered by orange. Brazil (Ega, Sao Paulo).

I. vespiformis *Btlr.* (10 g) likewise greatly approximates *notipennis*; it differs from the two preceding *vespiformis*. species by its larger size and narrow yellow belts on the 4 first abdominal rings, the one on the 3rd segment being the broadest; the 4 first segments are beneath entirely yellowish-white. The forewings are in the costal half not so dark as in *notipennis*. From the Amazon District (Villa Nova).

I. porphyria *Wkr.* (= *machile* *H.-Schäff.*) (10 g). Head yellow, palpi, antennae and legs orange; collar *porphyria*. and thorax yellow, striped in black, on the metathorax metallic blue scales. Abdomen black with a purple lustre; the 3 first segments show orange-coloured rings, the fourth a yellow one, on which there are ventral, white spots. Subdorsal and sublateral, metallic-blue spots. The yellowish hyaline wings exhibit at the base of the costal margin a small black and metallic blue spot; costa and basal half of the proximal margin orange; the narrow black distal margin expands, from the lower radial vein, to a large apical spot, it also projects proximally between the submedian fold and the lower median vein. From Surinam to the Amazon District, reported also from Peru.

I. minor *Btlr.* (= *bromus* var. *Wkr.*) (10 g) is one of the smallest species resembling *felderi* (9 l). It *minor*. has a black head, the forehead and spots above the eyes are white. The rest of the body is yellow, shoulder-covers and thorax black-striped; on the abdomen black segmental lines. The narrow black distal margin of the hyaline wings expands to an apical spot. A subcostal stripe and the base of the proximal margin are orange. Described from Brazil, the patria not being precisely mentioned.

monticola.

I. monticola Schaus (10 g) has an ochreous-yellow body. Palpi with a black terminal joint; antennae white with a black basal half and tip. Collar and thorax black-spotted; the first abdominal ring shows above and laterally black spots, the other segments black intersegmental spots. The wings are hyaline with ochreous-yellow veins and margins; the latter at the apex and proximal angle broader ochreous-yellow, proximally bordered by black; at the base of the subcostal and inner-marginal vein there are short, black streaks; on the hindwings the veins and proximal margin are finely black. Expanse of wings: 34 mm. Costa Rica (El Sitio), also from Panama (Lino).

13. Genus: **Hyda** Wkr.

It is very closely allied to *Isanthrene* from which it differs only by shorter palpi, the short and stout abdomen, comparatively broader and shorter wings, as well as by the antennae being only in the middle part thickened and serrate-dentate.

basilutea.

H. basilutea Wkr. (= *xanthorrhina* H.-Schäff.) (11 b) is a very characteristic, unmistakable species. The body is lemon-coloured, very strangely contrasted by the orange-coloured parts: collar, shoulder-covers and the abdominal segments 5 to 7. A spot on the hind head and metathorax, subdorsal spots on the first abdominal segment, as well as dorsal spots on the following segments are black. The hyaline wings have a broad, orange base; close at the base of the costa we notice a yellow and black spot. Margins of the wings and veins narrowly black, apex of the forewing and anal angle of the hindwing more extensively black. The species is distributed from Colombia to Brazil. — From West Colombia (Rio Aguaca Valley, 2000 m) there is a local form before me: **f. aguacana** form. nov. (11 b) (type in Coll. FASSL) being distinguished by its larger size and quite unicolorously lemon-coloured abdomen, without the black dorsal spots of the typical form. The black apical spot is greatly reduced.

aguacana.

14. Genus: **Autochloris** Hbn.

A well characterized group of equably looking, more than medium-sized, very stoutly built species. The broad hyaline wings mostly exhibit a very strong, black neuration and extensive, black margins. On the forewings the uppermost subcostal vein rises from the cell, the upper median vein distinctly below the cell-angle. The cell of the hindwing is well developed and visible from above. The shaft of the antennae is thickened in the middle part. In contrast with *Homoeocera*, the woolly hairing of the thorax is absent.

capistrata.

A. capistrata F. (= *selecta* H.-Schäff.) (11 b) is one of the smallest species very easily recognizable by the entirely scarlet abdomen with triangular black dorsal spots, a black thorax with an orange collar and shoulder-covers; most characteristic, however, are the black patches on the wings, which are entirely strewn over with metallic silvery-blue scales, whereby the species greatly resembles *Phoenicoprocta eximia* (12 c) which, however, has but very little red on the abdomen. — The species was described from Brazil (?), but it lies before me from the Antilles, Porto Rico, for which reason it probably has the same range as *eximia*.

carminata.

A. carminata Hmps. from the Bahama Islands may be merely a form of the preceding with a carmine collar and shoulder-covers, of the same colour are the palpi in front; thorax and legs striped in carmine. The abdomen is of a deeper carmine, and the white sublateral spots being rather large in *capistrata* are here much smaller; the venter is black-banded, the neck white. Expanse of wings only 32 mm.

jamaicensis.

A. jamaicensis Schaus. Head and thorax black, on the collar and shoulder-covers carmine-striped intermixed with small white hairs, partly with a metallic blue lustre. Abdomen carmine with a black median stripe and black hind-margins of the segments; beneath light brown; legs black, blue-striped; tarsi white-curved. Wings hyaline with black margins; the forewings with a broad black apex, a large black spot at the cell-end and a smaller one in the middle of the cell, not reaching the median. The hindwings are bordered by black, too. Antennae black with yellow tips. Expanse of wings: 39 mm. Jamaica.

jansonis.

A. jansonis Btlr. (11 b) is the most variegated species: the abdomen is above on the first ring yellowish-white, the other rings exhibit broad, metallic blue, subdorsolateral spots, between them orange-red segmental bands, the last rings are above quite orange. The wings are yellowish hyaline with fine black veins and very broad margins. Costa Rica and Panama. — In **bogotana** form. nov. (= subsp. 1. Hmps.) the orange dorsal bands disappear more or less and remain to a slight degree only subdorsally. The ventral valve and the following segment are white, the following rings beneath yellow. Colombia (Bogotá).

*bogotana.**bijuncta.*

A. bijuncta Wkr. (= *consociata* Wkr.) (11 b) has a black body; vertex and collar are blue-spotted; shoulders and sides of the metathorax exhibit white spots. The first 2 or 3 abdominal rings show subdorsal bluespots, the three last segments are orange-yellow; into the first of them the black colour of the body extends as a dorsal spot. The hyaline forewings, like in the following species, exhibit a black transverse beam in the submedian space below the middle of the cell. Amazon (Ega).

A. proterva *spec. nov.* (11 c) has an entirely black body. Vertex, collar and the sides of the 2nd and 3rd abdominal rings are spotted in a metallic blue. The forehead, on each side a spot below the collar, and lateral spots at the 1st abdominal segment are white; the 7th abdominal ring is posteriorly at the sides narrowly margined by red. Antennae, legs and the under surface one-coloured black-brown. The hyaline wings exhibit broad black margins and a black transverse beam between the proximal margin and median before the middle of the cell. Described according to 1 ♀ from French Guiana (type in Coll. DRAUDT). *proterva*.

A. flavipes *spec. nov.* (11 c) is rather closely allied to *cuma* from which it differs by the yellow coloured under surface of the 5 last abdominal rings; the whole last segment, as well as the hind-tibiae and tarsi are entirely ochreous yellow. The white dorsal spots of the two first segments are adjoined by large orange-yellow lateral spots. The black transverse beam between the median and the proximal margin is absent, but it is indicated by a punctiform thickening at the former. Between the submedian fold and the proximal margin there is an ochreous-yellow stripe; the proximal margin of the forewing is likewise yellow-coloured. Described according to 1 ♂ from East Colombia (Rio Negro, 800 m). Type in Coll. FASSL. *flavipes*.

A. cuma *Druce* (11 c) is particularly in the female one of the largest species with a black body; vertex and collar spotted in a metallic blue. Shoulders, thorax and forehips white-spotted. The lustrous blue abdomen exhibits laterally large, triangular, scarlet spots, the last 4 rings are beneath quite red. On the two first rings there are subdorsal white spots. The hyaline wings are broadly margined with black, proximal margin and median are connected by a black transverse band before the middle of the cell. Colombia, Bolivia, Peru (Marcapata). *cuma*.

A. caunus *Cr.* (11 c) is velvety-black, only the first abdominal segment suffused by blue, the 5 last segments orange-yellow with a black dorsal spot on the first of them. Wings as in *cuma*. Expanse of wings: 38 mm. Surinam; Brazil (São Paulo). *caunus*.

A. xanthogastroides *Schaus* (11 d) resembles *Gymnelia xanthogastra* (11 i) by the colouring of the body and the very narrow black margins of the wings. Body black, the first abdominal rings are blue-spotted, the last ones orange. Forehips and spots on the shoulders are white. I obtained also numbers of the species from Argentina (Misiones), and it is possible that the *G. xanthogastra* reported from there is the present species. Paraná; São Paulo. *xanthogastroides*.

A. mathani *Rothsch.* (11 c). Head and palpi black, vertex and collar with metallic blue spots. Thorax black. The first abdominal ring is reddish-yellow, the following rings metallic blue with black transverse bands and median line; the last segment vermilion. The yellowish hyaline forewings exhibit a broad black apical spot; the basal half of the costal margin and an inner-marginal stripe are orange-yellow; at the cell-end a black median spot. The hindwings are less intensely yellow. From Colombia (Cundinamarca) in August. *mathani*.

A. completa *Wkr.* (11 d) differs from the following species by orange-red lateral bands at the hind-margin of the abdominal segments; behind the white ventral valve the venter is yellow-banded. Amazon (Pará); Peru (Marcapata). *completa*.

A. xenodorus *Druce* (11 d). Body black. On the vertex and collar metallic blue spots. The sides of the thorax below and the hips with white spots. The first abdominal ring exhibits above a broad white or yellow transverse band, the following rings subdorsal metallic blue spots, the last 3 segments are above curled in orange-red. Antennae black, before the tips white. Wings hyaline with broad black veins, discoidal spots and margins. From Mexico (Misantla; Tabasco) and Guatemala. *xenodorus*.

A. cincta *Schaus* is rather similar to the preceding, but much smaller and easily distinguishable by its ochreous-yellow ventral side. The first abdominal ring is yellow, the 3 last ones dark-red, the ventral valve white; instead of the subdorsal blue spots, the abdomen exhibits a dorsal row and on each side another row. Expanse of wings: 35 mm. French Guiana (St. Jean Maroni). *cincta*.

A. ectomelaena *Hmps.* (11 d). Body black, vertex, shoulders and thoracic sides white-spotted, the collar metallic blue spots; hips white. The first abdominal ring is above white with a black median line; the other segments exhibit dorsal and subdorsal rows of blue spots and sublateral rows of white spots; anal end orange. The hyaline wings exhibit extraordinarily broad, black margins, otherwise they are as in most of the species. Brazil (Sao Paulo). *ectomelaena*.

A. aroa *Schaus* (11 d) has a black body; on the vertex there is a blue spot; on the thorax white spots, forehips white. The abdomen exhibits on the dorsum and at the sides small, metallic-blue spots, between them at the sides red segmental indentations with the exception of the first segment, the anal end is scarlet; sublaterally there are white spots being united to a transverse band on the third segment on the ventral side; towards the anal end these spots turn reddish. The wings as in the other species. Venezuela (Aroa). *aroa*.

- suffumata*. **A. suffumata** *spec. nov.* (11 e) is a species very easily recognizable by the uncommonly great extent of the black colour. Body black; vertex, collar and the abdominal sides with metallic blue spots. The last abdominal segment and hind-margin of the penultimate segment brick-red; a sublateral row of yellow-red spots. Forehead, a spot below the collar and forehips white. The black forewings exhibit hyaline spots in and below the cell, between the middle radial and lower median vein, and a small, narrow spot lies between the upper radial and the lowest subcostal vein. The black hindwings are hyaline in the cell, behind and below it. Described according to 1 ♀ from East Colombia (Medina, 500 m, A. H. FASSL).
- laennus*. **A. laennus** *Wkr.* (11 e). Black, antennae at the tips white; on the shoulder a white spot. Vertex, collar and subdorsal spots on the 4 first abdominal rings metallic blue, the last 3 segments red, frequently with black dorsal spots. Wings hyaline with black veins, broad margins and discoidal spots; the middle spot of the hindwing is confluent with a triangular widening of the margin towards the proximal margin. Forehips in the ♀ black, in the ♂ like the large ventral valve white. From Brazil (Rio de Janeiro, Santos), very common.
- simplex*. **A. simplex** *Wkr.* (11 d) entirely resembles the following species, but the last 5 abdominal rings are red-margined and the last segment is quite orange-red, besides there are sublateral white spots. HAMPSON presumes in the species before us the ♀ of *collocata*. Amazon District (Pará).
- collocata*. **A. collocata** *Wkr.* (11 e). Head, thorax and abdomen are black; collar spotted in a metallic blue; spots on the shoulders, the hips at the sides of the metathorax are white. The abdomen shows subdorsal rows of metallic green spots; the last 2 segments are orange-curved. The ventral valve is white-margined and the 6th and 7th segments show on the ventral side a large, red-yellow spot. The wings as in the allies. From the Amazon District (Ega).
- whitelyi*. **A. whitelyi** *Druce* (11 e) from Peru has a black body; vertex and collar are blue-spotted; at the sides of the forehead, on the shoulders and thorax there are white dots; the forehips are white. The first abdominal ring is above yellowish-white, the other segments exhibit dorsal and lateral rows of blue spots, as well as lateral red articular indentations, the 4 middle segments besides sublateral white spots. The hyaline wings with very broad, black distal margins do not exhibit any peculiarities.
- serra*. **A. serra** *Schaus.* Head, thorax and abdomen black. Hind thorax and hips white-spotted; the abdomen shows lateral rows of metallic-blue spots, on the 4 middle segments between them carmine spots. Wings as in the allied species. Brazil (Rio de Janeiro).
- enagrus*. **A. enagrus** *Cr.* (11 e) is distinguished by the absence of every red colour. The black abdomen shows dorsal and subdorsal metallic blue-green macular stripes; shoulders and thoracic sides white-spotted, forehips white; vertex and collar are spotted in a bluish green. — f. **dexamene** *Druce* shows at the first abdominal ring lateral white spots. Surinam; Amazon (Ega; Sao Paulo).
- almon*. **A. almon** *Cr.* is unmistakable by the golden-green colouring of the abdomen; the body is black, on the collar green-spotted; the abdomen shows two very broad, golden-green subdorsal stripes beginning from the 3rd ring; also at the inner-marginal base of the forewing there is a green spot. The wings are hyaline with very broad black margins. Surinam. The species resembles the *Ixylasia semivitreata* figured on t. 11 e.
- simulans*. **A. simulans** *Druce* has quite black wings; on the forewings only the cell and a stripe below it are hyaline, on the hindwings the base. The body is black, the sides of the abdomen green and the base white. Expanse of wings: 40 mm. Cayenne.

15. Genus: **Sarosa** *Wkr.*

Exteriorly looking like *Cosmosoma*, distinguished by the woolly hairing of the thorax, in the veins there is no essential difference. Palpi erect. Single species also resemble *Isanthrene* from which, apart from the woolly thorax, they differ by the non-thickened antennae.

- ignicolor*. **S. ignicolor** *Mén.* (11 f). Head and thorax black-brown, shoulders pink-spotted; collar and shoulder-covers with white dots. The first abdominal ring is above pink, the 3 last ones orange-red, the others black-brown. The hyaline forewings are at the base pink, veins, margins, middle-spot and apical spot are black; on the hindwings the base and the submedian fold are likewise pink, the margin and apical spot black. The position of this species, not having been found again, remains uncertain. Expanse of wings: 42 mm. Described from Brazil (Minas Geraes).
- sesiiformis*. **S. sesiiiformis** *Wkr.* has like the preceding an entirely woolly haired abdomen. The body is black; spots on the forehead, thorax and first abdominal ring, as well as bands on the others are olive-yellow; thoracic sides and legs are spotted in a metallic blue, of the same colour are subdorsal and sublateral macular series at the abdomen; tarsi at the ends orange. The wings are hyaline with black margins, veins and internerval streaks in the marginal area. Expanse of wings: 40 mm. Venezuela.

S. xanthotarsis *Lathy* is closely allied to the preceding, but easily discernible by quite orange-coloured tarsi and proximal margin of the forewing, the veins being also orange-coloured towards the base. From Venezuela; may-be only a form of *sesiiformis*. *xanthotarsis*.

S. epona *Dogn.* is allied to the preceding, though it is smaller and differs by its more extensive yellow colouring; head and thorax are yellow; costal and proximal margins of the forewings are likewise yellow, so are the veins in the proximal half of the wing. Expanse of wings: 33 mm. Venezuela. *epona*.

S. xanthobasis *Druce* (11 f). This beautiful, large species has an orange-yellow thorax and abdomen. Head and collar black with metallic blue spots. The 3rd abdominal ring exhibits above a small, black spot which may also be absent, the 4th a triangular, small, black spot adjoining the last, black, metallic blue reflecting segments. Wings hyaline with black veins and margins, the base of the forewing is orange. Hitherto known only from Ecuador. *xanthobasis*.

S. connotata *Hmps.* (11 f) forms the connecting-link between the preceding species and the following *notata*; from the latter, to which it is very closely allied, it differs by the base of the wings being orange-yellow like in *xanthobasis*, furthermore by a large black spot on the metathorax and by the somewhat more extensive black colour of the abdomen; the triangular, black, metallic blue-pupilled dorsal spots have their points towards the head, their bases being directed analwards, what in *notata* is more or less distinctly just the contrary. Another mark of distinction is the very small lower half of the discocellular of the hindwing: in *notata* it is much larger, for which reason the veins 2 and 4 are much shorter petioled. Distributed from Venezuela (Merida) to Peru. *connotata*.

S. notata *Btlr.* (= *ufentina* *Druce*) (11 f) greatly resembles *connotata*, but immediately distinguishable by the black, not orange base of the forewing, the shoulder-covers being also black-margined. The abdomen exhibits above a more or less developed row of black, metallic-pupilled spots which may also be entirely absent: **innotata** *form. nov.* (= ab. 1 *Hmps.*) (11 f). The species occurs in Colombia, Bolivia, Peru, Ecuador und Venezuela (Merida), whilst *innotata* originates from Ecuador. *notata*. *innotata*.

S. acutior *Fldr.* (11 g) is smaller than the preceding and at once recognizable by the orange head. The first 4 abdominal rings are orange-yellow, black-margined, the 2nd segment exhibits a broader band with blue subdorsal spots in it; the last segments are black with small, subdorsal macular stripes. Wings yellowish hyaline with fine black veins and margins; the costal-marginal area orange, as well as the proximal margin and the apex of the hindwing. Ecuador, Amazon. *acutior*.

S. boenninghauseni *Rothsch.* (11 g) faintly resembles *Isanthrene basifera* (10 a) or *joda*. The body is black. Neck and thorax exhibit some orange hairs. At the abdomen steel-blue lateral spots, on the first segment above a yellow transverse-streak, the second and third exhibit yellow rings. The wings are yellowish hyaline, the costal margin, the cell-end and the basal inner-marginal half are orange; a subbasal spot above vein 1, the distal half of the proximal margin and the distal margin are grey-brown, a grey-brown, large spot lies at the anal angle of the hindwing. Described from Brazil (Rio de Janeiro). *boenninghauseni*.

S. klagesi *Rothsch.* (11 g). Black; the forehead is yellow-margined, vertex metallic violet-blue; collar and shoulder-covers at the base yellow-spotted. Abdomen dorsally and laterally with metallic violet-blue spots. Wings yellowish hyaline with black veins and margins, at the base of the forewing a metallic-blue spot; on the hindwings the black distal margin projects inwardly like a tooth near the proximal angle. The legs are black, the tibiae metallic blue with a black ring, the tarsi orange. Venezuela. *klagesi*.

S. helotes *Druce*. Head deep metallic blue; collar, thorax and abdomen brilliant orange, collar black-margined; the abdomen shows 3 rows of metallic blue spots, the last segment being black. Wings as in the following. Expanse of wings: 50 mm. Colombia. *helotes*.

S. ozora *Druce* (11 g) has a brownish-black body, posteriorly with a greenish reflection; antennae-tips and tarsi white. The 1st and 5th abdominal rings exhibit above orange bands, the latter also lateral spots. Wings hyaline with narrow black margins and veins, the forewings are greenish at the base and along the proximal margin. Expanse of wings: 44 mm. Colombia. *ozora*.

S. lutibasis *Hmps.* Body deep black; forehead, vertex, collar, metathorax, femora and tibiae blue-spotted; hind-hips yellowish-white. The abdomen exhibits on the first ring a yellowish-white basal spot and articular line, on the second ring sublateral yellowish-white spots, and on all the segments subdorsal, metallic blue spots. Wings yellowish hyaline with broad black margins and veins; at the base a blue spot; at the costal margin and above and beneath vein 1 orange stripes. Expanse of wings: 36 mm. Panama. *lutibasis*.

S. pompilina *Btlr.* (11 g) greatly resembles the preceding and *mora*, but it is not so jet-black, but more brown-black; shafts of the antennae above red. The blue-black abdomen shows a whitish basal spot, subdorsal, leaden-coloured stripes and white lateral spots. Wings yellowish hyaline, costal margin and base of the proximal margin striped in carmine. Panama; Ecuador; Brazil. *pompilina*.

mora. **S. mora** *Schaus* likewise greatly resembles *lutibasis*, differing by orange-red tips of the antennae, yellowish-white, distally blue-bordered spots on the collar, orange-yellow tarsi. The abdomen exhibits also sublateral blue spots. The wings are brownish hyaline, veins, distal margin and internerval stripes in the marginal area are black; base of the proximal margin, costal margin and transverse vein red-brown. Costa Rica (Sixola), Panama (Chiriqui).

meridensis. **S. meridensis** *Schaus*. Head and thorax black, with blue spots on head and collar. The 1st and 2nd ring of the blackish abdomen are yellow-banded, the other rings exhibit violet-blue lateral spots; at the 2nd ring there are yet yellow lateral spots and, as on the 2 following rings white sublateral spots. Legs black and blue striped, tarsi ochreous yellow, forelips opalescent. Forewings yellowish hyaline with black veins, margins and broad apex, subcostally and at the proximal margin light-brownish. Hindwing more whitish hyaline with a narrow black border and yellow costa. Antennae black, before the tips yellow. Expanse of wings: 35 mm. Merida (Venezuela).

16. Genus: **Dasy Sphinx** *Fldr.*

Siphon well-developed, palpi short, pointing straight forward the whole body is densely covered with woolly hair; stoutly built. Veins of the wings as in *Sarosa*.

mucescens. **D. mucescens** *Fldr.* (11 h) is one of the largest *Syntomidae* known, the whole body is thickly covered with black-brown hair being blue-green at the tips. Wings hyaline with fine black veins and distal margin; base, costal- and proximal margins and discal spot broad black, base with blue-green hair; proximal margin of the hindwing white. Expanse of the wings: 72 mm. Colombia (Bogotá).

volatilis. **D. volatilis** *Schaus*. Much smaller than the preceding, black; the neck shows 2 large, white spots, the abdomen 2 rows of white spots, above as well as sublaterally; legs white-spotted. Wings hyaline with black veins and fringes; in the marginal area between the veins there are broad whitish stripes; base, costal- and proximal margins orange; on the hindwing the proximal margin and a dot at the angle of the transverse vein are black. Expanse of wings: 40 mm. Costa Rica (Volcano Poas).

17. Genus: **Lasiosceles** *Hmps.*

The very peculiar species known so far stands rather isolated. The second palpal joint is long-haired and extends as far as the vertex, the third being moderately long. The male antennae are very short ctenodont, at the tips serrate-dentate. Thorax and base of abdomen thickly woolly-haired. The lower median vein of the forewing rises below the lower cell-angle, the middle radial above. On the hindwing both the median veins and the lowest radial stand on a common pedicle, also the subcostal vein is petioled with the upper radial. On the upper surface of the hindwings the whole marginal half and an area extending along the submedian fold towards the base is covered with rough scent-scales.

erythrozonata. **L. erythrozonata** *Hmps.* (11 h). Head and thorax are deep blackish-brown with a blue reflection. Thorax, anterior and middle hips and the greater part of all the femora are carmine. Legs otherwise black. The blue-black abdomen is above and at the sides banded in carmine. At the base of the first segment there are lateral, long, red hair-tufts. On the ventral side, between the 3rd and 4th segments, dense tufts of rather coarse whitish scent-hairs are protruding. The forewing is in the basal third and in the costal-marginal half velvety-black, otherwise greyish-brown. In the disk 4 hyaline spots beneath each other, the lowest being the smallest; behind the cell 4 similar hyaline spots. Hindwings black-brown with 2 hyaline spots behind the cell above and below the middle radial. The scent-scales are of a yellow-grey colour. — Before me are 2 male specimens, one from Panama (Chiriqui) from where the species was described, the other from Costa Rica (southern side of the volcano Irazu).

18. Genus: **Gymnelia** *Wkr.*

It contains mostly robust species with a stout, round abdomen. The thorax is woolly-haired, the wings are broad. The shafts of the antennae are not thickened, in contrast with the genus *Homoeocera* which is otherwise very much like it. On the forewing the upper subcostal vein rises freely from the cell, whilst on the hindwing the lower median vein and the lower radial rise from a common pedicle. We quote the 3 species *cocho*, *pitthea* and *chimaera*, which are otherwise reckoned to this genus, though they look very differently, in the genus *Pseudosphenoptera*, since *P. basalis* seems to be the ♀ of *pitthea*; both have several times been found in copula.

lyrcea. **G. lyrcea** *Druce* (11 g). Body orange-yellow, thorax marked in black. The abdomen is yellow with black rings which grow broader above on the 3rd to 5th segments and form spots being metallic blue-pupilled. Beginning from the 6th segment, the abdomen is quite black with metallic blue transverse bands. The hyaline

wings exhibit a black apical spot; costa of the forewings yellow; the inner-marginal part of the hindwings exhibits a black, lobular appendage. Ecuador.

G. peratea Dogn. (11 h) resembles *lyrcea*, but it is much larger. The body is orange-yellow as in *peratea*. *lyrcea*. The terminal joint of the palpus and the antennae are black; anterior half of the collar black; shoulder-covers at the base black-spotted and distally broadly margined by black. The orange-yellow abdomen is above metallic greenish-blue, beneath black-curved. The 3 last segments are in single specimens quite black and blue, among 6 specimens before me, however, only in one of them. The wings are hyaline, the apex black only between the 5th and 3rd subcostal veins; the proximal margin of the hindwing broadly black, at the proximal angle with long yellowish hair. Only from Colombia, where it is apparently not rare.

G. plumosa Rothsch. Body orange, on the thorax a black discal spot; the abdomen shows a series *plumosa*. of black, dorsal bands. Antennae strongly combed, brown. Wings yellowish hyaline, base and costal margin orange, distal margin grey-brown. Length of forewings: 17 mm. Colombia (Cañon del Tolima), in December. The species has remained unknown to me, it seems to resemble *Poec. vespoidea* (14 i).

G. latimarginata Hmps. (11 h) looks exteriorly exactly like an *Autochloris*. The body is black; thoracic *latimarginata*. sides and hips white-spotted; shoulder-covers orange-striped. First abdominal ring with a yellowish-white band being parted by a black dorsal spot; the other rings are blue-spotted on the sides of the dorsum, with orange-yellow segmental lines between, the last rings are also above provided with orange-red transverse bands increasing in width towards the anal end. The wings faintly yellowish hyaline, as in *Autochloris* with broad distal margins. Colombia (Bogotá).

G. taos Hmps. (11 h). The body is black; the forehead, vertex, collar, metathorax and legs are spotted *taos*. in a metallic blue; shoulder-covers orange-striped. Abdomen with subdorsal, metallic-blue spots and narrow orange-red transverse bands which grow somewhat broader above, resembling spots; on the ventral side sublateral blue macular series. The hyaline forewings are of a yellowish tinge towards the base, with a metallic-blue basal spot; a black apical spot. Colombia. — From Argentina a subspecies has been described: — f. *jujuyensis* *jujuyensis*. Jørgensen in which the yellow colouring is increased, as for instance the basal half of the palpi, the face between and below the antennae, the posterior margin of the eyes and pronotum, tibiae and tarsi, as well as the whole underside of the thorax and abdomen are ochreous-yellow; the sublateral blue spots are absent.

G. doncasteri Rothsch. (11 i) has an orange body, the third palpal joint is black, antennae black, on *doncasteri*. the head at the base of the antennae black spots, the base of the collar black, shoulder-covers and thorax black-striped. The abdomen is black-curved, on the 3 last segments subdorsal, metallic-blue spots. Wings hyaline with black fringes and apical spot; costa at the base yellowish, the basal half of the proximal margin broadly black with a yellow stripe; at the proximal margin of the hindwing a black, hairy, lobular appendage. Venezuela.

G. jordani Zerny (= *baroni* Rothsch. [praeocc.], *ottonis* Rothsch.) (11 i). Head black, on the forehead *jordani*. an orange spot; vertex and collar metallic-blue, black-bordered; shoulder-covers orange, distally black; thorax black. First abdominal ring reddish-yellow with a large spot, otherwise the abdomen is metallic steel-blue, with deep orange-red segmental indentations, which colour is expanded to a spot on the dorsum of each segment. Hips orange; femora black and metallic blue; tibiae orange, at the base metallic-blue, tarsi at the basal half orange, at the apex black. Antennae black. Wings faintly yellowish hyaline with black, narrow borders and a small apical spot. Ecuador; Peru.

G. gemmifera Wkr. (15 a) is a very conspicuous, large species; head and thorax are black, with metallic- *gemmifera*. blue spots and on the shoulder-covers with orange stripes, thorax and legs orange-haired. The black abdomen, being orange-haired at the base, shows subdorsal rows of very large, crescentiform, metallic-green, transverse spots. The wings are yellow hyaline with black veins and margins, the discal spot and a spot at the base of the forewing being metallic-blue. Expanse of wings: 54 mm. Venezuela.

G. boettgeri Rothsch. (11 i) is a small, insignificant species with a unicolorously greenish-olive body, *boettgeri*. only the thorax being orange; antennae black, legs blackish olive. The wings are faintly yellowish hyaline, the base of the forewing and the inner-marginal area of the hindwing olive; the proximal half of the hindwing is covered with thick, long hairs. Peru (Huancabamba).

G. plagiata Rothsch. Body black; legs, underside and antennae more brownish; thorax and a large *plagiata*. spot in the basal half of the abdomen both above and beneath pale reddish-yellow. Wings reddish-yellow transparent with black veins and margins. Expanse of wings: 25 mm. Peru (Carabaya), in April.

G. ockendeni Rothsch. (11 i) is a small species from Peru with a black body. The abdomen shows *ockendeni*. on the second and third segment carmine lateral spots, on the same rings sublateral white spots; the last segment is beneath spotted carmine. The legs are black, the forehips and tibiae carmine. The hyaline wings show a broad black basal part and black margins.

- tarsipuncta.* **G. tarsipuncta** Schaus. Body black; ends of antennae and spots on the legs white. Shoulders and upperside of the first abdominal segment red. Wings hyaline, veins, costal- and distal margins narrowly black; on the forewings more than one third of the base is black, the discocellular and apical spot; on the hindwing the base and the proximal margin are black. Expanse of wings: 41 mm. Brazil (Sa. Catharina).
- xanthogastra.* **G. xanthogastra** Perty (11 i) resembles a species of the humble-bees: anterior body deep velvety black with metallic-blue spots on the vertex, legs, and subdorsal spots on the 3rd abdominal segment (which are absent in the ♀), beginning from which the abdomen is rufous-orange. Forehead and forehips in the ♂ white. The wings are entirely hyaline with fine black borders and veins, at the base of the forewing is a metallic-blue, small spot. This beautiful species occurs in Brazil, furthermore it is reported from Paraguay and Argentina; it is met with almost during the whole year, the most frequently in October—December and March—May on the most various compositae. The habitat Argentina may possibly refer to *Autochloris xanthogastroides* Schaus.
- paranapanema.* **G. paranapanema** Dogn. greatly resembles the preceding, differs, however, by its black forehead and the abdomen the first 3 rings of which are entirely black and the 4th partly black; on the other orange-red rings there are subdorsal black spots being blue-iridescent on the first rings. Wings as in *xanthogastra* (11 i). Expanse of wings: 43 to 44 mm. Brazil (São Paulo).
- torquata.* **G. torquata** Druce (11 i) is one of the largest species; entirely black, only the posterior half of the abdomen, beginning from the fourth segment, is scarlet; ventral valve and a median stripe beneath brown-black; on the forehead 2 white dots, antennae at the tips white. On the hyaline wings the basal third is black, veins and margins, on the forewing the discal and apical spots broadly black. From Brazil (Rio de Janeiro).
- baroni.* **G. baroni** Rothsch. (11 i) resembles *Homococera duronia* and has a black body covered with thick woolly hair; at the base of the antennae two white dots, antennae steel-green; the distal half of the collar is brick-red. The abdominal rings 1, 5, 6 and 7 show 2 brick-red, subdorsal spots each. The first two pair of legs are black, at the joints white-banded, the hindlegs black with white tarsi and spurs. The wings are golden-yellow hyaline, the costal margin steel-green, at the base with a brick-red spot, at the proximal margin an orange-red stripe; veins, discoidal spot, distal margins and apical spot broadly black. Ecuador.
- pilosa.* **G. pilosa** Rothsch. (11 k) is a most peculiar, unmistakable animal. The body is black with a metallic-green reflection, particularly on the abdomen. The collar exhibits laterally a white spot; the shoulder-covers are long white haired at the distal margin and apex; the second and the 4th to 7th abdominal rings exhibit above one orange-red transverse band each, the fourth and fifth sublateral orange spots. On the dorsum, in the middle of the orange bands, there are tufts of loose, white hairs; the same white hair-tufts are at the sides and on the ventral side. The antennae are black with white tips; legs black, at the joints white-spotted, hips long and vastly white-haired. The hyaline wings are quite faintly coloured yellowish, at the base greenish-black with a white spot. The proximal margin is in the basal half black, then whitish; between the vein 1 and the submedian fold a yellow, long spot. Between the middle radial and the lowest subcostal vein the distal margin is rather strongly drawn in, so that the apex becomes somewhat sickle-shaped; both the upper radial veins are distally brought very much nearer. The discoidal spot and subapical spot which is the broadest between the upper and middle radial vein, are black. The hyaline hindwings are in the innermarginal halves whitish, with long white hair; on the lower median vein and between the two upper radials, the black distal margin is strongly drawn in; the discoidal spot is black. Before me from Peru (Marcapata). Only ♀♀ are known hitherto, possibly belonging to the following of which I only know ♂♂.
- buckleyi.* **G. buckleyi** Druce (11 k). Black; tips of the antennae, ends of the tibiae, and tarsi white; abdomen with a green reflection, on the first ring with 2 orange-red dorsal spots, on the 4th with lateral and sublateral bands, the 5th and 6th with orange lateral spots. Wings hyaline with black veins, basal area broadly black with a white dot; proximal margin, a large, square discal spot, apical spot with an undulate proximal bordering and a marginal spot below the lower median vein black. Expanse of wings: 46 mm. Ecuador.
- flavicornis.* **G. flavicornis** Druce (11 k). Head and thorax black, antennae orange-yellow, abdomen blue-black. Wings black with a blue reflection and hyaline spots: 2 in the cell-end, a large, wedge-shaped one below them and a stripe above the inner-marginal vein, 3 spots behind the cell between the lower median vein and the middle radial, as well as oblong spots above and below the upper radial vein. Hindwing with an oblong spot below the cell, a spot between the lower median vein and the lower radial, and 2 oblong spots behind the cell. Expanse of wings: 54 mm. Ecuador.
- herodes.* **G. herodes** Druce (11 k). Head and thorax black; tips of the antennae and 1st joint of the tarsi white; abdomen metallic greenish. Wings black with a blue reflection; costal margin of the forewing greenish; between the penultimate subcostal vein and the upper median vein there is in the marginal area a large hyaline spot with an irregular proximal bordering, traversed by black veins. Expanse of wings: 38 mm. Ecuador.

19. Genus: **Mallodeta** Bllr.

5 species of medium size, recognizable by the abdomen being very slender at the base and provided with short hair-tufts on the last 4 segments. The neurulation is the same as in *Cosmosoma*.

M. sanguipuncta Druce (14 k) is a very imposing species from Ecuador. The body is black; the antennae are white at the tips; shoulder-covers striped carmine; collar in some specimens with white dots; forehips white-spotted; the femoral end, tibiae and tarsi white. The first abdominal ring shows above two white dots, the first and third segments subdorsal carmine spots; from the 3rd to 7th segments the abdomen is dorsally, laterally and sublaterally white-dotted. The hyaline forewings exhibit a broad black base and apical spot. On the underside the base of the wings is carmine. *sanguipuncta.*

M. sortita Wkr. (= *deyrollei* H.-Schäff., *alecyra* H.-Schäff.) (12 a) resembles the following species, *sortita.* but it has no orange spots on the abdomen and besides the dorsal white spots are absent on the first segments, only on the last ones there are such, the lateral ones, however, are present. The forewing exhibits at the inner margin two strong orange stripes. Brazil (Rio de Janeiro, Sa. Catharina).

M. consors Wkr. (= *norma* H.-Schäff.) (12 a). Black with minute white spots on the vertex, shoulders and abdomen, the spots of the two last abdominal rings are larger; the second, strangulated segment shows a pair of subdorsal, orange-yellow spots. Wings faintly yellowish hyaline, orange at the costal margin and base of the inner margin, the distal margin being narrowly black. Brazil. *consors.*

M. clavata Wkr. (12 a) has a quite unicolorously black body. The wings are hyaline, the distal margin narrowly black. In the subcostal area there are traces of orange-yellow colouring. Brazil. *clavata.*

M. parthenii F. (= *multicincta* Wkr.) (12 a) has shorter palpi than the other species, with quite a short terminal joint; the ♂ bears a ventral valve at the 1st segment, being absent in the other species. The black body, being finely white-curlled and laterally red-spotted, makes the species easily recognizable; collar and shoulder-covers are white-bordered and red-spotted, the first abdominal ring subdorsally red-spotted; the ventral side is white. The wings are hyaline with black veins, margins and apical spot; the discal spot exhibits a metallic-blue line. Hayti. *parthenii.*

20. Genus: **Phoenicoprocta** Hmps.

About 20 medium-sized species with frequently very black marked forewings. The abdomen is mostly magnificently yellow and red and besides decorated with blue metallic spots and exhibits hair-tufts at the last segment. The lower median vein rises on the forewings at a great distance from the cell-angle. On the hindwings the cell is not visible owing to the oblique course of the discocellular.

P. chrysorrhoea Hmps. (12 a). Body black, on the forehead, vertex and collar with metallic-blue spots; the abdomen exhibits on the first segment above a blue spot and subdorsally orange spots, the anal tuft being orange; forehips white and carmine. Wings hyaline with black veins and moderately broad margins, a broad black apical spot of the forewings. Expanse of wings: 34 mm. Colombia (Bogotá). *chrysorrhoea.*

P. flavipicta Hmps. differs from the preceding by its more brownish colour of the body, yellow shoulder-covers and similar spots on the collar, white forehips, yellow middle- and hind-hips, yellow transverse bands from the 2nd to the last abdominal ring and yellow, white-margined ventral valve. British Guiana. *flavipicta.*

P. metachrysea Druce (12 a). Head, thorax and abdomen are black, forehead and shoulder-covers spotted in a metallic blue. The abdomen exhibits dorsal and subdorsal rows of silvery-blue spots. From the 3rd segment there begin orange-yellow subdorsal spots increasing in width towards the last segments, in order to touch each other above on the penultimate segment; anal bush orange. Ventral valve and the last segment but one also beneath with orange spots. Forehips white. The hyaline wings exhibit rather broad black margins, at the base of the wings a blue spot. Described from Cayenne. *metachrysea.*

P. vacillans Wkr. (12 a) has a black body with a carmine anal tuft, spots on the forehead, vertex, collar, shoulder-covers and thorax are metallic blue, dorsal and lateral spots at the abdomen are more silvery greenish-blue; forehips white and red. The hyaline wings exhibit broad black margins. Occurring from Venezuela to Bolivia. — **auriflua** form. nov. (12 b) may be the name of the subspecies sometimes flying among the typical form, in which the anal tuft is of an ochreous-yellow to orange tinge. — In another form: **punicea** Strand (= ab. *punicea*. 1 Hmps.) beside the anal tuft also the last 3 or 4 segments are carmine. In the form: **nigropeltata** Strand from Trinidad the ventral valve is black with a white hind-margin. *vacillans.*

P. analis Schrottkey (= *nigrivalvata* Dogn.) (12 b) greatly approximates the form *incandescens* of the preceding species, from which it differs by the orange-yellow colour of the 3 last abdominal segments, quite white forehips without any lateral red, and an entirely black ventral valve. Described from Paraguay, before me also from Peru (Pachitea), and reported from Argentina (Misiones). *analis.*

- haemorrhoidalis*. **P. haemorrhoidalis** *F.* (= *frontalis* *Wkr.*) (12 b) from Brazil has an entirely black body; the forehead and vertex are covered with metallic-blue scales, the anal tuft is interspersed with red. The wings are hyaline with black-grey veins and margins. A discoidal spot and the apex of the forewing are black.
- baeri*. **P. baeri** *Rothsch.* (12 b). Head and collar metallic-blue; palpi black; antennae black with white tips; thorax and abdomen black with a metallic-blue median line; the penultimate segment exhibits an isabel-yellow band, the anal tuft is black and carmine, forehips white, at the base red-spotted. On the black forewings the basal two thirds of the discocellular and a spot below it are hyaline. Hindwings hyaline with broad black margins. Brazil (Rio Uruhu, Goyaz).
- steinbachi*. **P. steinbachi** *Rothsch.* (12 b). Head and collar metallic lustrous greenish-blue, shoulder-covers and thorax black with greenish-blue stripes; the abdomen is black, above with a series of small, pale grey spots; anal tuft carmine. Palpi black, antennae black with white tips. Forehips and posterior tarsi white, the other parts of the legs are black. The wings are hyaline with broad black margins, the forewings have a large, black discoidal spot. East Bolivia.
- sanguinea*. **P. sanguinea** *Wkr.* (15 a) has a black body; head and forehead blue-spotted; collar blue, bordered by carmine; shoulder-covers carmine; the abdomen exhibits subdorsal, carmine macular stripes and a similar anal tuft, on the 1st ring metallic-blue spots, on the others green-silvery, dorsal and subdorsal spots; hips carmine, forehips above white. Wings as in the allies. Expanse of wings: 32 mm. Honduras.
- trinitatis*. **P. trinitatis** *Strand* greatly resembles the preceding, but on the forewings the upper median vein rises farther in front of the cell-angle; collar blue with a black margin, shoulder-covers in the basal half blue-scaled, thorax above with a blue, black-margined median longitudinal band; forehead one-coloured blue; hips inside white, at the apices outside reddish; palpi shorter. Expanse of wings: 31 mm. Trinidad (Caparo).
- lydia*. **P. lydia** *Druce* (12 b). Head black with a blue forehead. Palpi and antennae black, the latter with white tips. Collar and shoulder-covers orange with black margins. Middle part of the thorax metallic blue. Legs black, forehips laterally scarlet, anteriorly silvery white. Abdomen orange, towards the anal end and beneath scarlet. On the 1st segment laterally a metallic blue spot, on the 2 or 3 next ones silvery green spots. On the dorsum metallic greenish-blue spots with black margins growing smaller or disappearing altogether, towards the middle growing very large again on the 2 or 3 last rings. Forewings black with hyaline streaks in the cell and 2 below it, 5 behind the cell. Hindwings hyaline with black veins and margins. From Mexico (Orizaba; Tabasco).
- chamboni*. **P. chamboni** *Dogn.* greatly approximates the preceding from which it differs by the following marks: behind the cell on the forewing there are only 4 hyaline spots, the one between the median veins being absent. The first palpal joint with orange-red hair; antennae before the tips white-spotted, the tips black; thorax quite black, with blue spots; abdomen above bluish-black, on the first 5 segments orange-yellow subdorsal spots, anal hairing carmine, ventral valve quite black, the other part of the venter carmine-pink, the last rings black with a blue reflection. San Salvador.
- rubiventer*. **P. rubiventer** *Hmps.* (= *sanguinea* *Druce*) (12 c) is well-marked by red subdorsal macular series running through to the red anal tuft, and an entirely red underside of the abdomen. Panama.
- astrifera*. **P. astrifera** *Btlr.* (12 c). The body is black with a red anal tuft and red subdorsal streaks only on the first 4 abdominal rings, whereby it differs from the preceding; also the ventral valve in the ♂ is red-margined, otherwise the venter is black. Metallic-blue spots are on the forehead, vertex and thorax, the collar being blue, bordered by orange as the shoulder-covers. The abdomen exhibits metallic-blue spots on the dorsum and the sides of the first segment, green-silvery dorsal and lateral spots on the rest of the abdomen. The hyaline wings are very broadly margined by black. From the Amazon (Porto Alegre).
- ignicauda*. **P. ignicauda** *spec. nov.* (12 c) is very closely allied to the two preceding species; it is easily discernible by red subdorsal streaks being only to be seen on the first abdominal ring, as well as by the 4 last abdominal rings being above and beneath entirely red, the two first of which exhibit black and metallic-blue dorsal spots; Collar and shoulder-covers are quite black. All the rest like in the preceding. A ♂ from Cuyaba, Province of Matto Grosso (BANG-HAAS).
- cubana*. **P. cubana** *Druce*. Head and thorax black with small blue spots; neck and collar orange. The abdomen is above in the larger proximal half orange, the rest, as well as the sides and venter carmine. Above the segments are bordered by metallic blue. Forehips white. On the hyaline forewings the veins and margins, as well as broad apical spots black, strewn with silvery blue scales. Also the hyaline hindwings are broadly bordered by black, at the inner margin carmine. Expanse of wings: 28 mm. Described from Cuba.
- eximia*. **P. eximia** *H.-Schäff.* (12 c) has a black body with a metallic-blue reflection; collar and shoulder-covers oranges. On the first abdominal ring there are small subdorsal red spots; the four middle segments exhibit sublateral white dots. The forewings are black with single metallic-blue scales; below the base of the cell is an elliptic hyaline spot, a spot in and below the middle of the cell, and 5 oblong spots between the lower median vein and the lowest subcostal. Hindwings hyaline with a broad black margin. Under surface

of the wings with metallic-blue spots. — The extent of the black colour varies, sometimes there are preponderantly hyaline spots, so that the black discoidal spot is separated from the inner-margin: f. *portoricensis* *form. nov.* *portoricensis*. (= ab. 1 *Hmps.*) from Porto Rico, sometimes the hyaline spots are still more reduced: — f. *reducta* *form. nov.* *reducta*. (= ab. 2 *Hmps.*) occurring in St. Cruz. The type of the species flies in Cuba.

P. *thera* *Druce* (12 c) is black, on the forehead, collar, and laterally and dorsally on the abdomen *thera*. with blue spots; spots on the shoulder-covers, as well as subdorsal spots on the first abdominal segment are orange; forehips and ventral side carmine. The wings are similar to those of the following species. From Mexico (Tabasco).

P. *mexicana* *Wkr.* (12 c). Head, thorax and base of the abdomen deep velvety black, abdomen orange-yellow, analwards warming into scarlet, with black segmental indentations. Wings as in *lydia*. Legs scarlet with black tarsi. Ventral valve in the ♂ black. The species is common in Mexico (Orizaba; Jalapa). *mexicana*.

P. *teda* *Wkr.* (12 c) is one of the smallest species: the body is black-brown with carmine spots *teda*. at the base of the palpi, at the shoulder-covers, as well as lateral spots along the abdomen. The first abdominal ring exhibits laterally a white spot, the ventral valve in the ♂ and the first abdominal rings on the ventral side being white. The wings are hyaline with broad, brown-black margins, the forewings exhibit yet a median band and at the base a carmine spot. From Brazil (Sa. Catharina, São Paulo).

21. Genus: **Eunomia** *Hbn.*

Above all distinguished by the antennae being thickened shortly before the tips, whereby they resemble certain *zygaenidae*; they are besides doubly ctenodont in the ♂. The abdomen is rather short and broad and the first segment exhibits on both sides a vesicle above which, subdorsally, there are yet tubercles. The wings are rather broad without any important particularities of the neurulation; on the hindwing the subcostal vein is short petioled with the uppermost radial. The species on the whole inhabit certain groups of islands.

E. *colombina* *F.* (= *fasciatella* *Mén.*) (12 d). Similar as the following, somewhat smaller, with broader *colombina*. wings; the venter is also beneath black, white-curved with a middle row of red spots; the abdomen shows on the first ring dorsal and lateral red spots, the 3rd segment a red ring; ventral valve red. Hayti; Honduras; Brazil.

E. *rubripunctata* *Btlr.* (12 d) resembles the preceding species, but it is larger, with more stretched *rubripunctata*. wings, and differing by the entirely red underside of the abdomen. Head and thorax are black, the first palpal joint, vertex and anterior half of the collar carmine; collar and shoulder-covers with fine white margins. The carmine abdomen is only on the dorsum black with numerous fine white transverse lines. Forewings hyaline with a red, discoidal spot being bordered by black. The margins and a large apical spot are black, the veins in them finely marked in white. The distal margin expands somewhat also below the lower median vein, in which there is some carmine scaling. The species flies in Jamaica.

E. *latenigra* *Btlr.* (12 d) has a black body; the first joint of the palpus, as well as a stripe at the second *latenigra*. joint, a line on the forehead, the anterior half of the collar, as well as the underside of the thorax are carmine; the shoulder-covers are bordered by white. The abdomen, except the last segments, is beneath and on the sides carmine; on the last segments short white dorsal streaks. The hyaline wings exhibit broad black margins, being expanded to large spots in the apical halves. From the Bahama-Islands, occurring also in Honduras.

E. *nitidula* *H.-Schäff.* is the smallest species, with 3 pair of red spots on the thoracic sides; the first *nitidula*. abdominal ring is carmine, the others black with 2 fine white rings each. Venter carmine. Expanse of wings: 26 mm. Cuba.

E. *caymanensis* *Hmps.* Body black, white-striped, collar and shoulder-covers bordered with white. *caymanensis*. Thorax, sides of the forehips and the femora above carmine except the ends, for the rest the legs are white-striped, the anterior side of the hips white. The black abdomen shows series of subdorsal white and carmine streaks, on the posterior segments above white articular lines, the last segment being white-spotted, with lateral red stripes, the venter at the base carmine, for the rest red-banded. Wings as in the other species, the black marginal colour dusted with white. Expanse of wings: 32 mm. Grand-Cayman near Cuba.

E. *insularis* *Grote* (= *elegantula* *H.-Schäff.*) differs from the preceding by its much smaller size, entirely *insularis*. white forehips, whereas the thorax, middle and hind-hips and the distal part of the hind legs are carmine. The abdomen is black with white segmental lines which are broader on the 2nd and 4th rings; the 1st ring shows a white median spot, all the other rings red dorsal and lateral spots. Venter at the base carmine, in the ♂ with white stripes. Cuba.

22. Genus: **Pheia** *Wkr.*

Mostly small butterflies the exterior of which resembles that of the *Cosmosoma*-species, with hyaline wings. Antennae with comb-like or saw-like teeth, the palpi extending beyond the vertex are erect. Distinguished by the discocellular of the hindwing running so obliquely that the cell is not visible at all in the butterfly being

normally distended, but is entirely covered by the inner margin of the forewing; the lower median vein and lower radial are standing on a long footstalk, the upper median vein and middle radial are absent, and the upper radial vein and the subcostal rise in common from the upper cell-end. On the forewing the middle radial vein, in contrast with *Loxophlebia*, rises from the lower cell-angle.

- elegans*. **Ph. elegans** Druce (= *drucei* Kirby, *cingla* Schaus) (12 d). Wings faintly yellowish hyaline, veins and margins black; the black border of the distal margin grows particularly broader at the apex of the forewing and projects somewhat inward on the lower median vein. A costal stripe as far as the apical spot, and spots at the base of the inner margin and vein 1 are orange-yellow. The palpi being yellow at the base are black. The forehead covered with white hair, vertex black with metallic-blue scales. Collar and shoulder-covers orange-yellow margined by black, metathorax with a large, metallic-blue spot. Abdomen orange-yellow, the 3 last segments black, triangular black dorsal spots with metallic-blue scales, blue subdorsal spots on the 2nd and 3rd segments. Legs yellow and black, antennae black. Mexico, Guatemala, Costa Rica, Panama, Venezuela.
- costalis*. **Ph. costalis** Rothsch. (12 d) distantly resembles *Ph. elegans*, but it is much smaller and neater, of a more slender structure. Body orange; the forehead is silvery white, palpi and antennae black; thorax black-spotted; abdomen above with a series of black median spots, the last two segments quite black with blue-grey spots. The wings are hyaline, at the base and four fifths of the costal margin orange, as well as at the inner margin; margins and apical spots for the rest black; the inner-marginal area of the hindwing black with orange-yellow hair. From Bolivia, taken at an altitude of 1000 m.
- gaudens*. **Ph. gaudens** Wkr. (12 d) likewise resembles *elegans*, but it has an orange-yellow head, with a black vertex spotted in a metallic green. The orange-yellow abdomen exhibits black transverse bands which are dorsally expanded to triangular spots and exhibit dorsal and lateral, large, metallic-green spots. Hips and abdominal end beneath yellow, in *elegans* black. Venezuela, Amazon (Pará), Peru.
- flavicineta*. **Ph. flavicineta** Dogn. (26 k). Body black; palpi yellow with a black terminal joint, collar orange-yellow, a transverse streak between the antennae and shoulder-covers with single, whitish hairs; metathorax with an orange-yellow transverse band. The abdominal rings show above small white dorsal spots; the first rings exhibit a yellow lateral band, the following ones an orange lateral spot each; venter black, with yellow-white rings, ventral valve yellow. Hindlegs quite yellow, the forelegs black and yellow. At the base of the hyaline forewing is a white spot, costa yellow. Argentina (Tucuman).
- xanthozona*. **Ph. xanthozona** Dogn. (12 c), a very small, insignificant species from French Guiana, has a black-brown body. The forehead is white; collar and shoulder-covers orange, bordered by black. The 3 first abdominal rings are above and on the sides orange-yellow, beneath white. Hips white. The wings are hyaline, in an oblique exposure to light strongly iridescent, with black veins and margins; median and apical spots of the forewing very extensive. The specimen before me was taken in February.
- sperans*. **Ph. sperans** Wkr. (12 e) is one of the largest species; the body is black; forehead and vertex blue-spotted, on the collar, shoulders, meso- and metathorax there are white and blue spots; on the shoulder-covers indistinct orange spots. The abdomen exhibits dorsally, laterally and ventrally stripes of silvery-green spots. The wings are hyaline with broad black veins and margins; on the forewing a large black median and apical spot. Colombia; Amazon-District.
- haematosticta*. **Ph. haematosticta** Jones (12 d) has a black-brown body. Thorax and forehips white-spotted, middle and hindhips entirely white. Collar and shoulders red-spotted. The 3 first abdominal segments on the ventral side white. Antennae black, only beneath near the tips white. The hyaline wings are rather broadly margined by black; in the black base of the forewing there is an elliptic red spot; apical spot extraordinarily broad. South Brazil (Paraná; Santos).
- pyrama*. **Ph. pyrama** Dogn. (12 d) is a small insignificant species with a black body. On the forehead two white spots, the base of the shoulder-covers red, also in the posterior half of the collar there are single, interspersed, red scales. Hips and underside of the first abdominal rings in the ♂ white, in the ♀ black. The hyaline wings have black veins and broad black margins, very extensive discoidal and apical spots. French Guiana, March and September.
- haemapera*. **Ph. haemapera** Schaus (12 e) from Brazil (Sa. Catharina) is a smaller species with a deep velvety-black body, only the collar and the extremest end of the abdomen exhibit carmine spots. Wings hyaline with broad black margins and discoidal spots. The hips and the ventral side of the first abdominal rings are yellowish-white.
- discophora*. **Ph. discophora** Dogn. is a small species with an expanse of the wings of 24 mm; body black, on the shoulder-covers, thorax and first abdominal ring orange-spotted; narrow angular indentations on the other rings and the ventral side are orange-yellow; tarsi orange-striped, the posterior ones quite orange. The hyaline wings are distinguished by a very large black, orange-dusted discal spot; subcostal orange. Colombia.

Ph. regesta *sp. nov.* (12 e) is allied to *daphaena*. Body black-brown. Collar vermilion, bordered by *regesta*. black; on the shoulders a small indistinct red spot, shoulder-covers red-striped. The abdomen exhibits small dorsal and subdorsal spots of very sparse metallic blue-green scales which are somewhat more prominent towards the anal end. Antennae shortly before the tips white. The wings are hyaline and strongly iridescent; margins black-brown. Median spot very large, almost circular; apical spot very extensive; also on the lower median vein the distal margin projects far inward. 1 ♀ from Cuyaba, Province of Matto Grosso (BANG-HAAS).

Ph. daphaena *Hmps.* (12 e) has a black body; forehead and vertex are white-spotted; collar, shoulders *daphaena*. and shoulder-covers with large carmine spots. The abdomen exhibits on the first segment 2 white dorsal spots, on the following segments metallic-green subdorsal spots, which are more and more laterally placed towards the anal end; the 2 first rings on the ventral side white. The hyaline forewings are broadly striped carmine at the costal and inner margin; distal margins, median and apical spots black. Flying in Dominica and Santa Lucia.

Ph. utica *Druce* (12 e). The absent red subcostal stripes of the forewings easily distinguish the species *utica*. from *daphaena* which it otherwise resembles very much; the abdomen shows above likewise 2 large white streak-like spots, the metallic-green colour, however, is altogether absent. Expanse of wings: 26 mm. Mexico (Guerrero).

Ph. lateralis *Klages* is allied to the preceding, from which it is easily distinguished by broad, carmine *lateralis*. subdorsal stripes on the abdomen, which suddenly grow narrower beginning from the 6th segment, being also placed more laterally and turning more orange. The 3 first rings exhibit a broad white ventral stripe. The abdomen exhibits above yet 2 rows of golden-green spots. Venezuela.

Ph. sandix *sp. nov.* (12 e) is very nearly allied to the preceding species and is exteriorly easily discernible *sandix*. by the orange, not carmine colour. The head is black-brown, in the neck 2 small white spots. Collar, shoulders, shoulder-covers and thorax orange; shoulder-covers distally black-margined, on the pronotum 2 round black spots. Abdomen black-brown; the first segment exhibits 2 yellowish-white subdorsal longitudinal spots, the other rings small, metallic-blue, subdorsal spots, as well as broad, orange lateral stripes; on the 2nd and 3rd segments this stripe extends as far as the ventral side. Antennae black with white tips; legs black-brown, median tarsi white. The wings are hyaline, at the base, the costal and proximal margins broad orange, finely bordered by black; a square median spot, the distal margin, apical spot and a spot below the lower median vein are brownish black. 1 ♀ from Cuyaba (BANG-HAAS).

Ph. albisigna *Wkr.* (12 f) is one of the larger species of quite black-brown colour of the body; on the *albisigna*. neck and mesothorax small white spots; on the collar and shoulder-covers carmine dots. The abdomen exhibits on the first ring above a large, square, yellowish-white spot; the 2nd and 3rd segments are laterally yellowish, beneath white; forehips and spots at the sides of the thorax white. Wings hyaline with black margins, discoidal and apical spots. Widely distributed and not rare from Honduras, Venezuela, Guiana, the Amazon District.

Ph. bisigna *Kaye* is easily discernible from the preceding by its smaller size and two white spots *bisigna*. above on each of the first two abdominal rings; on the shoulder-covers large, carmine spots, collar quite black. Expanse of wings: 27 mm. British Guiana. May be a *Loxophlebia* and identical with *klagesi* which would then become synonymous.

23. Genus: **Loxophlebia** *Btlr.*

Like *Pheia*, but the middle radial vein of the forewing rises distinctly above the cell-angle. By this distinctive mark it also greatly resembles the genus *Mesothen* from which it is discernible by the non-angled, very obliquely running discocellular of the hindwing.

L. picta *Wkr.* (12 f). This pretty, small species is easily recognizable. The head is black, forehead *picta*. and tips of antennae are white. Thorax and abdomen are orange-red with a black, blue-spotted median stripe; the first abdominal ring exhibits silvery-white subdorsal spots; the 2 last segments are quite blue-black. On the hyaline wings are of orange-yellow colour: the base, a subcostal stripe, the lowest subcostal, the radial veins and the upper median vein and a spot at the distal margin below the upper median vein, on the hindwings all the veins and the basal half of the inner margin are yellow. Distributed from Guiana to the Amazon (Pará).

L. flavipicta *Schaus.* Head and palpi black with a white forehead. Thorax and abdomen orange- *flavipicta*. yellow; a large median spot on the abdomen, as well as the 2 last rings black with metallic scales. Legs yellow, tibiae and tarsi partly brown. The wings are hyaline; the base is yellow, behind it at the proximal margin there is a black spot and at the costal margin a black stripe as far as the transverse vein which is broadly black; at the inner-angle there is a black spot, and the apex is broadly black. The costal margin behind the middle, the distal margin between the lower median vein and the lower radial, the inner-margin in the middle, the radial veins and the upper median vein are yellow, the median and the lower median vein are black. On the hindwing the apical part of the distal margin, a stripe at the anal angle, and the base of the lower median vein are black, all the rest yellow. Expanse of the wings: 20 mm. Costa Rica (Sixola).

- broteas*. **L. broteas** *Schaus* (12 e). The head is black, forehead white, proboscis and palpal base orange; the black antennae have white tips. Collar and shoulder-covers are carmine, thorax black. The black abdomen exhibits on the 1st ring subdorsal white spots and lateral carmine macular stripes not reaching the abdominal end. Ventral valve orange. Hips, tibiae orange except the base and tarsi. The wings are hyaline, the broad distal margins black. A subcostal stripe orange; the veins are behind the cell orange coloured. Brazil (Sa. Catharina).
- splendens*. **L. splendens** *Möschl.* (12 f). Black; palpal base and proboscis orange, forehead white; collar narrowly bordered by orange, shoulder-covers orange; abdomen with orange stripes not extending as far as the end; the first segment exhibits dorsally two white dots. Ventral valve orange. Hips and tarsi yellow and white. The wings are hyaline with an orange-yellow basal spot; margins, median and apical spots black; the veins behind the cell partly orange-yellow, the same on the hindwings. Cayenne.
- cinctata*. **L. cinctata** *Hmps.* Head black with a white forehead; front side of the palpi, the basal joints of the antennae and neck yellow; thorax yellow, the larger half of the shoulder-covers and a broad dorsal stripe black; abdomen likewise yellow with a black median stripe, on the 2nd and 3rd rings black bands, the 3 last segments blue-black. On the hyaline forewings the base, a costal stripe and the radial veins are yellow, the other veins, margins, the apical spot and transverse vein black; also on the hindwings the base and the veins between the cell and margin are yellow. Expanse of wings: 28 mm. Venezuela.
- aurantiaca*. **L. aurantiaca** *Jones.* Head, palpi and antennae are black; hips white; collar, thorax and abdomen orange; a black median line on the thorax and the 2 first abdominal rings; the 3 last segments black. The wings hyaline, narrowly bordered by black-brown, broadly at the apex; base orange, on the cell-fold in the marginal area a black stripe. Expanse of wings: 23 mm. South East Brazil.
- egregia*. **L. egregia** *Schaus.* Head black, forehead white, as well as a spot on the vertex. Body red, middle of the thorax and the dorsum of the 3 first segments and the whole last segment black. Hips and inner side of the legs yellowish-pink; the base of the forewing and the proximal margin of the hindwing red. Expanse of the wings: 21 mm. Costa Rica.
- fininigra*. **L. fininigra** *Kaye* (12 f). Head black with fine white dots above and below the base of the antennae; antennae black, before the tips white; palpi black, at the ends of the joints whitish-curved. Thorax and abdomen above orange; the 3 last segments black with a posteriorly, metallic-green reflection; underside quite black, the large ventral valve silvery white. The base of the hyaline wings is extensively orange, the veins and margins narrow black, of the same colour is the extensive apical spot and a spot below the lower median vein. Described from South Brazil (Santos). — Before me there is from the Coll. SEITZ a whole series of specimens taken by him in Santos in November. In some specimens there is a black dorsal line to be seen, reaching differently far anteriorly from the hindmost black segments, though always leaving the first ring orange; it may be denominated **dorsilineata form. nov.** (12 f).
- metamela*. **L. metamela** *Dogn.* Whether and to what extent this species having remained unknown to me is to be united with the preceding, I cannot tell. The short description coincides, except the palpi which are stated here to be „black, while the two first joints are yellow“. South America (where?).
- pyrgion*. **L. pyrgion** *Druce* (12 f). Head black; forehead, tips of antennae and 2 dots on the vertex white; thorax orange; abdomen black with broad orange lateral stripes, the 3 last rings quite blue-black; venter whitish. Wings hyaline with black veins and margins; the base of the forewings, as well as a part of the subcosta and of the inner margin orange. Panama; French Guiana.
- assecla*. **L. assecla** *spec. nov.* (12 f) greatly approximates the preceding species; it differs by the broader shape of the wings; the stouter structure and more extensive black colour. Head and antennae are quite black; collar and shoulder-covers orange, the latter at the apex black; thorax anteriorly black, only the metathorax orange. Abdomen black-brown, orange-yellow lateral stripes reach from the base only as far as the 3rd segment. The wings are hyaline with narrow black margins; on the base of the inner-margin lies an elliptic, orange-yellow spot. Apical spot very broad black. Santos (South Brazil). Type in Coll. SEITZ.
- imitata*. **L. imitata** *Druce* (12 f) is smaller than the preceding and differs by its quite orange-red abdomen exhibiting only on the dorsum a black median stripe which seems more or less broken up into spots; abdominal apex black. Base of the wings without any orange colouring. Expanse of wings: 24 mm. Guatemala; Honduras.
- diaphana*. **L. diaphana** *Sepp* (= *discifera* *Wkr.*, *bura* *Btlr.*, *albifrons* *Möschl.*) (12 g). Body black-brown; collar orange, shoulder-covers inside bordered by orange; forehead and hips white. The abdomen exhibits broad orange-yellow lateral stripes; the ventral valve is yellow. The wings are hyaline, strongly iridescent with black veins, margins, median and apical spots. Guiana to the Amazon. — The larva is yellowish with a brown head and brown subdorsal stripes, thinly haired with hair-tufts on the 1st, 4th and 10th segments, between the two latter with thick and short hair-brushes; it lives on *Serjania* or *Paullinia*.
- inconspicuata*. **L. inconspicuata** *Kaye* (12 g) has a brick-red thorax and shoulder-covers, the rest of the body is black-brown, at the abdomen white sublateral lines. From British Guiana to Matto-Grosso.

L. crocata H.-Schäff. (12 g). Body black, forehead white, collar, shoulder-covers and thorax red-spotted. Forehips white. The 1st abdominal ring exhibits subdorsal grey-white stripes, the 3rd and 4th orange-red spots. In the ♂ the spots of the collar are whitish, the spots of the thorax are absent; ventral valve white. Wings hyaline, veins and margins black, at the base there are subcostally and above the inner-margin small red stripes; the former are absent in the ♂. Cayenne, Rio de Janeiro. *crocata*.

L. flavinigra Jones. Body yellow; terminal joint of the palpus and distal side, vertex, posterior half of the collar, a stripe on the shoulder-covers and a median stripe above the thorax and abdomen black. Anal tuft black, subdorsally yellow; the last 3 rings beneath black, which colour extends sublaterally in front as far as the 4th segment. The base of the hyaline, black-bordered wings is yellow, outside black. Expanse of wings: ♂ 22, ♀ 21 mm. Castro (Paraná). *flavinigra*.

L. chrysobasis Dogn. (12 g). Head black, upper half of the forehead white, palpi black, at the base and below yellow, antennae black. Collar and shoulder-covers orange, the latter outside bordered by black; thorax black, at the sides yellow. Abdomen orange-yellow with a black median line, the four last rings unicolorously black with a blue lustre. Legs orange, middle and hind-hips blackish. Wings hyaline, base of both pair of wings and a subcostal stripe orange-yellow; proximal and distal margins black; broad apical spots. From Colombia and French Guiana. *chrysobasis*.

L. masa Druce (12 g). Body black; anterior side of the palpi, forehead and neck white; shoulders and metathorax with orange-red spots. Tarsi white; base of the abdomen with white lateral spots. Expanse of wings: 20 mm. Mexico (Tabasco); Honduras. *masa*.

L. austera spec. nov. (12 g) is completely sooty blackish-brown on the whole body and thereby very easily recognizable. Only on the head behind the base of the antennae a small whitish dot. The wings are hyaline with narrow, blackish-brown margins, a black apical spot and a slight expansion below the lower median vein. Described according to a female taken by Dr. SEITZ in Santos. Type in the Coll. SEITZ. *austera*.

L. geminata Schaus. Body black; forehips white; ventral valve ochreous-yellow; in the neck two dark red spots. The wings hyaline with black veins, margins, apical spots and a transverse-vein spot. Expanse of wings: 18 mm. French Guiana. *geminata*.

L. peralta Schaus. Thorax and abdomen are more blue-black than in the preceding, head and base of abdomen more brown. Forehead with white scales; on the shoulder-covers a large carmine spot, the 2 spots of the neck being absent. All the rest as in *geminata*. Expanse of wings: 26 mm. Costa Rica (Tuis). *peralta*.

L. klagesi Rothsch. (12 g) is a very variable species. The body is black; the forehead white as well as the base of the collar, the shoulder-covers at the base carmine; the first abdominal ring is white, the second exhibits subdorsal isabel-coloured longitudinal streaks; the whitish ventral valve is uncommonly large and extends as far as the penultimate segment. Forehips and tarsi white, middle and hind legs on the inside white. Wings without any peculiarities. — In a ♂ before me from Guiana the white basal spot is reduced to two subdorsal longitudinal spots; the white spots may also be altogether absent, and on the other hand, there may occur yet red subdorsal spots on the 3rd and 4th segments. Widely distributed in Venezuela and Guiana, found also in Trinidad. It is possible that the *Pheia bisigna* having been described 2 months before by Kaye, which I only know from the description, is identical with it; then the name would have to be altered into: *Loxophlebia bisigna*. *klagesi*.

L. crusmatica Dogn. has a black body posteriorly with a green reflection; forehead and tips of antennae white; shoulder red-spotted. On the first abdominal rings there are 3 subdorsal white spots. Hips and the ventral valve covering two thirds of the venter white. Wings hyaline, somewhat iridescent, bordered by black with a large apical spot and a 4-cornered spot at the inner angle. French Guiana in August. The species may also belong to the preceding. *crusmatica*.

L. rufescens Rothsch. (12 g) has a white forehead and black vertex; the antennae are black, at the tips white; thorax and abdomen are bright orange-red; the first segment black with subdorsal, isabel-coloured longitudinal spots; underside of the venter black, ventral valve white, uncommonly large. Forehips white, legs for the rest black. The wings are hyaline with an orange-coloured base of the forewings; margins, apex and median spot black. Only 1 ♂ from Venezuela known. *rufescens*.

L. semiflava Rothsch. (12 h). Head and thorax are black; the forehead white; antennae black, at the tips white; base of the shoulder-covers orange-spotted; the abdomen is unicolorously orange-yellow. The large ventral valve is brown. The legs are black-brown, forehips and inside of the hind tarsi white. The wings hyaline with narrow black margins and a somewhat broader apical spot. Described according to 2 ♂♂ from Venezuela. *semiflava*.

L. cosmosomoides Rothsch. (12 h) looks like a *Cosmosoma* from the *stibostictum*-group. Head and antennae black, palpi yellow; thorax black, a spot on the shoulders and metathorax orange-yellow; abdomen orange-yellow, 6th and 7th segments black. Forehips reddish-yellow, legs yellow, on the outside of the *cosmosomoides*.

tibiae black. The wings are hyaline with extensive apical and inner-angular spots; costal margin of the forewing at the base hyaline, then black. The radial veins and the first median vein of the forewing, those of the hindwing all orange-yellow. Surinam.

postflavia. **L. postflavia** Druce (12 h) is one of the largest species, easily recognizable by the black abdomen being orange-yellow at the 4 last segments. The other part of the body is one-coloured black, only the forehead, anterior and posterior hips are white. The wings are hyaline with a black base and black margins being somewhat expanded at the apex of the forewing. Cayenne.

vesparis. **L. vesparis** Btlr. (12 h). The head is orange, on the forehead and vertex black and with metallic-blue spots; thorax black and orange. The abdomen is orange, with black and metallic-blue bands, the last segments quite black and blue. The wings are hyaline, very finely bordered by black, slightly broader at the apex. The base is slightly tinged orange; the inner-margin of the hindwing likewise orange, towards the anal angle with black hair. The ♀ has a black central spot and a greater expansion of the black colour at the apex and below the lower median vein. Known from Peru, Bolivia and Colombia.

albicincta. **L. albicincta** Dogn. Body black, anterior body intermixed with single whitish hairs; the 2nd abdominal ring exhibits dorsally a tuft of long white hair, the other rings are yellowish-white, beneath purely white-curved. The hyaline wings exhibit a fine black border being somewhat thickened on the two upper radial veins and in the apex; also the lower half of the transverse vein is black and thickened; proximal margin of the hindwing covered with long black and white hair. Expanse of wings: 26 mm. Peru (Cuzco).

socorrensis. **L. socorrensis** Dogn. The abdomen, being above quite unicolorously blue-black and exhibiting only on the second ring 2 subdorsal white spots, distinguishes the species from the preceding; the underside is blue-black; finely white-curved. Anal hairing ochreous yellow; legs black, at the joints white. Colombia (Monte Socorro).

asmodeus. **L. asmodeus** Druce (12 h) looks exteriorly like a small *Gymnelia*. The body is black-brown; hips, stripes on the legs and the ventral side of the abdomen are orange. The hyaline wings exhibit very fine black margins; the basal half of the proximal margin of the hindwing is orange; the upper radial veins of the forewing approximate each other very much towards the margin, between them the black distal margin projects somewhat inside. Described from Ecuador, a ♂ before me originates from the Colombian West Cordilleras (Monte Socorro, 3500 m) and was taken in July.

parca. **L. parca** spec. nov. (12 h) approximates the preceding species and differs by only half the size and a much greater prominence of the black colour. The head is black, except a crescentiform, yellowish-white spot below the base of the antennae. The basal half of the very short palpi is orange, the terminal joint black. Thorax predominantly black. Abdomen above and laterally black with orange-yellow segmental indentations which, however, are interrupted on the dorsum by black with the exception of the first (being besides more whitish) and third segments. The first ring exhibits a yellow lateral spot; the ventral side is in front quite yellowish-white, posteriorly blackish-curved. Legs black; tibiae and tarsi beneath yellowish. The wings are hyaline, narrowly margined by black, the forewings with a yellowish-brown subcostal stripe. Described according to a ♂ from Colombia (Quindiu Pass, 2300 m). Type in the Coll. SEITZ.

senta. **L. senta** spec. nov. (12 h) greatly approximates the preceding species; it is somewhat larger, has longer and narrower wings; the discocellular is placed more obliquely and the middle radial vein rises nearer to the lower one than in the preceding. Very characteristic is the peculiarly bristly scaling of the large, brown median spots. The black-brown body is more intensely spotted orange-yellow, otherwise in the same way as in *parca*. On the under surface the costal margin and median spot of the forewing are bright orange; the legs are quite orange, only the forelegs with a blackish hue at the femora and tibiae. Described according to 3 ♂♂ from Colombia; type in the Coll. SEITZ.

multicincta. **L. multicincta** Dogn., based upon a ♀ and a damaged ♂, is likewise nearly allied to the preceding species, particularly *parca*. From the latter it deviates by its quite white ventral side, yellowish white hips and the yellow abdominal rings being, however, dorsally not interrupted by black, also the abdominal apex is yellow; the thorax exhibits 3 pair of yellow spots. Expanse of wings: 22 mm. Quindiu Pass (2400 m) in September.

eumonides. **L. eumonides** Druce (12 h) approximates the preceding species and differs above all by its white forehips and ventral side. The abdomen is more blue-black with 2 white dots on the 2nd segment. Base and margins of the wings are much broader black. The forewing shows a large black central spot and a black transverse spot between the middle of the inner-marginal vein and the base of the lower median vein. The inner-marginal part of the hindwing is black. Ecuador.

triangulifera. **L. triangulifera** Fldr. (12 i) is quite differently coloured and resembles in some way *Leucotmemis nexa* by the black wings being provided with single, small hyaline spots. Black, forehead and shoulders with metallic-blue scales. shoulder-covers white-spotted; hips red; metathorax blue and white spotted; the abdomen exhibits dorsal and lateral rows of metallic-green spots. The forewings exhibit triangular hyaline spots below the base of the cell and in the cell, as well as in the ♀ above the upper radial, the latter being absent in the ♂; hindwings with a small hyaline spot below the base of the cell. Expanse of wings: 38 mm. Venezuela; Amazon.

24. Genus: **Mesothen** *Hmps.*

Differs from the preceding genera particularly by the angular discocellulars of the hindwings. On the forewing the upper median vein rises from the cell-angle, or near it; the middle radial above it, as in *Loxophlebia*.

M. bisexualis *Dogn.* Head black with a white forehead; thorax and abdomen are yellow, the 3 last rings and the prothorax black. The hyaline wings in the ♂ exhibit black veins and margins, apical spot and inner-angular spot; only the extremest base of the proximal margin is yellow. In the ♀ the whole inner-margin, two thirds of the costa, the subcostal and median, as well as the greatest part of the submedian and of the lower median vein are yellow. Expanse of wings: 21 to 22 mm. East Colombia. *bisexualis.*

M. temperata *Schaus.* Head and palpi black, forehead white. Thorax black with dark yellow shoulder-covers. Abdomen deep yellow, on the 1st ring a black dorsal spot; on the next 3 rings a large spot suffused by steel-blue, extending as far as the sides; the 2 last segments are black, too, with a steel-blue reflection. Thorax yellow, ventral valve at the end black. Femora yellow, anterior and middle tibiae and tarsi black, posterior tibiae and tarsi yellow, at the joints black. Wings hyaline with black veins, margins, apical and inner-marginal spots; subcostal centre yellow. Expanse of wings: 29 mm. Costa Rica. *temperata.*

M. albifrons *Schaus.* Head and thorax black, forehead white; shoulder-covers yellow-striped; underside and legs yellow, only the joints and tarsi black. Abdomen yellow, the 3 last rings black. Wings hyaline with black veins and margins; apex of the forewing broadly black; the base of both wings is somewhat yellow-haired. Expanse of wings: 25 mm. Colombia. *albifrons.*

M. albilimbata *Dogn.* Palpi black, forehead laterally white, in the middle black; vertex and antennae black; collar and shoulder-covers yellow, in front black-margined; the thorax is otherwise black with a yellow longitudinal and white transverse band; the 4 first abdominal rings are yellow with a black margin, the others above black, white-banded, beneath all yellow, only the 3 last ones black-curved. Wings hyaline with black nervures, a fine black margin and a somewhat broader black apex and yellow subcostal band; the median is partly yellow; at the base and inner-margin some yellow hairs. Expanse of wings: 31 mm. From Colombia at an altitude of 3200 m. *albilimbata.*

M. doris *Druce* is a species of an expanse of about 40 mm, with a quite pale yellow body; antennae, terminal joint of the palpus and a dorsal macular series on the abdomen black. Wings hyaline with black nervures and margins, the costal margin and veins at the base yellow. Colombia. *doris.*

M. flavicostata *Druce.* Body yellow; palpi and antennae black, the shaft on the latter half-way white. Collar, thorax, and the abdomen dorsally on all the segments, with black spots, the last segment quite black. Legs yellow. Base and costal margin of the forewing is yellow, veins, margins and apical spot black. South East Peru. *flavicostata.*

M. nomia *Druce* has a chrome-yellow body; antennae black, collar bordered with black. The abdomen is banded with metallic-blue, the 2 last segments are quite blue. Wings yellowish hyaline with black veins, borders and apical spot; base of the forewing and costal margin as far as the cell-end yellow. Expanse of wings: 35 mm. Colombia. *nomia.*

M. mysia *Druce.* Head, antennae, palpi and legs are black, the rest of the body yellow, the abdomen with black bands. Wings hyaline with black veins, margins and apical spot. Expanse of wings: 32 mm. South East Peru. *mysia.*

M. rogenhoferi *Schaus.* Head black with a white forehead and yellow hind head, thorax and abdomen yellow. The thorax exhibits above a black middle stripe; the abdomen is dorsally and laterally black-striped, the stripes vanishing posteriorly. Joints and tarsi black. Wings hyaline with black veins, margins and apical spot, base of the inner margin yellow. Expanse of wings: 30 mm. Brazil (Rio de Janeiro). — **perflava** *Kaye,* which may belong hereto, differs by its black-striped shoulder-covers, absent black lateral stripes and black last abdominal ring. Described from Santos. *rogenhoferi.* *perflava.*

M. ockendeni *Druce.* The head with antennae and palpi is black, the forehead white, thorax and abdomen orange-yellow. The abdominal rings are black-spotted, the last ring quite black, so are the thorax and legs. Wings hyaline with black veins, margins and apical spot. Expanse of wings: 45 mm. South East Peru. *ockendeni.*

M. dorsimacula *Rothsch.* Head black with fine white dots; antennae black, white before the tips. Thorax and abdomen golden orange; the abdomen exhibits on the first 2 rings a black middle spot; the 2 penultimate segments are black, the last being metallic-blue. Legs brown, forehips white. Wings hyaline with black veins, margins, inner-marginal and apical spots, the base being orange, distally black. Length of forewings: 17 mm. Costa Rica. *dorsimacula.*

M. aurantiaca *Dogn.* Head black, forehead white, thorax and abdomen orange; the tips of the shoulder-covers, 2 dots on the thorax blue-black, as well as 5 dorsal spots from the 2nd to 6th abdominal rings; on the 3rd to 6th ring there are besides somewhat smaller lateral spots; the 3 last rings are black with a green reflection. *aurantiaca.*

The hyaline wings with black veins, margins and apical spot are at the base and in the subcostal space orange. Expanse of wings: 32 mm. South East Peru.

- petosiris.* **M. petosiris** Druce (12 i) from Colombia, Ecuador and Bolivia has an orange-yellow body; collar and shoulder-covers are margined with black; the abdomen shows black and blue spots being united to transverse bands from the 3rd ring, the last segments are quite black and metallic blue. The hyaline wings exhibit orange-yellow stripes at the costal and inner margins which are black like the distal margins and the apical spot. —
- erubescens.* In **erubescens** form. nov. (= ab. 1 *Hmps.*) the colour of the body is orange-red.
- ignea.* **M. ignea** Druce (12 i) has a black head, otherwise the body is orange-red; on the mesothorax two, on the metathorax one black spot. The dorsum shows a series of black spots growing smaller posteriorly; the last segment is black; laterally and underneath on the last segments black spots; legs black-brown. The hyaline wings have an orange-red base, black margins and apical spots. Mexico.
- samina.* **M. samina** Druce (12 i). Head and thorax black; the 2 first palpal joints are orange, also the forehead, vertex and border of the collar, stripes on the shoulder-covers and legs. Abdomen orange with black transverse bands growing broader on the dorsum until they flow together and exhibiting metallic-blue spots. Wings hyaline with fine black veins, margins and apical spots; at the base of the forewing there stands an orange dot. Expanse of wings: 38 mm. Panama (Chiriqui).
- ethela.* **M. ethela** Schaus (12 i) entirely resembles a small *Cosmosoma stibostictum*: thorax and apex of the orange-yellow abdomen are black; forehead and shoulders white-spotted; dots behind the antennae and forehips white. The hyaline wings show black margins and apical spot. Costa Rica.
- montana.* **M. montana** Schaus. Anterior body dark brown, abdomen yellow; the rings 2 to 6 show 2 rows of black spots on the dorsum. Legs yellow, tarsi and a part of the hind tibiae brown, wings hyaline with fine brown veins, margins and apical spots. Expanse of wings: 39 mm. Costa Rica (Volcano Poas).
- epimetheus.* **M. epimetheus** Schaus. Head and abdomen black, the latter with orange-red subdorsal spots on the 3 first rings; thorax orange-red with a black spot in the middle. Wings hyaline with black veins, margins, inner-marginal spot and apical spot; the base and a short inner-marginal stripe orange. Expanse of wings: 26 mm. Brazil (Novo Friburgo).
- pyrrha.* **M. pyrrha** Schaus (12 i). Head and abdomen are black, the thorax orange; the tips of the antennae, the front of the palpi, two spots on the forehead and the hips are white; the ventral valve and an indistinct longitudinal stripe on the dorsum of the first ring are white; in the ♀ there are besides white lateral stripes on the first segments. The wings are hyaline with black margins. Widely distributed in Mexico, Colombia, Guiana; 1 ♀ before me also from Peru (Cuzco).
- caerulei-*
corpus. **M. caeruleicorpus** Schaus. Body deep blue. Tibiae rosy red, tarsi black. Wings hyaline with black margins, veins and apical spot. Expanse of wings: 30 mm. Bolivia.
- roseifemur.* **M. roseifemur** spec. nov. (12 k) is very nearly allied to the preceding species, differing particularly by the hips and femora being rosy red and not the tibiae, whereas the tibiae and tarsi are black-brown. The whole body is brown-black, above on the abdomen with an indigo-blue gloss. The hyaline wings have narrow black margins and large apical spots. Described according to 1 ♂ from Colombia (Quindiu Pass 2100 m); type in Coll. SEITZ. It may also be a form of the following species with a black collar and black shoulder-covers, the red lateral spots at the 1st abdominal segment being absent, too.
- erythaema.* **M. erythaema** Hmps. (12 k) is a large, beautiful, easily recognizable species; head, thorax and abdomen are black, the latter with a blue gloss. Collar and shoulder-covers, hips and femora, as well as lateral spots at the first abdominal segment are carmine, the shoulder-covers bordered with black. The wings are diaphanous with black margins, veins, apical spots and middle spot of the forewing. Colombia, Bogotá.
- flaviventris.* **M. flaviventris** Druce (12 i). Body black; forehead and tips of antennae white, shoulder-covers orange-spotted, of the same colour are the last rings of the abdomen; the first exhibits lateral white spots. Wings hyaline with an orange dot at the base; veins, margins, discal, apical and inner-marginal spots being black. Expanse of wings: 26 mm. Panama (Chiriqui).
- catherina.* **M. catherina** Schaus. Body black; spots on the shoulder-covers and at the sides of the 4th abdominal segment carmine. Wings hyaline with black veins, margins and apical spot. Expanse of wings: 30 mm. Brazil (Sa. Catharina).
- nana.* **M. nana** Schaus. One of the smallest species with quite black body, only the shoulders exhibit a red spot. Wings hyaline, veins, margins, apical spot black, also a large spot at the cell-end and one at the inner angle, the forewings are black. Expanse of wings: 17 mm. French Guiana.
- endoleuca.* **M. endoleuca** Druce. Body black with blue-grey subdorsal lines on the abdomen. Wings hyaline with black veins, margins and apical spots. Expanse of wings: 25 mm. Venezuela.
- desperata.* **M. desperata** Wkr. (12 k) is a very small, insignificant species; the body is unicolorously greyish black; the abdomen exhibits above indistinct, lighter subdorsal stripes. The hyaline wings have narrow, black distal

margins. Distributed from Panama through Guiana and Brazil as far as Paraguay and Argentina; it flies in day-time on compositae.

25. Genus: **Mimagyrta** *Hmps.*

Is nearly allied to the following, from which it differs by the lower radial nervules rising separately; the upper radial rises somewhat below the upper cell-angle, the most central subcostal vein being absent; the cell of the hindwing is much shorter; the upper median vein rises from the lower one shortly before the margin.

M. pampa *Druce* (12 k) strikingly resembles an *Agyrta*: the abdomen and part of the wings with a blue gloss, the wings exhibit hyaline spots exactly like there. The base of the palpi, sides of the forehead and stripes on the hips, femora and venter are white; Amazon; also from Peru (*Pachitea*).

M. pulchella *Klages* strikingly resembles *Chrostosoma tricolor* *Fldr.* (12 m). The body is above black-brown, beneath white inclusive of the legs; front of the palpi, forehead, shoulders and mesothorax white-spotted; subdorsal stripes and interrupted lateral stripes on the abdomen whitish; on the collar metallic-blue scales. The black-brown forewings exhibit at the costal base a white dot, below the cell-base a broad, yellow stripe, an oblique, yellow spot in and below the cell-end and an oblique, hyaline band beyond it; base of the inner margin metallic blue. The hindwings exhibit a yellow longitudinal band below the cell and a blue inner margin. Venezuela.

26. Genus: **Chrostosoma** *Hmps.*

In many ways allied in its exterior to the genus *Saurita* from which it differs by its shorter palpi which do not reach the vertex, as well as by the lower radial being longer pedicellated with the lower median vein of the hindwing; furthermore, the uppermost subcostal vein of the forewing rises on a common pedicle with the other subcostal veins and not freely from the cell.

Ch. decisa *Wkr.* (12 k) has like the following a black-brown body, carmine-red spots on the shoulder-covers and on the middle of the first abdominal ring; metallic blue lateral spots; the underside is white; in contrast with the following species, the vertex and metathorax are spotted with metallic-blue, and the brown marginal band of the whitish hindwings sends forth a long continuation towards the base below the cell. Amazon, Bolivia.

Ch. haematica *Perty* (= *zantes* *H.-Schäff.*, *fenestrina* *Bthr.*, *chalconitis* *Druce*) greatly resembles the preceding, but on the vertex the blue colour is absent, the wings are in the basal part more smoky hyaline and on the hindwings the continuation of the marginal band towards the base is shorter. From Ecuador and Brazil.

Ch. viridipunctatum *Rothsch.* (12 k) is allied to the preceding species and is easily discernible by entirely hyaline forewings with a broad, black-brown middle band and apical spot. Head, metathorax and abdominal sides are spotted in a bright metallic green. Described from Brazil.

Ch. schausi *Rothsch.* (12 l). Head and thorax metallic green, shoulders carmine; first abdominal segment carmine; the rest of the abdomen metallic green, black-curved and with a black middle line. The antennae are black; legs black-brown, at the tibiae with metallic-green spots; hind tarsi white. The hyaline forewing exhibits a broad, black middle band and black apical spots. This magnificent, small species has become known from Panama (Chiriqui) and Ecuador (Paramba).

Ch. chrysidia *spec. nov.* (12 l) has a body similar to that of *viridipunctata*; body black. Forehead, vertex, meso- and meta-thorax with large, green metallic spots; first abdominal ring above carmine, the other segments exhibit uncommonly large, metallic-green, brass-lustrous subdorsal spots. Forehips white; palpi, legs and antennae quite black. The wings are brownish hyaline with narrow, black-brown margins and veins. This magnificent species originates from Colombia (Rio Aguaca Valley, 2000 m), type in Coll. FASSL.

Ch. fumosum *Schaus.* Body black, on the shoulders, shoulder-covers and first abdominal ring above spotted in carmine. Forewings smoky-brown diaphanous, at the distal margin blackened, veins and fringes fine black. Hindwings semi-diaphanous black. Expanse of wings: 25 mm. Costa Rica.

Ch. dstricta *spec. nov.* (12 l). Sooty black; vertex and shoulders red-spotted. The metathorax exhibits a square, scarlet spot, followed by a whitish spot on the first abdominal segment. The wings are sooty hyaline, iridescent with very broad, black veins; margins, apical spots of both pair of wings and the inner-marginal half of the hindwing are black. Described according to a male example from Panama (Lino, 800 m) (FASSL).

Ch. fassli *spec. nov.* (12 l) resembles the preceding, though it is larger, with broader wings. Head and 1st abdominal ring quite brownish-black, shoulder-covers red-spotted. Apex of the forewing broader brownish-black. Collar and Abdominal sides with a blue gloss. East Colombia (2200 m). (FASSL.)

- anthracina*. **Ch. anthracina** *spec. nov.* (12 l) resembles *Amyces anthracina* (20 i), particularly in the female: the body is sooty black. Collar, shoulders and first abdominal ring subdorsally with minute scarlet spots; below them lateral whitish spots on the first segment. Forewing in the first two thirds sooty black, warming into red-brown towards the following whitish marginal third; at the apex a narrow, grey marginal spot; at the base, below the median, a red streak-like spot. Hindwings hyaline, on the veins, at the apex and inner angle broadly blackened. The ♂ is in the basal part, in and below the cell, very thinly sealed, so that oblong hyaline spots are produced here. This very interesting species is before me in both sexes from East Colombia (Paeho, 2200 m). (FASSEL.)
- mosca*. **Ch. mosca** *Dogn.* Body unicolorously black, above with a slight blue-green reflection; the first abdominal ring is red. Wings hyaline with black veins and margins. Expanse of wings: 22 mm. Ecuador (Loja).
- echemus*. **Ch. echemus** *Cr.* (= *dolens* *Wkr.*, *stulta* *H.-Schäff.*) (12 k) differs from *decisa* and *haematica* which are somewhat larger by the hyaline, not white basal half of the hindwing. The body is brown-black; on the shoulders and on the middle of the first abdominal segment red-spotted; on the sides of the abdomen indistinct, metallic-blue, small spots. The ventral side and the femora are whitish. The dull-hyaline wings are blackish brown at the margins and on the veins, the disc is clouded in brownish round the middle spot. The hyaline hindwings are blackish-grey in the marginal half and on the broad inner-marginal part. Guiana; Amazon.
- unxa*. **Ch. unxa** *Druce* (12 l). Two subdorsal, red spots on the first abdominal segment, instead of one dorsal spot, separate the species from the preceding; vertex and collar with metallic-blue scales, on the ventral side only the first 4 rings are white. The hyaline wings have a yellow tinge. Expanse of wings: 32 mm. Panama (Chiriqui).
- trimaculatum*. **Ch. trimaculatum** *Strand* in the marking greatly resembles *decisa* *Wkr.* from which it differs above all by the presence of the upper median vein of the forewing, being absent in *decisa*; furthermore, the black apical spot of the forewing is cut off straight, inside not concave; also the discal band is sharply defined; the red spot on the 1st abdominal ring is sharply marked, triangular, showing with its apex in front. Expanse of wings: 27 mm. Peru (Urubamba).
- cardinalis*. **Ch. cardinalis** *Schaus* (12 m) has an entirely scarlet body; only the head is black with a white forehead; on the red legs the tibiae and tarsi are blackish-brown; the hyaline wings with black margins and apical spots are at the base of the forewings scarlet; the inner-marginal part of the hindwing is black, at the border red-haired. At once distinguishable from the exteriorly most similar *Cosmosoma melanopera* (13 k) by the quite red abdomen without the black anal apex. Colombia: 1 ♂ before me from the Rio Aguaca Valley, West Cordilleras, 2000 m. (FASSEL.)
- semi-rubrum*. **Ch. semirubrum** *Hmps.* (12 m). Head, thorax and the 3 last abdominal rings are black; forehead white-spotted; on the shoulders scarlet spots; the first abdominal segments scarlet. The hips and posterior tarsi are white. The hyaline forewings exhibit a black median band and very extensive, black apical spots. From Brazil (São Paulo).
- pellucidum*. **Ch. pellucidum** *Schaus* is easily recognizable by the ochreous yellow body, only the 2 last abdominal rings, antennae and legs are black, the latter somewhat yellow striped. Wings hyaline with black veins, margins and apical spots, the forewings at the base orange. Expanse of wings: 25 mm. Peru (Carabaya).
- sitiona*. **Ch. sitiona** *Schaus* differs from the preceding by its larger size, black head, antennae and palpi, and quite black legs with yellow hips. Expanse of wings: 29 mm. Costa Rica.
- patricium*. **Ch. patricium** *Schaus*. Body brown-black, forehead metallic-blue, similar spots are on the collar and thorax, the shoulders being red-spotted. First abdominal ring with subdorsal, earmine spots and laterally blue-spotted, venter white. Forehips opalescent white. The hyaline forewings exhibit a broad, black middle band terminating into the inner angle, and a large apical spot; hindwings with a broad, black border. Expanse of wings: 29 mm. Costa Rica.
- tricolor*. **Ch. tricolor** *Fldr.* (12 m) greatly resembles *Mimagyrta pulchella*. Body black, anterior body marked with white, abdomen subdorsally striped in a bluish white, venter white. The black forewings are at the inner-marginal base metallic blue; in and below the cell-end there is a large, orange oblique spot, behind it a hyaline oblique band. Hindwing in the inner-marginal part metallic-blue; in below and behind the cell a long, narrow hyaline spot. Expanse of wings: 30 mm. Amazon.
- marathum*. **Ch. marathum** *Druce*. Body quite black. Collar bordered with red. Forewings smoky-brownish hyaline; behind the middle a broad oblique band of a semi-diaphanous, white colour, extending from the costal margin to the inner angle. Hindwings hyaline, at the apex and inner margin dusted with black. Expanse of wings: 26 mm. Ecuador.

27. Genus: **Nyridela** Lucas.

This genus contains only 2 very similar, large, robust species with hyaline, broadly black-margined wings with a black median band. The erect palpi project but little beyond the vertex; in the ♂ a large valve covers the ventral side of the basal abdominal rings. On the forewing the lower median vein rises near the lower cell-angle and is strongly curved downwards, the upper median vein and the 2 lower radial veins all rise separately from the lower cell-end. On the hindwing the discocellular runs so very obliquely that the cell does not become visible.

N. xanthocera Wkr. (9 k). From the similar *chalciope* Hbn. this species differs by the quite yellow antennae, the blackish-blue forehips, and the metallic-blue colour being less prominent on the abdomen. Widely distributed in Central America, so in Mexico, Guatemala, Costa Rica, and Panama. *xanthocera*.

N. chalciope Hbn. (= *acroxantha* Perty) (9 k). Very similar to the preceding species from which it differs by the black antennae being yellow only at the tips, the white forehips and the metallic bluish green spots being more prominent on the abdomen. It flies not only in Colombia (Bogotá) and Brazil, but also in Cuba. *chalciope*.

28. Genus: **Leucotmemis** Btlr.

Exactly like *Cosmosoma*, but the upper median vein rises in common with both the lower radial veins from the lower cell-end, or at least shortly before it, but never separated so far as in the following genus. The species are mostly distinguished by a broad, black middle band of the forewings.

L. dorsalis Wkr. (15 a). Black-brown; palpi and stripes on the shoulder-covers orange; the abdomen exhibits broad orange lateral stripes; of the same colouring is the underside. The black-brown forewings exhibit hyaline stripes in and below the cell and a yellowish hyaline spot behind the cell between the upper median vein and the lowest subcostal; the veins crossing it are yellow. Hindwings black-brown, at the base orange, behind the cell with a yellow hyaline, orange-veined spot. Expanse of wings: 20 mm. Amazon. *dorsalis*.

L. varipes Wkr. (= *albiventris* Wkr., *syrphiformis* H.-Schöff.) (15 a). Head and thorax black, forehead and collar bordered with white. Legs white and brown with yellow tarsi. Abdomen carmine with a black apex, and white and brown subdorsal spots on the first segment; venter white. Wings hyaline, towards the margins dusted with brown, the veins, costal and inner margin being brown in the ♂, yellow in the ♀, with a very large, brown discal spot being confluent with the inner-angular spot. Expanse of wings: 24 mm. Amazon. *varipes*.

L. margariphera Btlr. (12 m) is a large, beautiful species with a black head and thorax; on the vertex and collar blue spots; on the shoulder-covers a small, orange-yellow spot; the abdomen is carmine; the first segment black with subdorsal blue dots and orange-yellow lateral spots; on the other segments subdorsal, opalescent, whitish spots; the 3 last rings are black, with metallic-blue spots; the underside is yellowish-white. The wings are faintly yellowish hyaline; veins, costal and inner margins yellow; a metallic-blue spotted discoidal spot, apical and inner-angular spots are black. Amazon (Pará). *margariphera*.

L. pleuraemata Hmps. (12 m). Black-brown, base of the palpi white; spots on the collar and broad lateral stripes on the abdomen are carmine; on the first abdominal ring the latter are yellowish; hips and ventral side yellowish-white. The wings are hyaline with black-brown margins, median band and apical spots. Brazil (Sa. Catharina). — **v. paranensis** Schrottky (26 k), from Paraguay and Argentina which may be a species of its own, is considerably smaller, the palpal base being red instead of white, the hips and venter of a pure white, not yellowish. Flying on compositae. *pleuraemata*.

L. tenthredoides Wlkr. (12 m). Head black, on the vertex with metallic-blue spots, forehead downward white; collar black and blue; thorax orange, shoulder-covers bordered with black; abdomen orange, the last 3 segments black and blue spotted, in the ♂ with a black spot on the preceding ring. The wings are hyaline, the margins, median band and apical spot black; at the base of the costal margin a blue spot; subcosta, inner margin and the veins behind the median band orange; base of the hindwing orange. Distributed from Guiana to the Amazon. *tenthredoides*.

L. hemileuca Btlr. (12 m) is allied to the preceding species from which it differs by the absence of the metallic-blue spots on the base of the forewing and at the end of the abdomen; it is also considerably smaller. The thorax is black, only the basal half of the shoulder-covers is orange; abdomen orange, the two last segments black, on the preceding segment a black spot; underneath whitish. In the ♀ the black median spot of the forewing remains separated and hardly touches also the inner margin, whereas the ♂ has a developed median band. Amazon. *hemileuca*.

- intersecta*. **L. intersecta** Wkr. (12 m) is smaller than the preceding species from which it differs by quite black shoulder-covers; the otherwise unicolorously orange-yellow abdomen being beneath white exhibits the 3 last segments coloured black. Brazil (Ega).
- latilinea*. **L. latilinea** Wkr. (14 m). Head and thorax black, shoulders orange spotted; forehips white; abdomen yellow, the 3 last segments and part of the fourth black, subdorsally blue-spotted. Wings hyaline, veins and margins broad black, at the costal base of the forewing a blue spot; a broad, black postmedian band. Expanse of wings: 36 mm. Brazil.
- omole*. **L. omole** Druce (12 m). Likewise allied to the preceding species, smaller than *latilinea* from which it differs by the orange-yellow colouring of the metathorax and the base of the hindwing. Ecuador.
- bella*. **L. bella** Kaye. Body orange; forehead white, on the vertex 2 metallic-blue, small spots. The abdomen exhibits above a metallic-blue macular stripe, the last 4 rings are black with blue scales. Wings yellowish hyaline, two thirds of the costal margin and the basal half of the inner margin orange; apex and distal margin black. Hips and femora orange, tibiae black, tarsi white. Expanse of wings: 27 mm. Brazil (Santos).
- endochrysa*. **L. endochrysa** Dogn. Head and thorax black-brown, palpi and legs yellow, as well as the base of the shoulder-covers and the abdomen, the 2 last rings of which are black above. Wings hyaline with a broad black apical spot, base black, intermixed with yellow scales. The veins partly yellow. Expanse of wings: 27 mm. French Guiana.
- torrida*. **L. torrida** Wkr. (13 a) has an orange-yellow body; vertex, collar, shoulder-covers and mesothorax black-spotted. The abdomen exhibits black-blue segmental indentations and dorsal spots, the two last segments are black and blue spotted. The wings are yellowish hyaline with a narrow middle band and a black apical spot. Inner margin of both pair of wings orange. Amazon.
- climacina*. **L. climacina** Btlr. (13 a) is very closely allied to the preceding species from which it is discernible by the considerably smaller extent of the hyaline spot behind the middle band. Head and thorax are orange, the palpi laterally black; the shoulder-covers bordered with black; the abdomen is black with large, orange-yellow, subdorsal and lateral spots, the last segments are metallic-blue. Femora black-banded, tarsi black. Middle band and apical spot of the forewing very broad; subcostal and inner-marginal stripes orange; the hyaline spot behind the middle band is hued with orange, the veins crossing it are orange. Brazil (Espírito Santo).
- emergens*. **L. emergens** Wkr. (13 a). Head and thorax are black, the shoulder-covers orange; the abdomen is black with very broad, subdorsal, orange-yellow longitudinal stripes, beneath whitish except the two last segments. Antennae black with white tips. The wings are hyaline, at the base orange; veins black, behind the cell orange-yellow. Margins, a broad apical spot and small cellular spot black. Amazon.
- felderi*. **L. felderi** Roths. (13 a) strikingly resembles the preceding species from which it is distinguished by an orange-yellow collar and much smaller size; the abdomen is underneath orange. The base of the hindwing is more extensively orange. Amazon.
- albigutta*. **L. albigutta** Schaus has a black body; vertex blue, collar and shoulders white and blue spotted; the thorax exhibits 2 large, opalescent white spots; at the abdomen subdorsal and lateral green stripes, underneath violet. Wings hyaline with black veins, margins and middle spot. Expanse of wings: 23 mm. Surinam.
- thoracica*. **L. thoracica** Schaus. Head and abdomen black, vertex blue, antennae black with white tips; the abdomen exhibits subdorsal green spots and broad green lateral stripes. Neck and thorax ochreous yellow. Wings hyaline with black veins and broad margins; the cell of the forewing is dusted with black and exhibits at the end a large, black middle spot. Expanse of wings: 30 mm. French Guiana.
- ornatula*. **L. ornatula** Wkr. (13 a) shows the way on which the following species *nexa* may have deviated from the generic type. Black; collar blue-spotted; on the shoulders small orange-yellow spots. The second abdominal ring exhibits orange-yellow lateral streaks; the last segments show metallic-blue spots. The wings are hyaline, with black margins, middle-band and apical spots; the forewing at the base with an orange-yellow and a blue, small spot. On the under surface the bases of the wings are orange. Amazon.
- nexa*. **L. nexa** Herr.-Schäff. (13 a) does not show any alliances and nearly resembles a *Calonotus*. Black; forehead and neck white; vertex, collar, thorax and legs with silvery blue spots; shoulder-covers, sides of the thorax and hips with white spots; the first abdominal ring exhibits blue dorsal and white lateral spots, the other segments exhibit broad dorsal, subdorsal and sublateral, golden-green longitudinal stripes. The black forewing exhibits at the base of the costal margin a white and blue dot, then a narrow, small hyaline stripe; below the median a blue spot. Below the discocellular there is a white hyaline spot, between the veins 3 and 7 another one. Hindwings with small hyaline spots behind and mostly also below the cell. Widely distributed and common from Mexico to Brazil.

L. insperata Wkr. (13 a) has a black body; on the forehead, vertex, collar, shoulders, metathorax and *insperata*. thorax there are metallic-blue spots; the first abdominal ring exhibits lateral, metallic-blue spots; the other segments with dorsal and lateral series of green-silvery spots. Forehips posteriorly carmine. Forewings black with brown-smoky hyaline spots in and below the cell, as well as behind the large, black middle spot. Hindwings hyaline with black margins. Amazon (Pará).

29. Genus: **Cosmosoma** Hbn.

This Syntomid genus contains most of the species; they are rather homogeneously looking insects, some small, others more than medium-sized. The wings are hyaline with black margins; the latter growing broader, mostly also the black apical spot increases in size and the black colour on the lower median vein dentately turns inwards. The discocellular is black in a variable extent, it may also be prolonged in the shape of a band as far as the inner angle. The abdomen is mostly yellow, red or black, frequently ornamented with magnificent blue or green metallic spots. On the forewing, being rather broad, the upper median vein rises before the lower cell-angle, while the two lower median veins rise directly from it, the upper one from the upper cell-angle; the uppermost subcostal vein comes separately out of the cell, the others stand on a common footstalk. On the hindwing the lower radial and the lower median vein are petioled, the first median vein is absent or rises close before the margin from the lower one; the subcostal and first radial vein come from the upper cell-angle.

C. demantria Druce (13 a). A large, strong species with a scarlet body; the head is black, on the forehead *demantria*. and vertex with metallic-blue spots; collar and shoulder-covers at their base blue and black spotted; thorax with a black middle stripe and a blue spot on the metathorax; the abdomen, from the second segment, exhibits a series of blue and black dorsal spots; underneath black; the ventral valve at the sides white; antennae at the tips white. Dominica.

C. oroyanum Rothsch. (13 b). Head, collar and outer half of the shoulder-covers black, with metallic- *oroyanum*. blue spots; thorax and inner half of the shoulder-covers brick-red; the abdomen is black with metallic-blue dorsal spots, laterally on the 4 first segments brick-red; behind them with metallic-blue spots. Ventral valve blackish-brown with white lateral spots. The forewing is without the middle spot. Legs blackish-brown, forehips red. Peru.

C. exomelan Zerny (= mathani Rothsch. pr. p.) (13 b). Head black, on the vertex metallic blue, thorax *exomelan*. deep carmine, abdomen black, on the first segment subdorsal, carmine spots; the last segment and subdorsal spots on the preceding ones metallic green. Legs blackish-brown, forehips carmine. Antennae black, before the tips white. Colombia (Cundinamarca).

C. ignidorsium Hmps. (13 b). Head and collar are black with metallic-blue spots. Thorax and first *igni-* abdominal ring scarlet, generally also lateral spots on the second segment; shoulders with black and blue spots. *dorsium*. The abdomen, beginning from the 2. ring, is black with dorsal and lateral series of blue spots; the ventral valve is laterally white-spotted. The hyaline forewings exhibit a short red inner-marginal streak. Brazil; also in Paraguay, taken in April on compositae. The species is the true copy of *Poecilosoma chrysis* (14 i), but always easily recognizable by the first radial of the forewing rising from the upper cell-angle.

C. rubriscapulae Kaye (13 b) is easily discernible from the preceding by the black middle of the thorax, *rubrisca-* besides the dorsal blue spots are absent on the abdomen, the lateral spots being more green; the wings are more *pulae*. pointed and exhibit a large, black middle spot. Flying in day-time in July in Trinidad.

C. rubritarse Schaus. Head and thorax black, spotted somewhat blue; antennae with white tips. *rubritarse*. Abdomen above carmine with a black dorsal line being somewhat broader on the first ring; the last 2 rings black, blue-spotted; laterally there are 3 triangular, black, blue-scaled spots. Legs red, outside black-striped. Wings hyaline, veins, margins, apical spots and discal spot black. Expanse of wings: 38 mm. Costa Rica.

C. subflammum Wkr. (= panopes H.-Schäff.) (13 b) has its body above quite black with metallic- *subflam-* blue spots, whereas the under side of the thorax is vermilion; the legs are likewise red, in some places black- *num*. spotted. The hyaline wings exhibit black veins and broad black margins. — From Surinam, Venezuela and the Amazon. In v. **lucia** Schaus from Santa Lucia the hindlegs are quite black except the red hips. *lucia*.

C. myrodora Dyar (= augc Neum. & Dyar, omphale Harr.) has formerly been confounded with the *myrodora*. following which it also resembles exactly, except the 1st abdominal ring being red also above and the dorsal black beginning only from the 2nd ring. Expanse of wings: 34 mm. Eastern coast of Florida; Indian River: Palm Beach; Miami.

C. auge L. (= omphale Hbn., melitta Möschl.) (13 e). Head black with metallic-blue spots on the *auge*. forehead and vertex. Palpi black, at the base vermilion, antennae black with white tips. Collar black with

blue spots, thorax and the 4 first abdominal rings laterally vermillion. Abdomen otherwise black with metallic-blue dorsal spots, on the 4 last rings also blue lateral spots. Legs red, in some places black. The large ventral valve in the ♂ laterally silvery white. Immediately discernible from the very similar following species by the absence of the triangular blue lateral spots on the first abdominal segments, the discocellular of the forewing being also only quite narrow black. Widely distributed and common from Mexico through the whole of Central America and Brazil as far as Uruguay, also in St. Thomas, Cuba and Jamaica. — The larva, being yellowish on the first and last segments, is covered with black and white hair; on the fifth and eleventh segments there are lateral, dense, black hair-tufts. According to DYAR, it lives on *Mikania scandens* and produces for the pupation a large yellowish cocoon interwoven with the black hair. — The extent of the red colour on the thorax varies *nigrithorax*. very much, it may be almost quite red, but also nearly quite black, the latter form may be denominated: **nigrithorax** *form. nov.* (12 b).

sectinota. **C. sectinota** *Hmps.* (= *auge* *Druce*) (13 c) at first sight looks very much like *auge* *L.*, but it is easily distinguishable by the mostly larger black discoidal spot of the forewing and particularly by a series of lateral, triangular, black spots with metallic-blue scales on the first abdominal rings, the apex of the abdomen being also much less extensively black. Known from Mexico and Guatemala.

rubrobasale. **C. rubrobasale** *Lathy* is discernible from the preceding by its red basal part of the forewing, extending yet for some distance along the costa and inner margin. Ecuador.

entella. **C. entella** *Druce*. Head and collar are metallic blue, antennae black. Collar, thorax and abdomen above bright-red, the 3 last abdominal rings black; dorsal and lateral spots metallic blue. Ventral side black, on the 2nd and 3rd rings white. The forewings have a red basal part, veins, margins and apex are black; also the hyaline hindwings are bordered with black. Expanse of wings: 45 mm. Ecuador.

brinkleyi. **C. brinkleyi** *Rothsch.* (13 c) is a magnificent large species from Colombia (Cauca Valley). The head is black, on the forehead and vertex with metallic-blue spots; collar and thorax are metallic blue, the shoulder-covers scarlet, outside black. The scarlet abdomen exhibits dorsal and lateral rows of triangular, metallic-blue spots bordered with black; the last two rings are black. Forehips, middle hips and the whole hindlegs are scarlet, the rest of the legs blackish-brown. Antennae black with white tips. Base of the wings scarlet.

garleppi. **C. garleppi** *Rothsch.* (13 c). Exactly like *brinkleyi*, but all the red parts are here dark yellow. The thorax is yellow; the legs are blackish-brown, the forehips yellow. The bases of the wings are black. Described from Bolivia.

hector. **C. hector** *Stgr.* (13 c) differs from the following species merely by its quite unicolorously scarlet abdomen. Expanse of wings: 42 mm. Panama (Chiriqui).

zurcheri. **C. zurcheri** *Druce* (13 d) is a sexually dimorphous species: the yellow colour of the ♂ abdomen is in the ♀ a magnificent scarlet. Head, thorax and apex of the abdomen are black with metallic ultramarine-blue spots. From Costa Rica (San Carlos).

brasilicola. **C. brasilicola** *Strand* differs from the preceding by its smaller size, white spots on the head, collar and base of the shoulder-covers; but instead there are here no blue spots. Thorax also underneath black, white-spotted; also the forehips are white. The ventral valve is golden-yellow; margins of the wings and discocellular streaks are narrower black. Expanse of wings: 25 mm. Brazil (Maranhão).

galathea. **C. galathea** *Schaus.* Head, thorax and legs black; forehead, spots on the vertex, collar, shoulder-covers and forehips white. Abdomen of a deep yellow, above the last 4 rings black with a steel-blue gloss, underneath only the two last segments black. Ventral valve black. Wings hyaline with black veins, margins, apical and inner-angular spots. Expanse of wings: 29 mm. Costa Rica (Tuis).

venatum. **C. venatum** *Rothsch.* (13 d) recognizable by the yellow veins and the distal margin being likewise orange-yellow between the median veins; moreover, the costal and inner margins as well as the transverse vein are orange; only the lower median vein and the median itself, as well as apical spots and the inner angle are black. The body is orange-yellow. Forehead white, vertex and antennae black; palpi black; thorax black-spotted; on the abdomen the articular indentations, as well as lateral spots, are black. Peru.

semifulva. **C. semifulva** *Druce* (13 d). One of the smallest and neatest species, easily recognizable by the yellow veins and margins of the middle part of the wings, whilst the base, discoidal spot and distal margins are black as in the other species. Head black with a white forehead; thorax and abdomen, except the black apex, yellow. Collar and apices of the shoulder-covers black. Apparently nowhere common in Mexico (*Orizaba*, *Jalapa*, *Misantla*) and Panama.

impar. **C. impar** *Wkr.* (= *vernana* *Druce*) (13 d). One of the largest species being on the whole coloured and marked like the common *auge*. Beside double the size, the red of the abdomen is reduced to quite narrow,

small stripes at the sides of the 3 first segments reduced. The legs are quite black except the red hips, the large ventral valve of the ♂ is almost quite silvery white. Veins and margins of the wings are much broader black, particularly the middle spot is very large. Occurring in Mexico, Guatemala and Panama.

C. rubriguttum *Skinner* greatly approximates the preceding, but it also comes near the following *rubriguttum*, by the hindwings being orange-red in the basal part and distally black. Collar and shoulder-covers are orange, the rest of the thorax black, blue-spotted like the head. Abdomen black, blue-spotted; legs blackish-brown. Wings like in *auge*, but the red colour replaced by orange and the discal spot pupilled in orange. Expanse of wings: 40 mm. One specimen taken in August in Arizona.

C. cardinale *Hmps.* (13 d) is a magnificent and scarcely mistakable species owing to the broadly *cardinale*. carmine inner-marginal area of the hindwing. Body black, collar with 2 white dots, shoulder-covers striped red. The abdomen is laterally red-spotted at the first 3 rings; the dorsum exhibits one row, each of the sides two rows of white dots; the middle spot on the first abdominal ring is the largest. Apparently not rare in Brazil (São Paulo).

C. erythrarchos *Wkr.* (= *vulneratum* *H.-Schäff.*) (14 m) resembles the preceding and differs by *erythrarchos*. subdorsal abdominal spots on the 3rd ring; the red lateral spots are confined to the first ring on which we notice, instead of one dorsal, 2 subdorsal, white streak-spots; only the last rings exhibit above insignificant, small white spots. In the hindwing the inner-margin is much less extensively red. Venezuela; Brazil (Rio de Janeiro).

C. xanthistis *Hmps.* (13 e). Head black, forehead in the shape of a horse-shoe being open above, *xanthistis*. white. Antennae black with white tips. Collar black, on the shoulders a white dot. Thorax and shoulder-covers orange-yellow. Abdomen black, the first 3 rings above with orange-yellow hair, the other rings exhibit white, dorsal, lateral and sublateral spots. The wings are yellowish diaphanous with black margins, the bases of the costal and inner margins orange. Brazil (São Paulo, Santos).

C. rosenbergi *Rothsch.* (13 e) resembles the preceding from which it differs by its quite black thorax *rosenbergi*. with a white middle-spot, by the absence of the white dorsal spots on the black part of the abdomen, as well as by the yellow colour being absent at the bases of the wings, at the costal and inner margins. The ♂ has only the 2 last abdominal rings black. Ecuador, Colombia.

C. hanga *H.-Schäff.* (= *arauna* *Wallgr.*) (13 e) has a black-brown body, spots on the shoulder-covers *hanga*. and subdorsal spots on the first, 3rd and 4th abdominal rings are orange. White-coloured are the tips of the antennae, spots on the head, collar, legs and abdomen. The species is easily recognizable by the very large orange spots at the bases and inner margins of both the wings. The extreme apex of the wings is white. Occurring from Brazil as far as Argentina.

C. leuconoton *Hmps.* (13 e). Body blackish-brown; the base of the shoulder-covers and metathorax *leuconoton*. white-spotted; the first abdominal ring exhibits one large dorsal, the second 2 subdorsal, white spots; the penultimate segment exhibits orange and red subdorsal spots, the last being blue-spotted. At the base of the forewing there is a carmine spot; the distal margins and apical spot blackish-brown. Colombia.

C. melathoracia *Kaye* (13 e). Body black. Forehead and neck with bronze-green spots; similar dorsal *melathoracia*. spots of a square shape are exhibited by the abdomen the first segment of which shows subdorsal brick-red spots. From Trinidad.

C. rica *Dogn.* Body pale metallic bluish green, interrupted by black; the 1st abdominal ring is *rica*. yellow, the under surface inclusive of the legs black, the forehips white. Wings hyaline, finely bordered with black, with a black cell-spot and apical spot. Expanse of wings: 29 mm. Ecuador (Loja).

C. stryma *Druce* (26 k). Blackish-brown with carmine spots on the base of the shoulder-covers and *stryma*. 1st abdominal ring. The ends of the tarsi white. Wings hyaline, with narrow brown veins, margins, apical and discal spots. Expanse of wings: 22 mm. Known from Mexico (Orizaba) and Nicaragua.

C. gracula *Dogn.* Body black, with metallic green spots. The first abdominal ring exhibits a large, *gracula*. square, red spot, the following ones at the sides double metallic-green transverse bands. Hips and end of abdomen beneath white. The hyaline wings are bordered with black, the forewings at the base with a red basal spot; at the cell-end there is a broad black transverse band. Expanse of wings: 31 mm. Colombia.

C. lycopolis *Druce* (13 e). Body black, antennae only at the base black, otherwise orange. Head, *lycopolis*. collar, shoulders and metathorax blue-spotted, as well as the legs; the ends of the tibiae and the tarsi orange, posterior hips yellow. The abdomen being subdorsally blue-spotted exhibits on the first and last rings dorsal yellow spots, from the 2nd to 5th rings yellow lines. Ventral valve bordered with yellow, behind it sublateral, yellow spots. Wings hyaline with narrowly black veins and margins; subcostal and inner-marginal stripes orange; apical spot scarcely noticeable. Expanse of wings: 36 mm. Ecuador.

- nobilis*. **C. nobilis** Schaus. Body black, forehead, collar and thorax with metallic blue spots, on the meta-thorax a large spot of a white and blue opalescence. On the abdomen the hind-margins of the segments are narrowly yellow; at the sides there are blue transverse lines and sublateral blue spots, the 2 last rings are quite blue; the 1st ring exhibits above 2 opalescent spots, wings hyaline with black veins and margins, discal and apical spots; the base of the forewing is blue-scaled below the costa and cell. Expanse of wings: 44 mm. Costa Rica.
- cinctum*. **C. cinctum** Schaus (13 f) differs from the allied similar species by orange-yellow costal- and inner-marginal stripes, as well as by the black and white forehead, also the tips and base of the antennae are in front white. The thorax is in the middle quite black. The first abdominal ring exhibits above a white band. Venezuela (Aroa).
- gaza*. **C. gaze** Schaus approximates the following, being distinguished by the deeper orange-red colouring of the yellow parts, the first abdominal ring exhibiting a whitish band; the black and blue bands on the following rings are expanded into dorsal spots. Palpi orange and black; the thorax is black, blue-spotted. Expanse of wings: 42 mm. Peru.
- tarapotense*. **C. tarapotense** Druce (13 f). Head and thorax black; palpi, forehead and vertex yellow; collar black, margined by yellow; shoulder-covers yellow striped; abdomen black with blue subdorsal spots, segmental indentations yellow; underneath black, ventral valve margined by yellow; a band behind it yellow. Legs black and yellow. The hyaline wings exhibit narrow black margins and orange-yellow inner-marginal stripes. Peru (Tarapoto).
- simillimum*. **C. simillimum** Rothsch. (13 f) is extremely similar to the preceding; different by a yellow, not black margined collar, with a black median spot, the black thorax with a yellow band and quite orange-yellow legs. Amazon.
- steinbachi*. **C. steinbachi** Rothsch. (13 f) likewise resembles the preceding; forehead yellow, vertex black and blue; collar yellow with a black spot; the first abdominal ring quite yellow, the black bands much broader. Bolivia.
- metallicum*. **C. metallicum** Rothsch. (13 f). Head and thorax metallic bluish-green, with black margins. The abdomen is black with subdorsal and sublateral rows of metallic bluish-green spots; the first 4 segments exhibit orange segmental indentations. Legs black, with metallic greenish-blue spots. Wings yellowish hyaline, costal margin orange, margins and a large apical spot black. Bogotá; Amazon (?).
- flavicostale*. **C. flavicostale** Rothsch. (13 f) has a black body; at the base of the brown antennae a small white spot; collar with metallic blue spots; shoulder-covers yellow with black distal margins; on the black thorax a yellow middle line; the abdomen with a steel-blue reflection, on the first two segments pale-yellow, on the 3 next ones orange curled. Legs black with yellow tarsi, forehips white-spotted. Wings yellowish-hyaline, at the costal and inner margin orange. Peru.
- meridense*. **C. meridense** Rothsch. (13 f). Head and collar orange; thorax black with orange stripes; abdomen deep steel-blue with narrow, orange-yellow rings at the segments 2 to 4. On the yellowish, hyaline wings the basal half of the costal margin is orange-yellow; distal margins narrowly black. Venezuela (Merida).
- ichneumonoides*. **C. ichneumonoides** Rothsch. (13 f). Head and thorax are reddish orange, like the legs and antennae. Abdomen black; the 1st segment and transverse bands on the 2nd to 4th are orange. The wings are quite faintly yellowish hyaline with orange veins; the base, costal and inner margin and the transverse vein vermilion. Described from East Bolivia.
- flavitarise*. **C. flavitarise** Wkr. (= scintillans H.-Schäff.) (13 g). Similar to the following. Body black; forehead, margins of the collar, spots on the thorax and the shoulder-covers, sides of the thorax, small spots on the legs and posterior tarsi and narrow rings on the abdomen are yellow; metallic blue spots are noticed on the vertex, collar, thorax, forelegs, and subdorsally on the abdomen. Forehips, inner side of the femora and margins of the ventral valve white; apex of abdomen below yellow. The yellowish hyaline wings have narrow black veins and margins; the latter at the apex somewhat broader. The forewings exhibit at the base a blue spot. The marginal band of the hindwing is somewhat broader at the inner angle. Colombia; Venezuela; Brazil.
- beatrice*. **C. beatrice** Druce (= scintillans Druce) (13 g) differs from the preceding by the black, metallic blue spotted forehead; besides it is mostly larger, the wings have a more yellowish tinge and a scarcely noticeable apical spot. On the abdomen only the 3 first rings are curled orange-yellow; in the ♀ the anal apex is orange-yellow. Costa Rica, Panama. — In **jactans** form. nov. (= ab. 1. *Hmps.*) the shoulder-covers are bordered with orange; the blue of the abdomen is confined.
- guapila*. **C. guapila** Schaus. Much smaller than the preceding. The abdomen exhibits only at the 3rd and 4th segments pale reddish-yellow rings. Instead of the subdorsal blue spots there are here dorsal and lateral rows; the last segment is orange-red. Hips, anterior tibiae and posterior tarsi white. Expanse of wings: 29 mm. Costa Rica.
- baroni*. **C. baroni** Rothsch. (13 g) strikingly resembles certain species of the genus *Sarosa*. The body is jet-black with metallic blue, small spots situate subdorsally on the abdomen. The last abdominal segment and

narrow rings on the segments 3 and 4 are orange-yellow. The legs are brown, the forelegs outside metallic blue, posterior and middle tarsi curled in a cream colour. The wings are yellowish hyaline with a metallic blue basal spot; the black apical spot is very small. Ecuador.

C. salvini *Btlr.* (14 m). Black; head and thorax, collar and shoulder-covers, legs and sides of the *salvini*. abdomen with large, uncommonly brilliant metallic blue spots. Forehips white. Ventral valve bordered with white. Abdominal end orange. Wings yellowish hyaline with fine black veins and margins; the forewings exhibit a large apical spot and blue basal spot. Expanse of wings: 40 mm. Panama (Obispo).

C. lucens *Dogn.* (10 a) differs from the preceding by the absence of the orange colouring of the abdo- *lucens*. minal end; the 3 first rings exhibit above finely white-bordered posterior margins. Colombia (Popayan).

C. bricenoi *Rothsch.* (13 g) looks like a *Gymnelia*. Head orange with a black spot on the forehead; *bricenoi*. collar and thorax orange and black; the abdomen is black, on the first 4 segments subdorso-laterally with deep orange bands; above with metallic blue spots, on the 3 last segments also laterally. Palpi, antennae and legs black, forehips orange. On the wings only the apex of the forewing, the proximal margin and fringes are black, the costal margin and a basal inner-marginal spot yellow. Venezuela (Merida).

C. carabayanum *Rothsch.* (13 g) greatly resembles the preceding species, from which it differs by *carabaya-* the more golden yellow, black-margined collar and shoulder-covers, and by the quite golden yellow palpi and *num*. legs; the black abdomen exhibits above on the 4 first segments, laterally also on the fifth, golden yellow bands; the 4th and 5th segments show metallic greenish-blue dorsal spots, the last 3 rings broad metallic bluish-green bands. The wings are not so yellowish as in the preceding species; the base of the proximal margin in the hind-wing yellow. Peru.

C. viridicingulatum *Rothsch.* (13 g). Easily recognizable by the dark orange-red abdomen with metallic *viridicingu-* green bands. Head, collar and shoulder-covers black, with orange bands and metallic green spots; thorax *latum*. black with green spots. Legs brown, tarsi white, forehips metallic green. The yellowish hyaline wings exhibit fine blackish-brown margins; at the base of the forewing is a metallic green spot. Ecuador.

C. quinquepuncta *Heyl.* Jet-black; spot on the forehead, front part of the palpi, shaft of the antennae *quinque-* in the middle, and spots on the prothorax white. Collar in the middle grey; metathorax blue-spotted. The *puncta*. 1st abdominal ring exhibits dorsal and subdorsal white spots bordered with blue, the second ring subdorsal ones; the other rings with subdorsal blue spots, the last rings also with sublateral ones. Ventral valve white. Wings hyaline with black veins, base, margins and discal spot. Expanse of wings: 32—35 mm. Brazil (São Paulo).

C. beata *Btlr.* (13 h). The body is orange-red; vertex, collar, shoulder-covers, meso- and meta-thorax *beata*. with metallic bluish-green spots bordered with black. The abdomen exhibits black transverse bands with metallic bluish-green subdorsal spots; the under surface of the first rings is whitish. Palpi, antennae and legs are black, the latter with bluish-green spots. Wings slightly yellowish with a small green basal spot. Panama; Colombia; Brazil.

C. hampsoni *Klages.* Differing from the next species by the following marks: palpi quite orange; *hampsoni*. forehips in the ♂ white; anterior margin of the 4 first abdominal segments above narrow whitish, exhibiting for the rest subdorsal black, blue-pupilled spots which are usually flown together into transverse bands on the anterior rings. Expanse of wings: 34—48 mm. Venezuela.

C. nigricornis *F.* (= *stretchii* *Btlr.*) (13 h). The head is yellow, on the vertex black with blue spots; *nigricornis*. palpi with black terminal joints; collar and shoulder-covers yellow and black striped. Thorax above black and blue spotted, beneath with yellow, in the ♀ also above with yellow spots. Abdomen yellow with black transverse bands being subdorsally blue-spotted. In the ♀ these are narrower than in the ♂. Wings yellowish hyaline with very narrow blackish margins and small apical spots. Costal and inner margins in the ♂ faintly yellow, in the ♀ intensely yellow. Colombia, Venezuela.

C. sephela *Druce* (13 g) differs from the preceding by a white-spotted first abdominal ring, much *sephela*. narrower transverse bands on the other segments with scarcely noticeable, small blue spots, the last rings are quite yellow. Costal and inner margin are orange. Ecuador.

C. villia *Druce* (13 h). The body, inclusive of the antennae and legs, is brownish orange-yellow; in *villia*. the neck two black dots; collar black, bordered with yellow. The margins of the abdominal segments are finely bordered with yellow and black; the abdomen exhibits small, subdorsal, metallic silvery-blue spots. Wings yellowish hyaline, only the fringes are black. Expanse of wings: 40 mm. Differing from the similar *sephela* chiefly by its larger size and the absence of the white basal spot on the abdomen. Peru.

C. stuarti *Rothsch.* (13 h) differs from the preceding species by the black margins and apical spots *stuarti*. of the wings, the black abdominal rings being also much broader. From Iquitos.

- fenestrata.* **C. fenestrata** *Drury* (= *steropes* Göze, *rubripeda* Lucas) is presumably the largest *Cosmosoma*, with an expanse of 62 mm. The body is black, palpi, legs and venter scarlet. The black wings exhibit a hyaline spot in the cell-end and a larger one below it, as well as a curved row of spots behind the cell between the lowest subcostal vein and the lower median vein. Hindwings whitish hyaline, costal margin, cell, veins and marginal band black. Jamaica and Cuba.
- seraphina.* **C. seraphina** *H.-Schüff.* (13 i). Head black, thorax carmine with 2 black spots on the mesothorax. Abdomen black with red lateral stripes and 2 white dorsal stripes on the first segment. Wings hyaline with black veins, margins, apical and inner-angular spots, as well as red costal- and inner-marginal stripes. Expanse of wings: 26 mm. Amazon.
- tigris.* **C. tigris** *Schaus* (13 h). Body black, palpi in front orange. Forehead, vertex, collar and metathorax blue-spotted. Collar, shoulder-covers and thorax with orange spots. Breast and legs with orange stripes. The abdomen exhibits above orange spots which turn to broad bands on the 4th and 5th rings. On the first 3 rings orange lateral spots, on the others lateral and sublateral blue macular series. Wings hyaline with black veins, broad margin and apical spot; on the forewings the subcostal area and 2 stripes at the base of the inner margin are orange, on the hindwing the inner-marginal part is the same. Expanse of wings: 36 mm. Venezuela.
- cermena.* **C. cermena** *Dogn.* (13 i). Front body black with metallic blue spots; shoulder-covers yellow, bordered with black. The 4 first abdominal rings are above yellow with a dorsal black, blue-pupilled spot; the rest of the abdomen is black, with dorsal and lateral, metallic bluish-green spots. Forelegs black with bluish-green hips, middle- and hind-legs black with yellow tarsi. Antennae black with white tips. Wings like in *tigris*. Ecuador (Loja).
- dubium.* **C. dubium** *Rothsch.* (13 i). Head and thorax are black, with metallic blue spots, the shoulder-covers of a brilliant yellow; the abdomen is yellow, the 3 last rings black with subdorsal blue spots; the other segments exhibit triangular black, blue-pupilled dorsal spots; the spot on the first ring is larger than the others. The forehips are metallic blue, the legs blackish-brown, except the posterior tibiae and tarsi which are yellow. Costal and inner margins are yellow, also the distal margin is partly yellow. Jamaica.
- mathani.* **C. mathani** *Rothsch.* Head metallic blue, antennae black with a white apex, palpi black; thorax black, with metallic blue spots, beneath golden orange and black. Abdomen golden orange, the first and the 4 last rings above black; dorsal and lateral metallic blue longitudinal stripes in the ♂ run over the whole abdomen, in the ♀ only on the black rings. Wings hyaline with black veins, margins and apical spots. Length of forewings: ♂ 21, ♀ 24 mm. Cundinamarca.
- contractum.* **C. contractum** *Wkr.* (13 i). This and the following species resemble each other very much. The body is black; forehead and vertex, collar and shoulder-covers, as well as metathorax and base of the forewing with metallic blue spots; the abdomen shows on the 3 first rings bluish-green silvery subdorsal and sublateral spots and on the 2 last segments blue subdorsal spots. A characteristic of the species is that the orange subcostal stripe extends into the black apex of the forewing and the orange colour extends at the inner side of the apical spot down as far as about the lower radial; proximal margin broad orange; the wings themselves are somewhat yellowish. The teeth of the antennae orange. Brazil.
- gemmatum.* **C. gemmatum** *Btlr.* (13 i) is easily separable from the preceding very similar species by the shorter orange costal-marginal stripe which does not extend into the apex of the wing, which is here quite black, inwardly not with an orange tint. Besides the metallic blue abdominal spots are large and more intense, and are on all the segments, only on the 4th they may be absent. The ♂ exhibits on the ventral side of the 3rd segment 2 yellow spots. Panama, Colombia, Venezuela, Peru (Cuzco). The species seems to vary considerably. — f.
- xanthocera.* **xanthocera** *Hmps.* (13 k) which was originally described as a species and in fact looks very differently, according to Klages who often found it in Venezuela, also in copula with *gemmatum*, is only a form of it; both have the same habits. The palpi and antennae are orange, the collar orange with blue and black spots, the shoulder-covers with orange-stripes; also the thorax is posteriorly spotted orange; the abdomen exhibits on the 3 first segments dorsal and lateral orange spots, the 4th and 5th segments with orange bands. Occurs in Venezuela as well as in the Amazon District.
- deyrollei.* **C. deyrollei** *Wkr.* (13 i). The blackish-brown body exhibits white lateral spots on the abdomen and dorsal spots on the 3 penultimate rings. The yellowish diaphanous wings show narrow black margins as well as orange-yellow costal- and inner-marginal streaks. Hitherto known only from Brazil (Rio Grande do Sul and Sa. Catharina).
- saron.* **C. saron** *Druce* (= *meres* Druce) (13 k). Body black, forehead white, vertex metallic blue; thorax with blue spots. Abdomen with subdorsal and sublateral blue macular series and small subdorsal orange spots on the 1st and 4th rings. Wings yellowish hyaline, veins and margins, as well as apical spot black; the forewing with a golden yellow subcostal stripe and basal inner-marginal spot. Expanse of wings: 30 mm. Panama (Chiriqui).

C. cinctutum *Schaus* differs from the preceding species by orange, black-bordered collar and shoulder-covers; the first abdominal ring is quite orange, above parted only by a narrow black dorsal line; dorsally there are also blue spots, dying away on the 3rd and 4th rings. Legs orange, with some black stripes. Wings not so yellowish hyaline, otherwise like in *saron*. Costa Rica (Juan-Vinas). *cinctutum*.

C. bolivari *Schaus* (13 k) is a small species with a black head and thorax; collar and shoulder-covers orange. The abdomen is orange; the first segment exhibits a black dorsal spot, the 3 next ones are above quite black, narrowly margined by orange, the 5th is orange, narrowly bordered with black, the next 2 are again black, the anal apex orange. The costal margin of the hyaline forewings is orange, the margins and apical spots otherwise black. From Ecuador (Bolivar). *bolivari*.

C. plebecula *Dogn.* differs from the preceding by its entirely yellow thorax and the absence of the orange subcostal stripe. Expanse of wings: 24 mm. Colombia. *plebecula*.

C. chiriquensis *Rothsch.* (13 k). The head is black, thorax and abdomen golden-yellow, the latter above on the 2nd and 3rd segment black, also the two last rings are black. Legs and antennae are black. Base of forewing yellow, bordered with black. Panama (Chiriqui). *chiriquensis*.

C. corvicum *Dogn.* Body black, tips of antennae white. Head, collar and thorax with metallic green spots. The 2 first abdominal rings exhibit lateral large metallic green spots, the last rings exhibit a dorsal green lustre. Venter black, the first ring green, the 2 following ones white-striped. Wings hyaline with black veins broad margins and apical spots, and a large discal spot on the forewing. Expanse of wings: 26 to 33 mm. Bolivia (Corvico). *corvicum*.

C. pheres *Cr.* Like the following, but somewhat smaller and the abdominal spots of a pure metallic blue; the white lateral spots on the 2nd ring are absent. Expanse of wings: 28 mm. Brazil (Rio de Janeiro). *pheres*.

C. metallescens *Mén.* (= *pheres* var. *Wkr.*, *chalcosticta* *Btlr.*) (13 k). Black, head, thorax and abdomen on the dorsum and on the sides with metallic bluish-green spots. Forehead, forehips and ends of tarsi white. Distinguished from the similar species by the intense golden green reflection of the metallic spots, as well as by a white spot at the sides of the 2nd abdominal segment, from *xanthostictum* (13 l) particularly by the white forehead. From Mexico, Panama, Amazon, Pará. *metallescens*.

C. batesi *Btlr.* (13 k) has a unicolorously orange-yellow body; the palpi are either yellow or black, or yellow with a black terminal joint; the forehead is white, vertex and antennae black. Bases of the wings orange, which colour usually extends for a short distance along the costal and inner margin, but may also be confined to a minute spot at the base. Brazil (São Paulo). *batesi*.

(?) **C. bromus** *Cr.* Head, thorax and abdomen are dull yellow, wings hyaline with black veins and margins, as well as large apical spots. Expanse of wings: 36 mm. — This species originally described from Surinam perhaps does not belong at all to the genus *Cosmosoma*. *bromus*.

C. melanopera *Hmps.* (13 k) has an entirely scarlet body, only the head and anal segment are black, the forehead white. The forewings exhibit at the base a small red spot. Described from Bolivia (San Jacinto, Bueyes), but it is before me also from Manaos, Amazon. *melanopera*.

C. coccinifera *Dogn.* (13 l). This tiny species has a jet-black body with a blue lustre; the forehead is white; collar and shoulder-covers are of a deep scarlet, finely bordered with black. The abdomen on the first 5 rings exhibits large triangular scarlet subdorsal spots; the ventral side of the first 4 rings and the hips are white. Before me is only a male specimen; the description referring to a ♀ mentions besides a series of sublateral red spots on the 4 first abdominal rings; the forehead is said to exhibit a green reflection. East Colombia (Medina). *coccinifera*.

C. phoenicophorum *Dogn.* (13 l) presumably is the smallest species with a blackish-brown body; collar, lateral stripes on the 4 first abdominal rings, as well as the inner-marginal area of the hindwing are rosy-red, also a narrow basal inner-marginal stripe on the forewings. The wings are hyaline, with very broad brown distal margins and a very large round discal spot, also the bases of the wings are brown. Colombia (Medina). *phoenicophorum*.

C. colona *Schaus.* Body black, tips of antennae white. Forehead, collar and shoulder-covers are of a deep metallic blue lustre. The abdomen exhibits subdorsal, blue, transverse streaks, on the first ring white lateral spots; the 2 last rings are red. The wings are hyaline with black veins, margins and apical spots. Expanse of wings: 33 mm. Costa Rica. *colona*.

C. plutona *Schaus* (13 l). Head and thorax black, vertex and collar blue-spotted; abdomen above deep carmine. The hyaline wings have rather uniformly broad black margins; the subcostal space as far as the middle-spot hyaline. Brazil. *plutona*.

- determinatum.* **C. determinatum** Btlr. (13 l) has a black head and thorax; forehead, vertex, collar, metathorax and legs show metallic blue spots; the abdomen is orange-yellow, the 3 last segments black, with lateral blue spots; the base of the costal margin exhibits a small blue spot. Distinguishable from the many similar species by the absence of small white spots on the thorax and bases of the wings. Colombia (Cundinamarca).
- xanthostictum.* **C. xanthostictum** Hmps. (= *metallescens* Druce) (13 l) differs from the very similar *metallescens* by its mostly larger size, much more extensive black with metallic blue scaling at the base of the forewing, the nearly quite white tarsi and, above all, by the bright metallic blue, not white forehead. The metallic spots, particularly of the two first abdominal segments exhibit an intense orange golden lustre. In the ♀ the 3 last abdominal rings are beneath covered with a thick, orange-yellow fur. Mexico (Tabasco, Misantla [October]), Guatemala, Panama.
- durea.* **C. durca** Schaus (= ? *nigripes* Heyl.) (13 l). Body black, head, collar, shoulder-covers and thorax with metallic blue spots, also the sides of the abdomen. The ends of the tarsi are white. At the base of the forewing a metallic blue spot. From the following, very similar, larger species it differs by the laterally blue-spotted abdomen and the black apex of the forewing being only moderately broad. Brazil (Sao Paulo).
- elegans.* **C. elegans** Btlr. (14 a) differs from the preceding, very similar species by the quite unicolorously black abdomen without any lateral blue spots and the very much broader black apex of the forewing, the proximal borderline of which stands almost vertically on the costal margin. Brazil (Espiritu Santo).
- pellucidum.* **C. pellucidum** Lathy resembles *Pheia sperans* (12 e). Body black, forehead and forehips white, collar, shoulder-covers and thorax blue-spotted. The first 5 abdominal rings exhibit red sublateral stripes, the venter is white except the 2 last rings. Wings hyaline with broad black margins and apical spots. Brazil.
- oratha.* **C. oratha** Druce (14 a). Black, forehead white; collar and metathorax blue-spotted, shoulders with carmine spots. Legs blue-striped, forehips white-spotted. The abdomen exhibits obsolete blue subdorsal stripes, on the last ring a dorsal blue spot, the first ring exhibits lateral carmine spots. The forewings are black, at the base with blue dots, and with hyaline spots in and below the cell and 3 or 4 smaller spots behind the cell; the hindwings show hyaline spots behind and below the cell. On the under surface all the wings are roughly scaled towards the margins, like in the 2 following species. British Guiana.
- orathidium.* **C. orathidium** Druce (14 a) differs from the preceding by white, instead of red shoulder-spots, otherwise very similar. Nicaragua.
- crathidium.* **C. crathidium** Rothsch. (14 a) differs from the preceding species by the wings being as usually extensively hyaline. Habitat unknown.
- protus.* **C. protus** Druce (14 a). Head, thorax, abdomen and legs black with metallic blue spots, shoulder-covers orange-yellow, antennae black with white tips. Forewings at the costal and inner margin, the base and in the angle of the rise of the median veins and of the lower radial golden orange; this latter spot is coherent with a similar one at the inner angle. The apex of the hindwing exhibits on the under surface peculiar grey rough scaly hairs. This easily recognizable species has hitherto only been found in Mexico: Jalapa, Orizaba (October).
- festivum.* **C. festivum** Wkr. (= *aleus* Schaus) (14 a). This smaller, sexually dimorphous species shows on the black head and abdomen metallic blue spots, on the collar and shoulder-covers orange-brownish spots. On the forewing the base, costal and inner margin are dark orange-brown. The black of the apical spot and of the inner angle, which in the ♂ is expanded to a large spot being connected with the middle spot, shows a brownish admixture. The border of the hindwing in the ♂ is more than twice as broadly black as it is in the ♀. Widely distributed and common in Mexico, Guatemala, Honduras, Costa Rica.
- centralis.* **C. centralis** Wkr. (= *bura* H.-Schäff.) (14 a) is easily recognizable by the triangular, orange spot between the lower median vein and the lower radial of the ♂ forewing, the orange colour of the inner margin extends also for some distance, before the black border, up the distal margin. The body is black with metallic blue spots on the forehead, vertex, collar, thorax, legs and abdomen. The black-margined shoulder-covers and a lateral spot at the base of the abdomen are orange. The ♀ is without the orange spot of the forewing, but the venter is orange, instead. Distributed from Panama through Brazil as far as Paraguay.
- zelosa.* **C. zelosa** Dogn. (14 b) is presumably only a profusely yellow tinged form of *centralis*. Head black, on the forehead and hindhead with metallic bluish-green scales and yellow hair; shoulder-covers orange-yellow, bordered with black. The 4 first abdominal rings are orange-yellow, black-curved and with dorsal and lateral bluish-green spots; the other rings black with bluish-green spots, anal end with yellowish hair. Legs black with yellowish ends of the tarsi. Wings hyaline with black veins and, particularly on the hindwings, broad distal margin. Bases of both wings, costal and inner margin of the forewing, as well as the proximal bordering of the distal margin of the forewing from the inner angle as far as the middle radial upwards orange; in

the ♀ there is in the angle between the lower median vein and the lower radial a triangular, orange-yellow spot bordered with black. Colombia (Micay; Rio Aguaca).

C. thoracicum *Schaus.* The neck and thorax are ochreous orange, the other part of the body is black, *thoracicum.* on the forehead, the first abdominal ring and at the sides of the other rings blue-spotted. The forewings are orange at the base; the margins and apical spots are broadly black, as well as the space between the lower median veins and near the cell also between the upper median vein and the lower radial. Expanse of wings: 24 mm. French Guiana.

C. sicula *Dyar* approximates *centralis* (14 a). The body is quite black, blue-spotted, on the collar *sicula.* and shoulder-covers single orange-red scales. The hyaline, black-veined wings are at the costal and inner margin striped in an orange-red, the distal margin is black, at the apex very broad; the discal spot very narrow; the space between the median veins is in the ♂ black with orange-red scales, as well as the extreme base between the upper median and lower radial vein. Expanse of wings: 27 mm. Described according to 1 ♂ from Venezuela.

C. teuthras *Wkr.* is one of the most common species being distributed almost through the whole *teuthras.* of Tropical America from Mexico to Argentina, immediately recognizable by the red, black-margined discoidal spot. The black, blue-spotted abdomen exhibits at the base lateral red spots. According to the extent of the red costal- and inner-marginal streaks different forms are denominated. In the name-type the inner-marginal red only extends somewhat beyond the middle. — **cingulatum** *Btlr.* (14 b) is the name of the form flying the *cingulatum.* most frequently in Mexico, Yucatan, Guatemala, Costa Rica, and Panama, in which the very bright scarlet at the inner margin extends as far as the inner angle. — The Brazilian form **erubescens** *Btlr.* (14 b as *teuthras*) *erubescens.* is somewhat smaller and the red discoidal spot much smaller, the red more intense, extending at the inner margin as far as the inner angle. — In **lignicolor** *Rothsch.* (14 b) from Ecuador all the red parts are yellow, the *lignicolor.* black ones being of a wooden-brown colour, the latter parts being at the same time much more extensive than in the name-type; the wings are also a little shorter and broader. — **nigrescens** *Rothsch.* (14 b) is a rare form *nigrescens.* from Colombia, in which the costal margin and middle spot are entirely black, without any trace of red. — **restrictum** *Btlr.* (14 b) may be considered as the transition to it; here the red of the costa is already greatly *restrictum.* reduced; the red inner-marginal streak does not reach the middle of the inner margin. Described from Brazil (Santarem).

C. cruenta *Perty.* Body black, tips of antennae white; vertex and collar with white dots, shoulder- *cruenta.* covers with carmine stripes; the abdomen exhibits on the 3 first rings subdorsal, broad, carmine bands; the other rings dorsal, lateral and sublateral white dots. The hyaline wings are greatly distinguished by not only the costal- and inner-marginal stripes being suffused by red, but also the distal margin and apical spot, also on the hindwings. Expanse of wings: 34 mm. Amazon.

C. caecum *Hmps.* (= *impar* *Druce* pr. p.) (14 c). Exactly like the *teuthras cingulatum* *Btlr.*, only *caecum.* the discoidal spot is entirely black, rarely with a reddish brightening in the middle. The red colour is generally duller, more brownish. Mexico, Guatemala, Costa Rica, Panama.

C. parambae *Rothsch.* (14 c) greatly approximates the preceding and differs by its brown, not orange- *parambae.* red costal and inner margin, by orange-yellow, not red colour at the base of the hindwing and abdomen, by the more brown thorax, by the black distal margin of the forewing being very narrow between the upper median and lowest radial vein but growing very broad between the upper median vein and the inner angle. Besides the species is much smaller. Ecuador.

C. telephus *Wkr.* (= *coccineum* *Btlr.*, *pyrrhostethus* *Btlr.*) (14 c) differs from the very similar *caecum* *telephus.* by its entirely red collar and shoulder-covers, as well as the entire absence of the discoidal spot. Widely distributed from Colombia to Argentina.

C. achemon *F.* (= *tyrrhene* *Hbn.*, *voltumna* *Druce*) (14 c). Head black, on the forehead and vertex *achemon.* metallic blue, antennae white at the tips; thorax orange-red, beneath black; abdomen black with an orange-red dorsal stripe being in the ♂ narrow, in the ♀ much broader, and subdorsal metallic blue spots. Base of forewing orange-red, which colour extends at the costal and inner margin almost to the apex; in the ♂ between the lower median and lower radial vein a red spot bordered with black, being absent in the ♀. — In f. **bolivarensis** *Klages* *bolivarensis.* all the red colour of the body is removed by black; the black colour and thorax are covered with metallic blue spots; only the shoulder-covers occasionally show red stripes; the black abdomen, beside the subdorsal spots, exhibits very large metallic blue sublateral spots which are only very little developed in the name-type. Also the inner-angular spot in the ♂ is quite black. — The nomenclatural form flies in Jamaica and Hayti, Venezuela and Brazil; the black form to which perhaps also *remotum* is allied has hitherto only been found in Venezuela (Bolívar and Suapure).

C. achemonides *Dogn.* Very near to the preceding, but larger. Antennae quite black. The abdomen *achemoni-* *des.* is more uniformly suffused by blue; the red middle stripe is somewhat expanded on the middle rings; marginal band and apical spot of the wings are more orange-yellow, and brownish only close before the apex. Expanse of the wings: 29 to 31 mm. Peru.

- hypocheilus*. **C. hypocheilus** *Hmps.* (14 c) differs from the preceding species by the red inner-marginal stripe not extending as far as the middle; the abdomen is orange-red, with subdorsal black longitudinal stripes exhibiting metallic blue spots and approaching each other very closely towards the base and towards the last segments; the last rings quite black; also in this species the black embedding between the lower median and radial vein of the ♂ is very much reduced or altogether absent in the ♀. St. Vincent.
- perfenestratum*. **C. perfenestratum** *Dyar.* Head black, on the forehead and vertex with metallic blue spots. Thorax orange-red, beneath black; legs black with blue spots. Abdomen black with a red dorsal stripe reaching neither to the thorax nor to the anal end, and with subdorsal blue spots. Wings hyaline with black veins and margins; at the base of the forewing an orange-red spot and similar stripes at the costal and inner margin. Discal spot orange-red, traversed by black veins; a spot of the same colour fills up the space between the median veins and the lower radial; the marginal band which grows much broader towards the apex is almost quite orange-red traversed by black veins. Hindwing at the base likewise red and the black margin proximally also red. According to a ♂ without the habitat and size being stated.
- admotum*. **C. admotum** *H.-Schäff.* (14 d) differs from *achemon* by black-bordered shoulder-covers and the absence of the red dorsal stripe on the abdomen. — The red-striped inner-angular spot between the median veins in *confinis*. the nomenclatural form is quite black in f. **confinis** *H.-Schäff.*; the ♀ is without this spot. Expanse of wings: 32 to 36 mm. Widely distributed from Mexico to Brazil.
- anoxanthium*. **C. anoxanthium** *Druce* approximates *confinis*; but the thorax is quite black, only the collar and foremost prothorax are orange. Head metallic blue, antennae black with white tips; the abdomen is only at the base and laterally blue-spotted. Venezuela.
- consolatum*. **C. consolatum** *Wkr.* (14 d) from the same difficult group as the preceding is recognizable by the subcostal space being only for a short distance orange, the inner margin is black as far as the base. The head is black with metallic blue spots, the thorax orange-red; the black abdomen exhibits subdorsal and sublateral rows of metallic blue spots. Brazil.
- remotum*. **C. remotum** *Wkr.* (14 c) resembles *C. centralis* (14 a), at the abdomen the orange basal spot is absent, whereas it exhibits a second, sublateral, metallic blue macular series. The spot being in the ♂ situate between the lower median and radial vein is blackish-brown and is broadly coherent with the inner angle. The inner margin of the hindwing is without any orange colouring, black. Venezuela.
- eumelis*. **C. eumelis** *Druce* (14 d) has a black, blue-spotted body, on the shoulder-covers orange stripes. The wings are slightly yellowish hyaline, with narrow black distal margins, the costal and inner margin orange; this colour extends in front of the black distal margin yet for some distance downwards and upwards. Ecuador, Brazil, Bolivia.
- annexum*. **C. annexum** *H.-Schäff.* (14 d) likewise greatly approximates *centralis* (14 a), being distinguished by the absence of red on the base of the hindwing as well as by its entirely black thorax. The orange-yellow colouring of the costal margin expands towards the apex and terminates with the upper radial vein broadly into the black apical spot. The orange spot between M² and R³ is somewhat coherent with the inner angle. — The species is hitherto known only from Brazil (Rio de Janeiro, São Paulo).
- ethodaea*. **C. ethodaea** *Druce* (= *patagiata* *Dyar*) (14 d). This magnificent species deviates somewhat from the other *Cosmosoma* and, according to its exterior, it would indeed quite well fit to *Autochloris* where DYAR placed it as *patagiata*. Head black with a white forehead, on the vertex blue. Antennae black, beneath at the base, and at the apex white. Behind the eyes an orange-yellow ring. Collar metallic blue, shoulder-covers and thorax orange with black margins, beneath black with white spots. Abdomen black and metallic blue, the first 5 segments above with orange transverse bands; the first segment exhibits a subdorsal white spot. The 2nd segment is beneath white, which colour, however, is covered in the ♂ by the large black ventral valve. Legs black with a metallic blue scaling at the tibiae. Wings yellow diaphanous, margins and veins black. Costal and inner margin orange. On the hindwing the black of the anal angle is very extensive and united with the discoidal spot. Hitherto only known from Mexico (Atoyac; Vera Cruz; Misantla), where it is apparently not rare.
- advena*. **C. advena** *Druce* (14 d). Head black with small whitish spots. Thorax orange-red, above black. Abdomen black with brick-red subdorsal stripes being broad at the base, but growing quickly narrower, the 3 last segments quite black. Fore- and hindwing with a little orange-red at the base of the inner margin. Apparently flying all the year round in Mexico (Jalapa, Orizaba, Misantla); found also in Guatemala.
- scita*. **C. scita** *Wkr.* (= *hilaris* *Wkr.*) (14 d). Head, thorax and abdomen orange-yellow; vertex, collar and metathorax black, blue-spotted; shoulder-covers bordered with black. The abdomen exhibits on each

segment a black, subdorsally blue-spotted transverse band. The yellowish hyaline wings exhibit a large black apical spot in contradistinction to the following species. Amazon.

C. vesparia *Perty* (= *odyneroides Wkr.*). Head and thorax yellow, vertex, collar and thorax blue *vesparia*. and black spotted and striped. Abdomen orange-yellow with black articular lines and subdorsal rows of blue spots, the 4 first rings anteriorly bordered with white. Wings yellowish hyaline with fine black veins and margins. Expanse of wings: 34 mm. Amazon.

C. analicinctum *Rothsch.* (14 e) is one of the smallest species. The whole body is deep orange, the *analicinctum*. head and thorax somewhat lighter yellow; antennae and last abdominal segment black. The legs are brown, hips and tibiae yellow. $\frac{3}{5}$ of the costal margin hyaline, veins and margins black like the apical spots of both wings. Peru, taken in March and November at an altitude of 2 to 3000 ft.

C. brasiliense *Rothsch.* (14 e). The body of this small species is orange except the black head and *brasiliense*. the two last black abdominal rings. Legs and antennae are brown, forehips and ventral valve white. Brazil (Sa. Catharina).

C. impudicum *Schaus* (14 e) is perhaps only to be considered as a form of *pudica*, for it only differs *impudicum*. by the quite yellow abdomen without a black anal end. It flies in Costa Rica (Juan-Vinas, El-Sitio), and is also common in Mexico (Mexico, Orizaba, Misantla, Coatepec).

C. pudica *Druce* (14 e). Head black, forehead white, thorax and abdomen light yellow, legs and *pudica*. abdominal apex black. Forewing at the base yellow. Costa Rica.

C. nelea *Möschl.* (14 g) differs from the preceding by its black collar, white hips, brown legs and 3 *nelea*. black terminal segments on the abdomen; besides, the neck and the costal base of the forewing exhibit white dots. Expanse of wings: 36 mm. Surinam.

C. lemoulti *Rothsch.* Head and thorax brown, shoulders and abdomen orange, the two last segments *lemoulti*. black; breast and legs orange, the outside of the hips, femora and tibiae light brown. The forewings are yellowish hyaline, the veins and a large spot above the inner-marginal vein orange; the base, costa, inner margin, apical and discal spot broadly black. On the hyaline hindwings the basal third is orange, the border broad black. Expanse of forewings: 12,5 mm. Cayenne.

C. galbanum *Schaus*. Palpi, forehead and antennae brown; vertex black. Neck, thorax and abdomen *galbanum*. yellow; the last segment black being dorsally somewhat continued on the penultimate one. Legs light brown, hips yellow, posterior tarsi reddish-yellow. Wings hyaline, at the base yellow, bordered with black; veins, margins, apical and inner-angular spot black. Expanse of wings: 33 mm. Costa Rica.

C. evadnes *Cr.* (14 e). The body is unicolorously orange-yellow; only the antennae and legs are black. *evadnes*. The hyaline wings have rather broad margins and veins, apical and discal spots. Expanse of wings: 30 mm. Surinam.

C. apenninum *Druce* is an easily recognizable species. Head, antennae and palpi black, collar and *apenninum*. neck yellow, thorax black. Abdomen yellow, black-curved, anus black. Legs black. Forewing hyaline with a black apex; a broad, yellow, hyaline band extends from the cell-end to the apex. South East Peru.

C. dorsicinctum *Dogn.* Palpi, head and antennae black; collar yellow, shoulder-covers yellow, at *dorsicinctum*. the apex black. Thorax yellow, in the middle black. Abdomen yellow, with dorsal black bands and subdorsal black spots. In the ♂ the yellow colour is of a deeper orange, the prothorax blackened, the subdorsal black abdominal spots reduced, the 2 last rings quite black. Wings hyaline with black veins, margins and large apical spots, at the costal base yellow. Expanse of wings: 25 to 29 mm. East Colombia.

C. biseriatum *Schaus* (14 e) is one of the largest species with particularly broad black margins of *biseriatum*. the wings and a thick, rounded discal spot, at the base with orange spots. Head and collar are black with metallic blue spots, metathorax black with a blue spot, shoulder-covers orange, black-margined. The abdomen is on the first rings orange with lateral, large, black spots with metallic blue scales, which are more or less connected over the dorsum; the last rings are quite black and blue. Hitherto only known from Ecuador.

C. dorsimacula *Schaus* (14 f) exhibits an orange yellow thorax and abdomen; head, borders of shoulder- *dorsimacula*. covers, metathorax, 4 or 5 dorsal spots on the abdomen, and the abdominal apex are black, as well as the legs; forehips white-spotted. The hyaline wings exhibit broad black margins and a thick black discal spot. Only from Ecuador.

- regestum*. **C. regestum** *spec. nov.* (14 f) differs from the preceding species by its considerably smaller size, quite orange-yellow head and collar; palpi and antennae black; shoulder-covers orange with a narrow black middle streak; hips orange, forelegs and middle legs otherwise blackish-brown, hindlegs orange, the distal end of the femur and the proximal end of the tibiae above black. Abdomen orange, the two last segments black; the others exhibit a dorsal row of spots, and a double lateral one on each side of the middle rings. Wings hyaline; base of the forewings and subcostal space as far as the black apical spot, as well as the extreme inner-margin orange; the space between the latter and the inner-marginal vein black. Colombia (San Antonio, 1800 m), 1 ♂ taken by the light at night-time (FASSL leg.). Type in Coll. SEITZ.
- exsors*. **C. exsors** *spec. nov.* (14 f) is smaller and neater than the preceding, with broader and shorter wings; differs by its black head, the shoulder-covers being bordered with black distally and at the apex, by a more intensely orange-red ground-colouring, larger black dorsal spots, only one lateral row of black spots. On the wings only the base is orange-red, the subcostal space faintly yellowish hyaline, the proximal margin quite black. Another distinguishing mark is the cell-fold on the forewing running here separately and above the middle radial, whereas in *regestum* it is shortly behind the cell united with this. Described according to 1 ♂ of the Coll. SEITZ from Colombia (Sosomoco).
- notosticta*. **C. notosticta** *Dogn.* Head orange; vertex, palpi and antennae black; collar and shoulder-covers orange, the latter at the base black. Abdomen orange with dorsal and subdorsal rows of spots. Anal-end above, the 2 last rings beneath black; legs black and orange, hips orange. Wings hyaline with black fine margins and veins, apical spot and angled discocellular; base and subcosta orange. Expanse of wings: 27 mm. Colombia (Aguaca Valley) in August.
- citrinum*. **C. citrinum** *Rothsch.* (14 f) without the patria being stated, from the Coll. FELDER at Tring, is very easily recognizable by the peculiarly brownish apex of the forewing, being densely dusted with yellow. Head, palpi and antennae are black, the rest of the body yellow, on the dorsum spotted black; at the base of the forewing there is a yellow spot. The species resembles *Is. monticola*.
- juanita*. **C. juanita** *Neum.* Head and thorax black, palpi yellowish; shoulder-covers bordered with white. Legs red, hips white, abdomen brilliant red, the first ring and the last ones black. Wings hyaline, veins and very broad margins and apical spots black. Expanse of wings: 23 mm. Cuba.
- tengyra*. **C. tengyra** *Wkr.* (= *fulviventris Mén.*) (14 f). Head and thorax blackish-brown; forehead, shoulders, thorax, forehips and legs white-spotted. Abdomen yellow. Wings hyaline with blackish-brown veins and margins. Forewing with 2 white basal dots. Expanse of wings: 32 mm. Amazon (Pará).
- hercyna*. **C. hercyna** *Druce* (14 f) differs from the many similar species by the unicolorously orange-yellow abdomen; the front body is quite black. Distributed from Mexico across Nicaragua as far as Panama (Chiriqui).
- klagesi*. **C. klagesi** *Rothsch.* (14 g) is somewhat larger than the preceding from which it otherwise differs by the white forehead and breast and a white middle spot on the thorax; at the base of the wings two white, small spots; the distal margin is black in a more uniform width, the black discoidal spot is absent. Trinidad.
- braconoides*. **C. braconoides** *Wkr.* (14 g). Except the last 3 segments the abdomen is peculiarly diaphanous brownish-yellow, which makes the insect appear repulsive; all the rest is blackish-brown, just like a series of dorsal spots varying greatly in extent on the abdomen. On the head and base of the forewing 2 white dots each. Discoidal spot very large. Widely distributed in Mexico, also in Honduras.
- stibosticta*. **C. stibosticta** *Btlr.* (14 g) differs from *braconoides* by the absence of the discoidal spot and an entirely unmarked abdomen. Panama, Colombia, Ecuador, Bolivia. — The white spots on the head, thorax, hips and bases of the wings may be absent altogether: **dealbata** *form. nov.* (= ab. 1 *Hmps.*); but instead there may occur metallic blue spots both at the places of the white spots and on the black abdominal apex: **caerulescens** *form. nov.* (= ab. 2 *Hmps.*).
- watsoni*. **C. watsoni** *Rothsch.* (14 g) differs from the similar species by its quite sooty black head and thorax and above all by the uncommonly large round discoidal spot and the very broad black apical spot and distal margin, the latter of which is proximally very deeply indented between the upper median vein and the middle radial vein, so that the hyaline part on the upper median vein comes very close to the margin. Panama (Chiriqui; Lino).
- thia*. **C. thia** *Druce*. Head and thorax black, collar yellow, metathorax with metallic blue spots. The 1st abdominal ring is black, on each side with yellow spots, the 3 next rings are yellow, the last ones metallic blue. Forewings hyaline, costal and inner margins towards the base yellowish, veins brownish-black, distal margin and apex broadly black; hindwings hyaline, bordered with black. Expanse of wings: 32 mm. Ecuador.

C. pseudothia Zerny (= thia Schaus). Head, thorax and legs dark brown; on the forehead and collar some metallic blue scales; hips bluish-black. Abdomen of a bright yellow, the 2 last rings black. Wings hyaline with black veins, margins, apical and inner-angular spots as well as an angled discal spot. Expanse of wings: 29 mm. Costa Rica. *pseudothia*.

C. angustimargo Schaus. Different from *stibosticta* (14 g) by the forehead being only laterally white; on the abdomen only the 2 last segments are black; the white spots on the thorax are absent. Legs dark brown, forehips white-striped. Forewing with a narrow black distal margin. Expanse of wings: ♂ 29, ♀ 37 mm. Costa Rica. *angustimargo*.

C. flavothorax Roths. (14 g). Head metallic blue; collar and shoulder-covers sooty brown, the latter at the base with metallic blue spots; thorax and abdomen golden yellow, the 4 last abdominal rings black with dorsal and lateral metallic blue spots. Legs brown. Margins of the wings brown. — Patria unknown. *flavothorax*.

C. flavothoracides Zerny (= intensa Roths.) (14 h), according to ROTHSCILD's opinion, is probably to be considered as a subspecies of the preceding from which it differs by its orange colouring of the body and a deeper, sooty black of the margins of the wings. Colombia and Ecuador. *flavothoracides*.

C. flavita Schaus. Head black, collar and thorax yellow, the latter anteriorly black-spotted; shoulder-covers distally bordered with a brownish black. Legs black, forehips yellow; abdomen yellow, the 2 last rings black. Wings hyaline with black bases, veins, margins and apical spots; costa of the forewing towards the base hyaline. Expanse of wings: 38 mm. Colombia. *flavita*.

C. ockendeni Roths. (14 h). Head, thorax and abdomen, except the three first orange segments, black. The orange segments exhibit black lateral stripes. Breast yellow, legs and antennae black. Subcostal space like the wings hyaline. A small black apical spot. Described from Peru. *ockendeni*.

C. plagiata Roths. (14 h). Head and thorax black; abdomen yellow, the last segment and a large dorsal spot on the rings 3 to 5 black; breast yellow, legs and antennae black. Subcostal space of the forewings hyaline; discoidal and apical spots black. Peru. *plagiata*.

C. pytna Druce. Head and thorax black, the former with lateral blue spots; neck and collar yellow, bordered with black; abdomen yellow, 2nd and 3rd rings black, with lateral spots of a brilliant metallic blue; the last rings black, with blue spots. Wings hyaline with yellow bases; veins, margins and apical spot broadly black; inner margin of the forewing orange. Expanse of wings: 40 mm. Trinidad. *pytna*.

C. xanthomelan Zerny (= rosenbergi Roths. pr. p., pulchrum Roths.) (14 h). Head and thorax black, with metallic blue spots; immediately distinguishable from the similar species by the orange-yellow metathorax with a blue middle spot. The abdomen is orange, the two last rings black with metallic blue spots. Legs orange with blackish-brown tarsi. The basal costal-marginal half and the proximal margin of both wings orange. Ecuador. *xanthomelan*.

C. buchwaldi Roths. (14 h). Body sooty blackish-brown, vertex white; the sides of the first 3 abdominal rings are orange-yellow. Antennae and legs blackish-brown, forehips and tibiae yellow. The margins of the wings, a discoidal and a large apical spot black, at the base of the proximal margin on each side of vein 1 an orange-yellow stripe. Ecuador. *buchwaldi*.

C. harpalyce Schaus. Blackish-brown; neck with white dots; spots on the shoulder-covers and lateral stripes on the 3 first abdominal rings orange, as well as lateral hair-tufts at the base of the abdomen. The middle rings are beneath orange. Wings hyaline with brown veins and margins; at the base of the forewing there are 2 white dots. Inner-marginal angle of the forewing brown. Expanse of wings: 44 mm. Brazil (Rio de Janeiro). *harpalyce*.

C. regia Schaus (= nicippe Druce) (14 h) is well recognizable by the broad black base of the forewing with 2 large hyaline spots in it; the discoidal spot is connected with the inner angle by black embedment between the median veins. The first abdominal rings are above and laterally carmine-pink, the rest of the abdomen black with white spots which are of a magnificent sky-blue opalescence on the first segments. Colombia, Venezuela, Peru. *regia*.

C. bogotense Fldr. (14 h) resembles the preceding, though it is smaller and easily discernible by a great reduction of the hyaline spots; the dorsal and subdorsal abdominal spots are of a bright metallic blue. Described from Colombia (Bogotá), in the Coll. SEITZ also from San Carlos (Costa Rica), thus apparently widespread. *bogotense*.

C. intensum Wkr. (14 m) is smaller than *regia*, all the spots being white there are here brilliantly metallic blue, only the forehips and the under surface of the 4 last rings are white. On the first abdominal ring paired carmine spots; the 3 last rings exhibit lateral orange spots. The wings are yellowish hyaline with black veins, margins, apical spots and base. Hindwing at the inner margin whitish. Expanse of wings: 30 mm. Honduras. *intensum*.

ladan. **C. ladan** Druce (= *intensa* Druce) (14 i). Near to the preceding. Body blackish-brown; collar and base of shoulder-covers with carmine spots; vertex and thorax sparsely scaled in blue. Forehips and venter white; the abdomen exhibits above 2 violettish-red, small spots, lateral blue spots; the posterior margins of the segments are above more or less bordered with blue. Wings hyaline with black veins, margins, apical and proximal angle, as well as discal spots; on the hindwings the discal spots and distal margin are somewhat scaled in a metallic blue. Expanse of wings: 30 mm. Panama (Chiriqui).

30. Genus: **Poecilosoma** Hbn.

Like *Cosmosoma*, but on the forewings the uppermost radial vein rises from below the upper cell-angle. Lower half of the cell of the hindwing very small, lower radial and lower median vein on a long footstalk.

chrysis. **P. chrysis** Hbn. (= *megaspila* Wkr.) (14 i) looks almost exactly like *Cosmosoma ignidorsia* (13 b), but it is sufficiently marked by the low rising of the uppermost radial vein. Besides the distal half of the shoulder-covers is black, spotted blue, and the red lateral spots on the 2nd abdominal ring are absent. Described from the Amazon, before me also from French Guiana.

nigerrimum. **P. nigerrimum** Wkr. (14 i) exhibits a quite black body with metallic blue spots. The comb-like teeth on the antennae are reddish-yellow. Wings yellowish hyaline with orange-yellow veins. Amazon (Ega).

eusebia. **P. eusebia** Druce (14 i) has the head and thorax spotted orange-yellow and black; the orange-yellow abdomen shows on the first segment some small black spots; on the 2nd and 3rd rings there are black, subdorsally blue-spotted transverse bands, the 4th and 5th rings show black, blue-pupilled subdorsal spots, the last rings are black. The faintly yellowish hyaline wings are orange at the costal and proximal margin. Forehips spotted blue. Ecuador.

eone. **P. eone** Hbn. (14 i). Head and thorax are black with silvery bluish-green spots; the forehead and stripes on the shoulder-covers are white. The first abdominal ring is carmine with yellowish spots, the two next rings exhibit lateral red spots, the rest of the abdomen is black with white dorsal and lateral spots being margined by metallic greenish-blue. The base of the proximal margin on the forewing is extensively greenish-blue silvery. From the Amazon, Pará, São Paulo, Santa Catharina.

mapirens. **P. mapirens** Strand. It reminds us of *Cosmosoma xanthistis* Hmps., but it has more pointed wings with a narrower marginal band; the base of the proximal margin of the hindwing is only little orange; base of abdomen black, rest of abdomen black with 4 longitudinal rows of bluish-green spots. Collar and shoulder-covers orange, the latter bordered with black. Head, breast and hips blue-spotted. Expanse of wings: 28 mm. Based upon a rubbed-off ♂ from Bolivia.

misionum. **P. misionum** Strand greatly resembles the preceding, but the 4 anterior abdominal segments are beneath and laterally orange, partly also the hindlegs; subcostal space hyaline. The transverse-vein spot of the forewing is broader; the base of the hindwing is more extensively orange-yellow. Antennae at the ends white. Whether the abdomen exhibits also green spots, cannot be stated by reason of the defective preservation. Expanse of wings: 29 mm. Argentina (Misiones).

marginatum. **P. marginatum** Wkr. (14 i). Body black, forehead, vertex, and thorax with metallic blue spots. Base of palpi, collar, shoulder-covers, breast and stripes on the legs orange-red. The abdomen exhibits a dorsal row of metallic blue spots and broad, orange-red lateral stripes. Subcostal space of the forewing orange-red. From the Amazon District.

vespoides. **P. vespoides** Schaus (14 i) has an entirely orange-yellow body. Black are: the distal side of the terminal joint on the palpi, dorsal and lateral spots beginning from the third abdominal ring, stripes on the outside of the legs, and the antennae. Base of forewing and subcostal space from the transverse vein as far as the apex orange. Margins of wings very narrowly black; a very minute apical spot. Described from Peru; before me also in some specimens from Colombia (Ibaque, 2700 m).

31. Genus: **Mystrocneme** H.-Schäff.

Like the preceding, but the lower half of the cell on the hindwing is of a normal size, and the lower radial vein and the lower median vein, therefore, are much shorter pedicellate; the first median vein rising in the preceding genus close before the margin, is absent here; the spurs are very short.

varipes. **M. varipes** Wkr. (= *geminata* H.-Schäff.) (14 k) is distinguished by peculiar, rough scent-scales on the under surface of the wings in the ♂, being situate on the lower cell-angle and at the apex of the forewing and the distal half of the hindwing; besides, the posterior tibiae of the ♂ in the distal half exhibit an enlargement

with a depression in it. The body is black; forehead, shoulders and hips white-spotted; collar and legs blue-spotted, the first abdominal ring exhibits a large white dorsal spot, as well as lateral white spots, the rest broad, golden green subdorsal stripes. Venter white. Wings extensively black with hyaline spots. Amazon (Pará); known also from Venezuela and French Guiana.

M. atavia *Hmps.* (14 k) differs from *varipes* by more extensive hyaline spots on the wings, the absence of the dorsal white basal spot on the abdomen, instead of which there are 2 smaller subdorsal spots, and besides by the absence of the ventral valve and of the rough scaling on the under surface of the wings, as well as by the absence of the enlargement of the posterior tibiae in the ♂. Amazon (Fonteboa).

M. flavicinctata *Dogn.* Black; forehead white, collar and shoulder-covers with metallic green spots; a spot on the shoulder and the 3 first abdominal rings above and at the sides yellow, the other black rings exhibit metallic green lateral stripes. Venter white with black segmental margins. Hips white. Wings black, with the same hyaline spots as in *varipes*, but behind the cell there are 4 instead of 3. Expanse of wings: 28 mm. British Guiana. *flavicinctata.*

M. sectum *Kaye.* Black; the forehead and spots on the shoulders and at the sides of the venter of the 1st abdominal ring are white. Collar, shoulder-covers and mesothorax with metallic green spots. The abdomen exhibits green lateral stripes. The wings are quite black, only the forewings show a small hyaline stripe below the cell. Expanse of wings: 28 mm. British Guiana. *sectum.*

M. albicarpus *Kaye.* Black with a white-spotted forehead, shoulders and hips. Legs outside with metallic green spots. First abdominal ring white, the 2nd bordered with white, both laterally pale metallic green; the other black rings are likewise laterally green. The venter shows a broad, white middle stripe and short, whitish lateral stripes on the 2 first rings. Wings hyaline with large, black discal and middle spots. Expanse of wings: 28 mm. British Guiana in June. *albicarpus.*

M. rubricarpus *Kaye.* Black; forehead white, collar green, base of shoulders with carmine spots, shoulder-covers with metallic green stripes. The 2 first abdominal rings are scarlet, the 3rd to 5th are laterally red, the others quite black, laterally scaled metallic green. Wings hyaline with a broad black apex and a large, square, black inner-angular spot; costa narrowly, proximal margin broadly black. Hindwings broadly bordered with black, the cell being filled up with black. Expanse of wings: 28 mm. British Guiana in April. *rubricarpus.*

32. Genus: **Dixophlebia** *Btlr.*

Only 2 small, sombre-coloured species distinguished by dense, fur-like hair on the radial and median veins and the lower subcostal vein of the forewing above. Both median veins rise in common near the lower cell-end from which the two lower radial veins rise.

D. quadristrigata *Wkr.* (14 k) is a blackish-grey insect with an orange thorax, thinly scaled wings with oblong hyaline spots in and below the discocellulars. From the Amazon, Minas Geraes, Santos, Sa. Catharina. *quadristrigata.*

D. holophaea *Hmps.* (14 k). Unicolorously blackish-grey, otherwise like the preceding species. Guiana. *holophaea.*

33. Genus: **Phoenicostacta** *Hmps.*

Very closely allied to the following, chiefly differing by the posterior tarsi being above fringed with long scales, the upper radial rising from below the upper cell-angle.

Ph. haematabasis *Hmps.* (14 k) has a blackish-brown body with red spots on the shoulders; the first abdominal ring exhibits 2 almost contiguous, subdorsal red spots, being otherwise laterally blue-spotted. The hyaline spots on the wings are confined by broad blackish-brown margins, and on the forewing by the middle spot being connected with the proximal margin. South Brazil (Sa. Catharina, Rio Grande do Sul). *haematabasis.*

34. Genus: **Ichoria** *Btlr.*

This genus comprises a small group of species distinguished by mostly entirely scaled forewings in which the uppermost subcostal vein rises from the cell; the hindwings are mostly in the middle hyaline diaphanous and exhibit a strongly angular discocellular, the lower median vein and the lower radial stand on a long footstalk. The straightly porrect palpi extend beyond the forehead. The smooth abdomen shows in the ♂ on the ventral side a large valve covering the basal segments.

- multigutta*. **I. multigutta** Schaus (14 k). Body black. Collar, shoulders, the dorsum of the first abdominal ring and the base of the forewing with deep carmine spots; the other segments exhibit red subdorsal lines, the three first ones besides sublateral spots. Forehips and a broad band across the ventral valve white. Wings hyaline with a black discoidal and apical spot. Venezuela (Aroa).
- bricenoi*. **I. bricenoi** Rothschild. (14 k) differs from the very similar preceding species by its larger size, greatly reduced red colour, the ventral valve being in its anterior half brown, and the antennae being strongly thickened and not serrate. Venezuela (Merida).
- tricincta*. **I. tricincta** H.-Schäff. (14 k) resembles the following, but it is larger and differs by its carmine neck and collar, the latter with a black middle spot, as well as carmine lateral spots on the 1st abdominal ring. Anus with some red hairs. Expanse of wings: 42 mm. Colombia; Brazil (Rio de Janeiro, São Paulo).
- demonia*. **I. demonia** Druce. Forewing unicolorously black, the hindwing likewise black except a hyaline spot being situated below the cell and in the spaces behind the cell. Head black with metallic blue scales on the forehead. Palpal base orange-yellow; antennae black, before the tips white for about 3 mm in extent. Collar and thorax orange-yellow. Collar on each side with a metallic bluish-green spot. Forehips and base of femora red, legs otherwise black. Abdomen black, the first ring exhibits a small, orange dorsal spot, the 2 or 3 following rings subdorsal ones, on the dorsum and at the sides with metallic blue spots. Known only from Mexico (Jalapa). —
- orizabena*. f. **orizabena** form. nov. (14 l). From Orizaba (August) there is a form before me, which would perhaps be better regarded as a distinct species. It differs by the following marks: the distal, larger half of the collar black, with metallic blue spots; the metathorax exhibits a large, black spot with a metallic blue pupil, on the prothorax a silvery green, not carmine opalescent spot. The abdomen exhibits instead of one dorsal, two smaller subdorsal orange spots, the following 3 subdorsal ones are absent. The whole under surface, the 4 last abdominal rings also above, entirely metallic bluish-green. Type in the Coll. DRAUDT. — f. **atra** form. nov. I denominate another form from Mexico, in which the orange colouring of the thorax has disappeared altogether, only the two orange subdorsal abdominal spots being yet visible.
- improcera*. **I. improcera** spec. nov. (14 l) greatly resembles the forma *atra* described above. The body is entirely black without any orange colouring. The palpi are quite black; the black antennae are white at the extreme tips (in the *demonia*-forms quoted above the tips themselves are black, while the white colour is only in front of them). Only the forehips are red, the legs otherwise quite black. Forehead, collar, meso- and metathorax, as well as the abdomen dorsally with metallic blue spots, broad metallic bluish-green lateral stripes. The wings like in the preceding, but the forewings at the base with metallic bluish-green spots. The inner-marginal area of the hindwing more broadly hyaline. Panama (Chiriqui). (BANG-HAAS).
- maura*. **I. maura** spec. nov. (14 l) is another species likewise greatly resembling the preceding, but immediately distinguishable by quite blackish-brown hindwings without any hyaline spots. The blackish-brown body is spotted metallic blue on the forehead and vertex, collar and metathorax; palpi, antennae and legs are black, forehips carmine. Shoulder-covers with orange stripes. Abdomen with dorsal and lateral rows of bluish-green spots. The blackish-brown forewings at the base with metallic blue spots. Described according to a male example in the Coll. SEITZ, from Venezuela.
- quadrigutta*. **I. quadrigutta** Wkr. (14 l) is easily discernible from the similar species by white, not red forehips. On the shoulders and the first abdominal ring there are carmine spots. Body with metallic green spots. Wings like in the preceding, but the hindwings in the basal half hyaline. Expanse of wings: 34 mm. Mexico; Guatemala; Costa Rica.
- semiopaca*. **I. semiopaca** Dogn. is coloured on the body like the preceding, but much smaller, and on the forewings there are hyaline spots between the veins, in and below the cell; those between the first median vein and the middle radial vein extend farther towards the margin than the others. Hindwings hyaline with a broad black border and costal margin. Expanse of wings: 28 mm. Brazil (São Paulo).
- chrostosomides*. **I. chrostosomides** Schaus has a black body; a spot on the shoulder and a stripe on the shoulder-covers are red. Forehips and tibiae white-striped. Wings smoky brown hyaline with black veins, a broad black proximal margin and narrow apical spot. Hindwings covered with black scales except the proximal margin. Expanse of wings: 20 mm. French Guiana.
- chalcomedusa*. **I. chalcomedusa** Druce (14 l). Blackish-brown with a metallic green abdomen being subdorsally black-striped. Forehead, collar, shoulders, meso- and metathorax with metallic blue spots; tips of antennae white. The veins of the brown forewings are slightly greenish-striped. Hindwings hyaline with a black margin. From Brazil (Amazon, Sa. Catharina, Paraná).

35. Genus: **Pseudomya** Hübn.

Distinguished from the closely allied genus *Saurita* by the very long hindlegs, the tibiae and tarsi of which are covered with scales. On the forewings the two lower radial veins do not quite rise from one place, but a little separately.

P. splendens Druce (141) has a black body with orange-yellow spots on the collar, breast, hindhips, *splendens*. laterally on the first abdominal ring, sublaterally on the second and subdorsally on the third and the next segments. The antennae are orange; the wings greenish-black, with orange spots. Bahama Islands.

P. minima Grote (14 m). The more bluish-black ground-colour and the white, not yellow spots distinguish *minima*. this species sufficiently from the preceding. From Florida and Cuba. — The orange-red larva being dorsally and sublaterally dark striped with hair-brushes on the dorsum lives in December on *Myginda ilicifolia* and changes to a light brown lustrous pupa in an elliptic web.

P. sithon Druce (14 m). Blackish-brown; ends of antennae and forehips white; spots at the base of *sithon*. the shoulder-covers and lateral abdominal stripes are carmine; wings hyaline with very broad blackish-brown margins. — In f. **flavescens** n. n. (= ab. 1. *Hmps.*) the red parts are orange-yellow. Mexico; Guatemala. *flavescens*.

P. ochreiventris Dogn. The body is greyish-brown; spots at the sides of the forehead, at the base *ochreiven-* of the shoulder-covers, as well as 2 transverse bands above the 2 first abdominal rings, anal hairing, first palpal *tris*. joint, hips and the first abdominal rings beneath are ochreous. At the sides of the abdomen there are metallic blue spots. Wings thinly scaled greyish-brown; more densely scaled at the cell-end of the forewing. Expanse of forewings: 26 mm. Ecuador.

P. picta Schaus (141) has a greyish-brown body; forehead bordered with whitish. Vertex, shoulders, *picta*. and metathorax exhibit carmine spots. The two first abdominal segments and broad lateral stripes on the others are yellowish-white. Wings hyaline greyish-brown. From Venezuela and Guiana.

P. sanguiceps *Hmps.* (14 m). Body black, on the head and shoulders red spots, on the metathorax *sanguiceps*. two red spots. Wings blackish diaphanous, the forewing exhibits a large, faded blackish discoidal spot, the hindwing being black in the whole distal half. From Panama.

P. melanthus Cr. (= *trigutta* Wkr.) (14 m) is larger than the preceding. Colour of the body more *melanthus*. reddish-brown, the vertex is black, forehips and the last abdominal rings beneath white. Wings brownish diaphanous with brown veins and margins. Colombia; Surinam; Brazil.

P. nigrozona Schaus. A very small species with a blackish-blue body. Forehips and venter except *nigrozona*. the last segments whitish. Wings smoky brownish hyaline, the forewing with a broad black median band being continued on the apical half of the hindwing; proximal margin of the forewing black. Expanse of wings: 19 mm. French Guiana.

P. naenia Druce (15 a) is unicolorously blackish-brown, only at the base of the shoulder-covers there *naenia*. are small red spots; ends of antennae white. Wings blackish-brown, the hindwing exhibits small hyaline spots in and below the cell. Expanse of wings: 24 mm. Guatemala.

P. translucida Dogn. (15 a) has a quite unicolorously black body. The wings are hyaline with sparse, *translucida*. blackish-brown hairs, veins and margins being black. The forewings exhibit a faded, blackish median shade being intensified to a black spot at the lower cell-end. Expanse of wings: 24 mm. Ecuador (Loja).

P. trabea Druce. Body black, hindhead, sides of thorax, and base of abdomen red; the 1st abdominal *trabea*. ring yellowish-white. Both wings smoky hyaline, at the apex and distal margins more darkened. Expanse of wings: 26 mm. From British Guiana to Ecuador.

P. absona spec. nov. (15 a) resembles exteriorly much rather a small *Cosmosoma*. The body is uni- *absona*. colorously brownish-black, only 2 longitudinal streaks on the mesothorax and the ventral side of the 3 first abdominal rings are light ochreous. The wings are hyaline, with black bases, narrow margins, middle spot of the forewing and apical spots. One male example from Peru (Marcapata, BANG-HAAS).

36. Genus: **Holophaea** *Hmps.*

A small group of mostly dull coloured, delicate insects with rather broad forewings with a long, oblique distal margin, usually entirely scaled, but still half diaphanous. On the hindwings the lower median vein and lower radial vein rise from the lower cell-angle, the upper median veins rises from the lower mostly very near the margin, but this varies and the 3 veins may also rise in common from the cell-angle; the cell itself is large, the discocellular angularly bent. The palpi are straightly porrect and extend beyond the head. Antennae serrate or doubly dentate like combs.

H. vesta Möschl. (15 a). In this small species the head and the last abdominal segments are black, *vesta*. thorax and the 4 first abdominal rings orange coloured; shoulder-covers at the tips black. The hyaline wings exhibit very broad, blackish-brown margins. Guiana, Brazil.

- gentilicia*. **H. gentilicia** *Schaus.* Forehead dark brown with metallic blue scales; vertex, collar and thorax red. Antennae and abdomen black, the last segments with a blue lustre. Under surface and legs brown. Wings dark brown, at the base of the costa and in the submedian area with red spots; hindwing below the cell blackish. Expanse of wings: 30 mm. Costa Rica.
- lycone*. **H. lycone** *Druce* (15 b). Body blackish-brown with a slight purple-blue lustre. On the shoulder-covers and the dorsum of the first abdominal segment carmine spots. Forewings semi-diaphanous blackish-brown, veins darker. Hindwings light grey diaphanous. Mexico (Orizaba, Misantla, May and August), Costa Rica, Panama.
- endoleuca*. **H. endoleuca** *Dogn.* (15 b) greatly resembles the preceding, though it is considerably larger, the wings being of a deeper and purer dull black colour, and with a much more extensive red transverse band on the first abdominal segment. The body is much more abundantly spotted metallic green, of the same colour are the hips. At the base of the costa on the forewing there is yet a red spot. From *Saurita diffusa* being coloured exactly the same it merely differs by its narrower wings and the pendent palpi. Colombia.
- melita*. **H. melita** *Druce* likewise resembles the two preceding species, being as large as *endoleuca*. Body and wings unicolorously blackish-brown, the sides and last rings of the abdomen of a brilliant metallic bluish-green, underneath brownish white; only a small spot on the metathorax is carmine. Ecuador.
- lugens*. **H. lugens** *Jones* is quite unicolorously blackish-brown. Posterior tarsi for the greatest part and in the ♂ the forehips white. Expanse of wings: ♂ 28 mm, ♀ 32 mm. Brazil (São Paulo).
- prometina*. **H. prometina** *Druce* (15 b). Brownish-black; a line behind the eyes, stripes on the shoulder-covers and abdominal sides orange-yellow. Wings semi-diaphanous blackish-brown with an orange stripe at the base of the costa. Mexico (Vera Cruz).
- caerulea*. **H. caerulea** *Druce* (15 b) is unicolorously deep ultramarine blue. Collar and borders of the shoulder-covers carmine. Ecuador.
- ruatana*. **H. ruatana** *Druce* (15 b). Blackish-brown; base of palpi, vertex and hindhead, collar and shoulder-covers orange. Hips whitish. The wings are unicolorously blackish-brown. Expanse of wings: 20 mm. Honduras.

37. Genus: **Hypatia** *Kirby*.

Rather near to the preceding genus, from which it differs by erect palpi, the middle radial vein rising from above the lower cell-angle, whereas the upper one rises from below the upper cell-angle. On the hindwing the first median vein is present and rises close in front of the margin.

- delecta*. **H. delecta** *Btlr.* (= *astyche Wkr.*) (15 b). Head, collar and abdomen bluish-black, thorax orange. Forehead, dots on the shoulders, forehips, dorsal and lateral stripes on the abdomen and a broad middle stripe on the venter are white. Wings hyaline with fine black veins and a narrow costal margin. Proximal margin and apical spot broadly black, the latter reaching the cell above the middle radial. Hindwings black, in the cell-end a white spot. Expanse of wings: 26 mm. Pará.
- melaleuca*. **H. melaleuca** *Wkr.* (16 b) resembles the preceding, but all the orange colouring is absent, but instead there are white dots on the collar and thorax. Pará.

38. Genus: **Psilopleura** *Hmps.*

Some medium-sized species with quite dark or hyaline-spotted, long, narrow wings. The first median vein of the forewing rises near the cell-angle, both the lower radial veins from the cell-angle, the upper one from below the upper cell-corner. On the hindwing the lower median and lower radial veins rise from the lower cell-angle or on quite a short footstalk; the first median vein and the middle radial are absent. The antennae of the ♂ are provided with rather long comb-like teeth.

- sanguinea*. **P. sanguinea** *Jones*. Head blackish-brown; collar brown, bordered with silvery white; thorax brown, anteriorly intermixed with carmine and single white scales. Shoulder-covers inside and anteriorly broadly bordered with carmine. Hips and abdomen carmine. The first ring brown, laterally with a red and white spot, the other rings show a brown median stripe being lighter in the middle; the rings 4 to 6 exhibit silvery white subdorsal spots. Wings yellowish, diaphanous, suffused by blackish; base black, behind it a yellow subcostal stripe; at the cell-end there is a large yellow spot extending from the costa as far as the rise of the median veins, outside and inside shaded with black. Hindwings from the costa to the median fold black, from there as far as the inner angle hyaline with a black border. Expanse of wings: ♂ 20 mm, ♀ 22 mm. Brazil (Castro, Paraná).

P. vittata *Wkr.* (15 b). A species greatly varying in size, colouring and extent of the hyaline spots. *vittata*. Mostly dark coffee-brown. The neck, a stripe on the mesothorax and two broad lateral stripes on the abdomen are orange-yellow. Antennae black, before the apex white. The brown forewings exhibit a darkening in the apical part of the costal margin as well as along the inner margin; at the border there are in the spaces between blackish-brown sagittate streaks. In the cell 2 cuneiform hyaline spots, a long one below them extending with 2 teeth between the 2nd median vein and middle radial towards the margin; 2 small hyaline spots below and above the upper radial. Hindwings diaphanous with a broad black border, the inner margin at the base orange. Nearly all the year round common in Mexico (Orizaba, Misantla, Vera Cruz, Yucatan) and Guatemala.

P. polia *Druce* (15 c) approximates the preceding species, but it is much larger and differs by its *polia*. lighter colour, much more extensive hyaline spots, almost entirely hyaline hindwings and on the under surface a whitish inner-marginal part and costal base. Brazil (Espiritu Santo). — f. **minax** *form. nov.* (15 c) of which *minax*. about 20 specimens of both sexes from Mexico are in my collection, I am inclined to include with *polia* as a subspecies, as I know *polia* only from the figure and description; it is, however, not impossible that it is a distinct species. It stands between *vittata* and *polia*, but it is twice as large as the former from which it is also easily discernible by its more light grey ground-colour; the darkening at the apex and inner margin is absent, instead of which there are here long black streaks in the cell-spaces between the yellowish prominent veins. Hindwings with narrower and duller grey margins; the whole proximal margin extensively orange yellow, also the base of the inner margin of the forewing. The abdomen is much more extensively orange and exhibits only a narrow dorsal stripe, being in the middle light grey, at the edges dark brown. From *polia* it differs by the bright orange-yellow, not whitish colour at the costal and proximal margins of the hindwings beneath, as well as by the much more confined hyaline spots of the forewings and a considerably broader border of the hindwing. Widely distributed in Mexico: from Tehuacan (Puebla), Misantla, Orizaba, Mexico, Zacualpan, San Luis Potosi, flying from May to October together with *vittata*, the genital organs of which are different.

P. klagesi *Rothsch.* (15 b). Palpi and forehead are black, the vertex reddish-yellow; thorax dark *klagesi*. brown with a reddish-yellow longitudinal band. Abdomen deep orange, a broad middle stripe and the last segment dark brown. Legs blackish-brown, with white rings, hips yellowish-white. Antennae brown with a white apical third. Forewings dark-brown with minute white spots in and below the cell as well as behind the cell. Hindwings white with a broad blackish-brown marginal band. Venezuela (Bolívar; Caracas).

P. pentheri *Zerny* greatly approximates the preceding species and chiefly deviates by the quite uni- *pentheri*. colorously coffee-coloured forewings growing a little lighter towards the margin and exhibiting a series of inconspicuous light marginal dots, as well as by brownish-black hindwings the base of which is narrowly yellowish, with a narrow white longitudinal spot below the cell and a larger roundish spot behind the cell. The ventral side of the abdomen is coffee-coloured with a yellowish-white longitudinal stripe as far as the 4th segment. Brazil (Bahia).

P. dolens *Schaus* (15 c). Body dirty brownish black, on the shoulders and shoulder-covers one red *dolens*. spot each. The wings are brownish diaphanous with brownish-grey margins. Described from Costa Rica, one example from Bahia in the Coll. SEITZ.

P. sanguipuncta *Hmps.* (15 c) differs from the preceding by its larger size and the more dark-brown *sanguipuncta*. wings from which brownish hyaline spots are contrasting in the cell as well as below and behind it, so that a broad, faded, brown median band and a broad apical spot become prominent. The veins are still darker brown. Brazil (Rio Grande do Sul).

P. albipes *spec. nov.* (15 c) is a beautiful species belonging near the two last ones. Body jet-black; *albipes*. shoulders and a square spot on the first abdominal segment are deep carmine. The thorax and the ventral sides of the first 4 abdominal rings is white like the upper surface of the posterior tarsi. Wings blackish diaphanous with black margins and apical spot. The type is a ♂ from Santos in the Coll. SEITZ.

P. hymenopteridia *Rothsch.* (15 c) is a most peculiar, little species which looks exactly like a Hymenop- *hymenopteridia*. teron flying with it and is entirely unlike the genus. Palpi, head, antennae and thorax are black, the tapering abdomen is chestnut-red, the two last segments black, forelegs yellow, hips white; middle legs brown, tibiae and tarsi yellow; hindlegs brown, tibiae yellow, banded. Wings diaphanous dirty yellowish, distal third with brownish clouds. Bolivia. This species, known to me only from description, presumably belongs to the following genus and seems to be allied to *pimpla*.

39. Genus: **Rhynchopyga** *Fldr.*

Peculiar, very slender, small species with narrow, usually brown and orange wings, the neuration of which hardly differs essentially from that of the allied genera: on the hindwings the lower median and lower radial veins are long petioled.

- pimpla*. **R. pimpla** *spec. nov.* (15 c) connects the following species with *Psil. hymenopteridia*. From the following species it differs by the entirely red collar and thorax. The 2 last abdominal rings are only above black. Wings more intensely yellow hyaline; behind the median spot of the forewing the costa is yellow for some distance. From South Peru (Madre de Dios). Type in the Coll. FASSL.
- ichneumonea*. **R. ichneumonea** *Fldr.* (15 c). Body blackish-brown, neck and edges of the collar white; the 2nd to 5th abdominal rings are carmine. Wings semi-diaphanous, blackish-brownish with lighter hyaline stripes in and below the cell, and a darker median spot. Expanse of wings: 36 mm. Colombia.
- semirufa*. **R. semirufa** *Druce*. Head and thorax black, with a bright red neck, collar and abdomen, the latter with a black dorsal line. Chest and legs black; at the base of the abdomen a large white spot. Wings brownish hyaline, the forewing at the base red. Veins, distal margin and apical spot black. Expanse of wings: 25 mm. Peru.
- xanthospila*. **R. xanthospila** *Hmps.* (15 d) differs from the similar species by the carmine lateral stripes extending as far as the end of the abdomen, as well as by the orange-yellow costal-marginal spot being situated yet within the hyaline parts; the subcostal space is hyaline. The anterior body is black, the shoulder-covers and sides of thorax are carmine. Ventral valve white. Bolivia (Rio Songo).
- rubricincta*. **R. rubricincta** *Hmps.* (15 d) has a black body; the shoulder-covers, and partly the second and third abdominal rings are orange-red, the venter whitish. Wings blackish, basal third orange-red, a transverse band behind the cell from the costal margin to the inner angle are orange-yellow. Oblong hyaline spots are in and below the cell and between the 2nd median and 3rd radial. The hindwings are orange at the base and costal margin orange, the apex and proximal margin blackish. Hitherto only from Bolivia.
- xanthozona*. **R. xanthozona** *spec. nov.* (19 h) resembles the preceding in its exterior. The wings are broader, rounder, otherwise coloured and marked the same, but the postdiscal orange band grows much broader towards the inner angle. The species is immediately recognizable by the scarlet collar and sides of the thorax. Thorax and shoulder-covers above dark brown. Abdomen above black, the 2nd and 3rd rings orange-yellow. Venter white; ventral valve black, at the base white-haired. Legs orange-yellow. Posterior tibiae and tarsi black. South Peru (Madre de Dios; FASSL).
- braconida*. **R. braconida** *Kaye*. Head and thorax lustrous green. The 2 first abdominal rings carmine, the others greenish-black; below the eyes and at the shoulder-covers white dots. Legs greenish-black, hindlegs very long, underneath at the joints white. Forewings in the basal half greenish-black, distally black; at the costal margin behind the cell a large orange spot. Hindwings blackish diaphanous. Expanse of wings: 28 mm. Brazil (Santos).
- meisteri*. **R. meisteri** *Berg* (15 d) is blackish-brown; collar and shouldercovers are bordered with deep carmine, with interspersed, bluish-whitish scales; the lateral tubercles at the 1st abdominal ring are deep carmine; the lateral spots and the underside of the 4 first segments likewise deep carmine, with interspersed bluish-silvery scales, particularly at the margins. The dark brown forewings exhibit in the proximal half narrow hyaline stripes not extending as far as the base, and at the base an ochreous-yellow spot becoming indistinct in the ♀, and a similar spot behind the middle of the costal margin; hindwings hyaline with a broad, blackish-brown margin. Brazil, Paraguay, Uruguay and Argentina in October to December and March to April on compositae.
- castra*. **R. castra** *Jones* (15 d) is closely allied to the preceding, and immediately discernible from it by the absence of the yellow basal spot, the smaller size and the hyaline stripes extending as far as the base of the forewing. Brazil (Paraná; Rio Grande do Sul).
- subflamma*. **R. subflamma** *Druce* (15 d). Black, collar bordered with white, abdomen orange, with dorsal and lateral black spots, at the end black. Forewings blackish-brown with a narrow hyaline stripe in the basal half in and below the cell. Hindwings hyaline with a black border. Expanse of wings: 28 mm. Panama.
- semiflava*. **R. semiflava** *spec. nov.* (15 d). Head and thorax are blackish-brown; forehead; collar and shoulder-covers proximally bordered with bluish-silvery scales; the distal half of the shoulder-covers is ochreous-yellow. The abdomen is above blackish-brown, except the two last light ochreous-yellow segments; the ventral side and large lateral spots at the base of the abdomen are ochreous-yellow. Legs blackish-brown, hips with whitish scales. The forewings are thinly yellowish scaled, towards the base of a deeper orange, with a broad blackish-brown distal and proximal margin, hindwings semi-diaphanous yellowish with a blackish-brown distal margin. Described according to a female example from Colombia (Rio Aguaca Valley, 2000 m); type in the Coll. FASSL.
- flavicollis*. **R. flavicollis** *Druce* (15 c) is easily recognizable by the orange neck and collar, whereas the body and wings are blackish-brown, the latter with hyaline stripes in the proximal half; the hindwings are quite hyaline with narrow brown margins and veins. Guatemala; also from Panama (Lino).

R. metaphaea *Hmps.* (= *flavicollis* *Druce*) (15 e) deviates from the preceding by its quite unicolorously *metaphaea*. blackish-brown fore- and hindwings. Mexico (Guerrero); Honduras.

R. steniptera *Hmps.* is quite monotonously blackish-brown with very narrow and long wings, the *steniptera*. hindwings being somewhat lighter. Expanse of wings: 24 mm. British Guiana.

R. albigutta *spec. nov.* (15 e) is unicolorously blackish-brown on its body and wings. The palpi, *albigutta*. except the black terminal joint, throat and neck are orange-yellow. The forewings, being comparatively broad, exhibit behind the cell a white spot between the upper median vein and the 4th subcostal vein. The hindwings are in the disc diaphanous with broad brown veins. One ♀ from Peru (Cuzco, BANG-HAAS).

40. Genus: **Cercocladia** *gen. nov.*

In the exterior it greatly resembles the *Rhynchopyga*-species from which the sole species is immediately discernible by the strong middle radial vein of the hindwing rising above the lower middle of the cell. The lower radial vein stands on a long footstalk with the upper median vein, the lower median vein rises behind the cell-middle. All the rest like in *Rhynchopyga*. The genera are hardly allied to each other, and there are many resemblances to *Hypocladia* and *Cercopimorpha*.

C. novicia *spec. nov.* (15 d) is a magnificent, most complicatedly coloured species. The body, except *novicia*. the 3 last blackish-brown abdominal rings, is of a deep vermilion; forehead blackish-brown with a metallic blue middle spot; palpi orange-yellow with a black terminal joint; antennae blackish-brown; collar and the shoulder-covers being outside blackish-brown are bordered with bluish-silvery; across the thorax and abdomen extends a bluish-silvery median line; with the same colour the segmental indentations are bordered, and on the third and fourth segments there are large lateral spots. The brown abdominal apex exhibits an orange-yellow lateral line and underside. Hips, middle and hind legs red; foreleg orange, anterior tibiae blackish-brown, outside with a red median band, the rest blackish-brown. The forewings are dark brown; at the end of the basal third there is a very oblique hyaline band extending from the subcosta to the submedian fold; the costa above it is orange-yellow; at the extremity between the middle and distal third of the costal margin there is an orange-yellow spot. The median vein and the base of its branches are steel-green. The blackish-brown hindwings exhibit a hyaline median band, the distal bordering of which on the cell-fold strongly bends in towards the base and which reaches the base in the direction of the inner margin; the basal half of the costal margin of both wings is beneath orange-yellow. — Described according to 2 fresh ♂♂ from Cuyaba (Matto Grosso), obtained by BANG-HAAS.

41. Genus: **Hypocharis** *Hmps.*

The only species with rather broad wings greatly approximates the following genus, but on the forewings the upper radial vein rises below the upper cell-angle; the two lower ones stand on a very short, joint footstalk. On the hindwings the median veins rise on a joint footstalk, the lowest radial with the same from the lower cell-angle.

H. clusia *Druce* (15 e). Blackish-brown; shoulders, shoulder-covers and dorsum of the first abdominal *clusia*. ring with carmine spots. On the collar, metathorax and at the sides of the abdomen there are metallic blue dots. Forewings yellowish-white with blackish-brown veins, in the larger basal half smoky olive-brownish, with a large blackish-brown apical spot. The very broad hindwings are semi-diaphanous blackish. The species has been described from the Amazon, but I also possess it from French Guiana.

42. Genus: **Saurita** *H. Schöff.*

The genus contains a number of species looking exteriorly very unlike each other; the one group comprises little, delicate, gnat-like insects with semi-diaphanous wings of a slender structure; the other larger group has species being mostly provided with densely scaled wings, with a thick, disproportionate abdomen; others again remind us of the genus *Macrocneme*. Common to all are the erect palpi, doubly (in the ♂ very long-)combed antennae. The cell of the hindwing is long; the lower median and lower radial vein rise from its lower angle, or they are shortly petioled; the upper median vein, in case it be present, from the upper angle of the cell, close in front of the border.

S. cardinalis *Rothsch.* (15 e). This little species does not resemble any other: head, antennae and *cardinalis*. abdomen are bluish-black, like the distal two thirds of the wings; the basal third of the wings and the vertex and thorax are carmine. The legs are blackish-brown. Costa Rica.

- mecrida*. **S. mecrida** Druce (= *dulcicordis* Dyar) (15 e). The delicate, long-extended wings are blackish diaphanous, abdomen and mesothorax of a magnificent scarlet, the collar is bordered with bluish-white. The ♂ exhibits more, less developed, black spots on the dorsum and the sides of the abdomen. It flies in October and November in Mexico (Mexico City and Durango).
- ochracea*. **S. ochracea** Fldr. (= *musca* Schaus, *pontia* Druce) (15 e). The tiny, gnat-like insect is blackish except the ochreous-yellow abdomen, with semi-diaphanous, long, narrow wings. Flying in March to September in Mexico (Orizaba, Misantla, Coatepec) and in Colombia.
- improvisa*. **S. improvisa** Schaus. Easily distinguishable from the preceding by its orange-yellow thorax being anteriorly spotted black and white. Shoulder-covers black; the abdomen on the first segment subdorsally spotted black. The wings are more brownish hyaline, in the distal third thinly scaled. Veins and fringes blackish-brown. Expanse of wings: 24 mm. Costa Rica.
- bicolor*. **S. bicolor** Dogn. differs from *ochracea* (15 d) by its blackish-brown forewings exhibiting narrow hyaline stripes only in and below the cell, and by the hyaline hindwings with brown veins and margins. Besides, the abdomen being yellow in the ♂ shows a black dorsal line and, beginning from the 4th ring, also lateral stripes. In the ♀ the abdomen is carmine instead of yellow. Argentina (Tucuman).
- tricolor*. **S. tricolor** Schaus has an orange body, only the head with the antennae and the 4 last abdominal rings are black. Femora and tarsi yellow, tibiae black, forewings black, in the median area ochreous yellow, hindwings ochreous-yellow with a broad black margin. Expanse of wings: 23 mm. French Guiana.
- hamon*. **S. hamon** Druce. Body bluish-black, collar red-brown. Legs dark brown. Forewings lustrous reddish-brown. Hindwings hyaline, margins black, with an intense blue lustre. Expanse of wings: 35 mm. Peru.
- cryptoleuca*. **S. cryptoleuca** Wkr. (15 f) is, with the following, the sole species with light metallic bluish-green hindwings and thereby very easily recognizable. The body and the forewings are black; vertex, collar, legs, base and sides of abdomen are spotted metallic bluish-green. On the shoulders and at the sides of the 1st abdominal ring carmine spots. The forewings exhibit stripes of metallic bluish-green scales in, behind and below the cell. The hindwings are diaphanous below the cell and at the proximal margin, the veins and margin being black. Forehips and ventral side white. Described from the Amazon; in my collection also from Guiana, and from Venezuela.
- watsoni*. **S. watsoni** Rothsch. (15 f) is easily distinguishable from the preceding by the hyaline spots on the forewings being peculiarly distributed. Panama (Chiriqui).
- biradiata*. **S. biradiata** Fldr. (15 f). Body black; hips, stripes at the front femora and ventral side white. Forewings black, below the base of the cell thinly scaled, in the cell-end 2 bluish-green stripes; behind the cell, between the 2nd median and 4th subcostal vein there are hyaline spots. Hindwings hyaline with black veins, margins, apical and inner-angular spots. Expanse of wings: 28 mm. Amazon.
- tristissima*. **S. tristissima** Perty (15 f) shows on its velvety black body small metallic green spots, and at the side of the 1st abdominal ring as well as at the base of the forewing small red spots. The wings are hyaline with black margins and veins. Amazon (Pará, Massauary).
- attenuata*. **S. attenuata** Hmps. (= *tenuis* Btlr.) (15 b). Body black. Shoulder-covers and base of the wings spotted red; hips and femora with white stripes. Wings hyaline with black veins, proximal margin and apical spot. Expanse of wings: 22 mm. Amazon.
- diffusa*. **S. diffusa** Schaus (15 f). The ♂ is distinguished by quite uncommonly broad forewings and particularly hindwings, in the ♀ they are narrower. Body and wings are sooty black. Bright metallic green spots are on the forehead, sides of the vertex, collar, metathorax and at the sides of the abdomen. Spots on the shoulders and a large square spot on the base of the abdomen are carmine. Forehips metallic green. Costa Rica.
- latens*. **S. latens** Schaus has a black body with red spots on the shoulders and dorsally on the 1st abdominal ring. Anterior tibiae inside yellow-reddish. Wings blackish-brown with darker veins. Expanse of wings: ♂ 25 mm, ♀ 30 mm. Costa Rica.
- submacula*. **S. submacula** Schaus is dark brown on the body and wings; the shoulders exhibit a large carmine spot; on the forehead, collar and mesothorax, as well as at the costal base single blue scales. On the hindwings below the base of the cell there is a reddish stripe and a small pink spot. Expanse of wings: 36 mm. Costa Rica.
- hemiphaea*. **S. hemiphaea** Dogn. Body black with some small, metallic green scales; outside at the collar a white dot, shoulders with red spots. Legs black, hips white. Wings hyaline, iridescent violet, veins and margins black, the proximal halves of the wings strewn with blackish. Expanse of wings: 23 mm. French Guiana.

S. rubripuncta *Schaus.* Body black; forehead, vertex, collar, shoulder-covers, thorax and abdomen *rubripuncta* laterally with metallic blue spots. At the base of the abdomen above a red transverse streak; beneath with a metallic green lustre, behind it a large white spot, hips white. Wings hyaline, at the base of the forewing a carmine spot; veins, margins and apical spot black, as well as a broad median band terminating into the inner angle. Expanse of wings: 29 mm. Costa Rica.

S. mediorubra *Kaye.* Head, thorax and abdomen black, base of shoulder-covers and dorsum of the *mediorubra*. 1st abdominal ring with large carmine spots. Wings semi-diaphanous blackish, with black veins, margins, apical and inner-marginal spots; legs and ventral side black. Expanse of wings: 34 mm. South Brazil (Santos).

S. anthracina *Klages* is one of the largest species with a black body, the forehead, vertex, collar, *anthracina*. shoulders, chest and thorax spotted metallic blue with single white scales between them. Legs blackish-brown. Abdomen with dorsal and lateral stripes of metallic green, and with sublateral spots. Wings blackish-brown with a blue lustre. Expanse of wings: 42 mm. Venezuela.

S. cassandra *L.* (15 f) is very much like *nigripalpia*, of a more brown ground-colour with darker *cassandra*. veins and a faded discoidal spot, also between the median veins there is darker colouring. The base of the palpi and borders of the collar are red. Widely distributed from Venezuela to Argentina, also in Trinidad.

S. erythroguia *Hmps.* (15 f) looks like a very large *nigripalpia*; the abdomen exhibits at the base *erythroguia*. only one red spot, the forehips are red. Before me only from Brazil (São Paulo).

S. nigripalpia *Hmps.* (= *cassandra* *Druce*) (15 g). Clumsy, unicolorously black species with densely *nigripalpia*. scaled wings. Vertex, shoulders and collar with metallic blue spots. Sides of thorax, middle and posterior hips, the first abdominal ring above and at the sides, and the base of the shoulder-covers exhibit scarlet spots. The abdomen shows lateral metallic bluish-green spots, and the apex of the abdomen is scarlet. The quite black palpi separate the species from the similar, though more brownish *cassandra*. Common in the whole of Mexico (from May to August). In Costa Rica there flies a form more similar to *cassandra*: — **costaricae** *costaricae*. *Strand* (= subsp. 1 *Hmps.*) in which the wings turn brownish between the veins, the metallic blue spots being absent on the head and thorax.

S. vitristriga *Druce* (15 g). Black; collar with metallic blue spots; abdomen with metallic green dorsal *vitristriga*. and lateral stripes, with sublateral white spots as well as on the chest and hips. In the ♂ the ventral valve is blackish-brown with broad white borders, the four last rings on the ventral side ochreous yellow. The black wings show hyaline spots of extremely varying extent. Venezuela; British and French Guiana.

S. sanguisecta *Hmps.* (15 g) has a black body; the collar, shoulders, mesothorax and forehips with *sanguisecta*. carmine spots; the abdomen shows carmine articular indentations and silvery blue spots between. The hyaline forewings, at the base with a carmine spot, exhibit a large discoidal spot, being connected with the costal margin and inner angle, as well as a large apical spot; also on the hindwing there is a discoidal spot connected with the anal angle, in the shape of a large, blackish-brown, triangular spot. Colombia.

S. mora *Druce* (15 g). Black, suffused with blue, with white spots on the forehead, vertex, collar, thorax, *mora*. hips and joints. Chest anteriorly with carmine spots. Abdomen above and laterally with white spots, venter white. The black forewings, at the base with a white and blue spot, exhibit hyaline spots below the base of the cell in the middle and end of the cell, above the lower median vein, and a dot above the upper median vein. Hindwings in the cell with a white stripe. Expanse of wings: 30 mm. Panama.

S. lacteata *Btlr.* (15 g). Body brown, on the shoulders and shoulder-covers with carmine spots. *lacteata*. The abdomen exhibits on the dorsum and the first rings laterally whitish-yellow colour. The brown forewings are yellowish-white below and behind the cell, with brown veins, the hindwings yellow-white with brown veins and margins. Expanse of wings: 24 mm. Amazon; found also in Trinidad.

S. nox *Druce* (15 g) resembles the preceding, but on the abdomen the yellow-white colour is absent *nox*. altogether, instead of which there is a red dorsal spot on the first ring. The red spots of the shoulders are absent, the shoulder-covers exhibit red stripes. Forewings thinly covered with brownish-black scales, with darker veins, and a postdiscal, faded, whitish spot. Hindwings diaphanous greyish-black. Expanse of wings: 22 mm. Honduras; Venezuela.

S. perspicua *Schauss.* Body black, with red spots on the shoulders and shoulder-covers. Forehips *perspicua*. grey. Forewings smoky brownish hyaline with black veins and fringes and a more dense black dusting at the base and proximal margin. Hindwings more whitish, dusted with black below the cell and at the distal margin. Expanse of wings: 27 mm. Trinidad.

S. phoenicosticta *Hmps.* (= *trigutta* *Druce*) (15 g). Black with red spots in the neck, at the base *phoenicosticta*. of the shoulder-covers and on the metathorax. Posterior tarsi at the ends white. Wings blackish, diaphanous. From Guatemala and Costa Rica.

- clandestina*. **S. clandestina** Zerny (= *cryptoleuca* Hmps.). Black; vertex and collar with small blue spots; shoulders and metathorax with red spots. Abdomen on the first and last segments above, on the two penultimate ones laterally with blue spots. Wings black with hyaline stripes in and below the cell and quite small ones behind the cell. On the under surface dusted with white. Expanse of wings: 32 mm. Organ Mountains.
- incerta*. **S. incerta** Wkr. (= *corallonota* Fldr., *intermedia* Druce) (15 h). Dull black; forehead laterally white. Vertex and thorax orange-red; forehips white. The black forewings being spotted orange at the base exhibit narrow hyaline stripes in and below the cell. Expanse of wings: 24 mm. Panama; Colombia.
- salta*. **S. salta** Schaus (15 h) is distinguished from the numerous similar species by an orange-red hindhead, white forehead and forehips; from *incerta* particularly by the absence of the red spot at the base of the forewing. Venezuela.
- venezuelensis*. **S. venezuelensis** Klages (15 h) is black, the collar, shoulder-covers and thorax above orange, beneath black. On the head, the body and base of forewings some silvery blue scales. In the ♂ only the basal halves of the wings are hyaline, the marginal halves black, thinly scaled, whereas the ♀ has entirely hyaline wings with darker veins and margins. The species is smaller than *temenus* and distinguished by the thorax being only above orange, being, however, also above black in f. **obscura** Klages. The species is not rare in Venezuela and French Guiana.
- tijuca*. **S. tijuca** Schaus. Head black; thorax orange; abdomen above black, beneath whitish. Forewings diaphanous blackish. Hindwings hyaline, towards the margin darker. Expanse of wings: 30 mm. Brazil.
- thoracica*. **S. thoracica** Klages is dark blackish-brown; forehead whitish; thorax and chest orange-red. Forehips and stripes at the anterior tibiae white in the ♂. The blackish-brown wings are orange-red at the base. Expanse of wings: ♂ 20 mm, ♀ 25 mm. Venezuela.
- sanguinea*. **S. sanguinea** Druce (15 h). Discernible from the following by the 1st abdominal ring being entirely orange-red, the forehead being only laterally white striped, and by the absence of the hyaline spots behind the cell of the hindwing; in place of it there is usually a small orange spot behind the lower cell-angle. Guatemala.
- myrrha*. **S. myrrha** Druce (15 h) is recognizable from among the great number of similar species by the subdorsal orange-red spots on the 1st abdominal ring, by the extensively orange-red base of the wings and hyaline spots on the hindwings in, below and behind the cell. Forehead white. Guatemala.
- vindonissa*. **S. vindonissa** Druce (15 h). The head, the white-dotted collar, and the shoulder-covers are black; the other part of the thorax, the 2 first abdominal rings, and lateral spots on the third ring are orange-red; the other segments are black, all the rings subdorsally, the first dorsally with white spots. The ventral side orange-red, legs black. The black forewings exhibit hyaline spots in the basal half; the hindwings are hyaline with a black border and discoidal spot. Ecuador.
- tenuis*. **S. tenuis** Btlr. (15 i) has a brick-red thorax; the other part of the body is black with metallic blue spots on the head, collar, base of the abdomen and laterally on the last-abdominal rings. The wings are black, in the middle hyaline. Brazil (Espírito Santo).
- astyoeche*. **S. astyoeche** Hbn. (15 h) differs from the preceding by its smaller size, quite black, not blue-spotted head and collar, more orange-red thorax, and by the hindwings being without any hyaline spots behind the cell. Expanse of wings: 30 mm. Surinam; Brazil (Rio Grande do Sul).
- temenus*. **S. temenus** Cr. (= *afflicta* Wkr.) (16 b) differs from the following by distinct hyaline spots in the cell-spaces. The upper median vein is present on the hindwings, whilst in the following species it is absent. Trinidad; Surinam; Pará; Maranhão.
- concisa*. **S. concisa** Wkr. (= *afflicta* Druce) (15 i) has the thorax orange-red above and beneath; the rest of the body and the wings are black; the latter between the veins somewhat more thinly scaled. On the hindwings 2 and 4 are short-petioled, 3 is absent. Panama to the Amazon.
- intricata*. **S. intricata** Wkr. (= *catastibina* Btlr.) (15 i) resembles on the whole *tenuis* Btlr., though it has a quite black thorax. Brazil (Rio de Janeiro, Espírito Santo). — ab. **augusta** Btlr. is a female form resembling the ♂, in which the hyaline spots are absent behind the cell.
- sericea*. **S. sericea** H.-Schäff. (= *demoanassa* Druce) (15 i) looks entirely like a *Macrocneme*: black with white dots on the forehead and the first abdominal ring; the abdomen shows metallic green longitudinal stripes. The black forewings being at the base metallic bluish-green exhibit a small, oblong, hyaline spot at the base of the costal margin. Occurring from Panama to Argentina.
- triangulifera*. **S. triangulifera** Druce (15 i) likewise resembles in its colours a *Macrocneme*: black, suffused with bluish-green, tarsi and spots at the base of the abdomen white. The black wings being metallic bluish-green in the basal halves exhibit whitish hyaline spots in the basal part of the costal margin, below the base of the cell, and quite a narrow one at the cell-end. Brazil (Amazon, São Paulo).

S. bipuncta *Hmps.* (15 k). Very much like the preceding, but the white spots are absent on the first *bipuncta*. abdominal ring, and the hyaline spot in the cell-end is absent, too; the species is besides larger. Distributed from the Amazon to Argentina.

S. melanifera *Kaye* from Santos, South Brazil, is a quite unicolorously sooty black, small animal. *melanifera*. Expanse of wings: 27 mm.

S. tipulina *Hbn.* (= *bibia Wkr.*) (15 k). Beside single interspersed, small scales of metallic green *tipulina*. on the head and prothorax, it is unicolorously sooty black. The abdomen exhibits a grey dorsal stripe being often indistinct; wings semi-diaphanous with black veins. On the hindwings the lower median and radial veins rise unpetioled, the upper median vein is present. Widely distributed from Mexico (Misantla in May) through Guatemala and Panama as far as Brazil (Pará, Sao Paulo, Espiritu Santo, Sa. Catharina).

S. trichopteraeformis *Jörgensen*. I cannot tell whether this species, having remained unknown to *trichopteraeformis* me, may be identical with *melanifera*. The body is short and rather squat. Of a pure black, the wings at a certain exposure to the light with a greenish lustre. Veins somewhat more densely scaled. Posterior hips with white stripes. Expanse of wings: 30 mm. Argentina (Bonpland) in November.

S. lasiphlebia *Dogn.* (15 k) is smaller and of a more compact structure than *tipulina*, abdomen and *lasiphlebia*. wings shorter and broader, the wings are lighter transparent, of a very intense green and carmine iridescence, the colour is a plain, dull blackish-brown, the metallic green scales are absent, the veins of the wings are covered with very thick, velvety brown scales; the grey dorsal stripe on the abdomen is absent. French Guiana.

S. diaphana *Dogn.* Body quite unicolorously black. Wings long and narrow, blackish hyaline, of *diaphana*. a rather intense iridescence. Veins and fringes black; costa and base of the forewing and proximal margin of the hindwing more densely scaled black. Expanse of wings: 26 mm. South East Peru (Carabaya).

S. pellucida *Schaus* (15 k) has a velvety-black body and in the ♀ semi-diaphanous blackish forewings; *pellucida*. the hindwings and in the ♂ the apical third of the forewing lighter transparent. Brazil (Rio de Janeiro; Santos).

43. Genus: **Sauritinia** *Dyar.*

The only species deviates from *Saurita* by the presence of an accessory cell on the forewing, only the 3 lower subcostal veins rising from a joint footstalk, whilst the 2nd subcostal vein rises from the cell itself before its upper corner, in order to form together with the said footstalk a long, accessory cell.

S. dubiosa *Schaus* is very similarly coloured to *Saurita sanguinea* (15 h), but considerably smaller. *dubiosa*. The body is black, collar, thorax and 1st abdominal ring orange-red. The wings are diaphanous smoky brownish with darker veins; on the forewing the costal and proximal margins, as well as a streak on the cell-fold are black. Expanse of wings: 21 mm. French Guiana.

44. Genus: **Scena** *Wkr.*

Only 2 species somewhat similar to each other, of a considerable size and with densely scaled wings. Thorax and abdomen are densely covered with woolly hair, the palpi erect. On the hindwings the upper median vein and the middle radial vein are absent. On the forewings both the upper subcostal veins rise separately from the cell, only the lower ones are petioled.

S. potentia *Druce* (15 l). The smaller one of the two species; blackish-brown with a slight, greyish-blue *potentia*. lustre. Collar, mesothorax, and the shoulder-covers being at the apex bordered with black, are orange. Antennae white at the tips. Mexico (Jalapa; Orizaba) and Costa Rica.

S. styx *Wkr.* (= *propylea Druce*) (15 k). One of the largest *Syntomidae*. Head, collar, mesothorax and *styx*. the shoulder-covers being black at the apex are dark orange, on each side of the collar a peculiarly opalescent, amethystine spot. Antennae black with a white apex. Ends of the posterior tarsi likewise white. Wings and abdomen black. The wings exhibit at the bases and at the cell-ends lustrous ultramarineblue spots. Abdomen above, at the sides and beneath likewise with blue spots. Apparently only from Mexico (Mexico-City, September, Jalapa). — The larva lives gregariously on a creeper with red blossoms.

45. Genus: **Micragyrta** Btlr.

Proboscis well developed; the slender palpi are erect and extend with their 2nd joints beyond the vertex, the 3rd joint being very small. Tibiae with short spurs. The veins of the forewings differ from those of the allied genera by the two uppermost subcostal veins rising from the cell on a joint footstalk, whereas the three lower ones are separately petioled. On the hindwings both the median veins stand on a long footstalk; the lower radial vein comes from the lower cell-angle. The subcostal vein and the uppermost radial vein are likewise petioled.

diminuta. **M. diminuta** Wkr. (= *gavisa* Wkr.) (15 l). The only species known hitherto most strikingly copies small *Agyrta*-species and also *Mimagyrta pampa* (12 k). The body is black with a blue lustre extending to the basal halves of the wings. The wings exhibit hyaline spots arranged exactly like in *pampa*. Forehead white. Expanse of wings: 30—34 mm. Amazon (Pará).

46. Genus: **Metaloba** Hmps.

In their exterior, the two species remind us of the genus *Calonotos* from which they differ by the short-petioled 2 uppermost subcostal veins of the forewing, by the much shorter cell of the hindwing, as well as by the petioled subcostal vein and 1st radial vein. In the ♂ the costal vein is rudimentary; the proximal margin exhibits an oval, lobular appendage containing in a fold thick woolly hair.

nana. **M. nana** Druce (15 l). Black; palpal base, forehead and collar, and at the sides of the first abdominal ring with white dots. The abdomen exhibits yellow-golden, dorsal and lateral longitudinal stripes. On the black forewings there are below the middle of the cell one, behind the cell 3 hyaline spots in both sexes. The appendage of the hindwing is black with brown hair. Colombia.

argante. **M. argante** Druce (15 m) differs from *nana* by metallic green longitudinal stripes on the abdomen. The forewings exhibit only one round hyaline spot behind the cell in the ♀, whereas the ♂ exhibits three, like *nana* in both sexes. The appendage in the ♂ is whitish with ochreous yellow hair. Expanse of wings: 42 mm. Ecuador.

47. Genus: **Psoloptera** Btlr.

Differing from the preceding genus by the unpetioled subcostal vein and uppermost radial vein on the hindwing, and by the absence of appendage of the proximal margin. The rudimentary costal vein is absent, too. On the forewing the first median vein distinctly rises below the lower cell-angle; the two lower radial veins run for some distance near each other, the upper radial vein comes from below the upper cell-angle. The subcostal veins rise on 2 petioles, as in the preceding.

basifulva. **P. basifulva** Schaus (= *thoracica* Druce) (15 m) differs from the following species by its larger size, somewhat narrower wings and the more orange-red colour of the thorax, which also extends to the base of the wings. From Panama, also from Peru.

thoracica. **P. thoracica** Wkr. (15 m) has wings of a deep indigoblue lustre, a dark carmine thorax, and white dots on the vertex, shoulders and first abdominal ring. Guatemala, Panama, Ecuador, East Colombia, Amazon, Peru.

leucosticta. **P. leucosticta** Hbn. (15 m) differs from the preceding by the black colour of the thorax; the first abdominal ring exhibits two white dorsal spots. Venezuela, Guiana, Amazon, Trinidad.

aurifera. **P. aurifera** H.-Schäff. (15 l, m) is considerably larger than the preceding. Blackish-brown, tips of the antennae white. Collar, shoulder-covers, mesothorax and first abdominal ring with green spots, the other rings show dorsal and lateral golden-green stripes. The blackish-brown forewings are in the basal halves golden-green and exhibit in the ♀ small white spots below the middle of the cell and behind the upper cell-angle, or only on either of them. Expanse of wings: 50 mm. Amazon (São Paulo).

48. Genus: **Eurota** Wkr.

This genus contains a number of rather variegated species the exterior of which reminds us of the Indo-Australian *Euchromia*. The squat abdomen exhibits on the segments lateral short hair. The antennae are thickened in the middle part of the shaft. The neuration does not exhibit any characteristic marks.

E. hermione *Burm.* (16 a). Among the species with yellow and red lateral stripes on the abdomen *hermione*. and a red proximal part of the hindwing, it has the largest hyaline spots and is considerably larger than the following. On the blackish-brown body there are yellow spots on the collar, shoulders and forehips; the anal margin of the 1st segment exhibits 2 yellowish-white spots. On the 5th and 6th rings the yellow and red lateral spots form transverse bands across the dorsum. The ventral side is yellowish-white on the first segments. Argentina. — The larva strikingly resembles that of *strigiventris* and mostly lives gregariously on *Senecio albi-caulis* and *pinnatus*.

E. paraguayensis *Schrottky* (26 k) which was considered by the author to be a form of *hermione*, is, *paraguayensis*. according to JÖRGENSEN, a distinct species; it is considerably smaller, of a much lighter brownish ground-colour; only the first abdominal ring exhibits laterally some red; the white dots at the posterior margin of the same ring are much smaller; the segments 4 and 5 exhibit laterally 2 distinctly defined, yellow spots. It flies in Argentina and Paraguay from January to June on compositae, in clearings as well as in the woods.

E. tisamena *Dogn.* greatly approximates the preceding, but all the yellow spots are here white. The *tisamena*. 4 first abdominal rings show above 2 white dots each, fading away posteriorly; the 5th and 6th rings exhibit white transverse bands with a lateral carmine tint; at the sides a series of white dots with single, small red scales. Venter, except the 2 last brown rings, entirely white. Wings as in *hermione*. Expanse of wings: 33 mm. Brazil (São Paulo: Paranapanema).

E. minerva *Schaus* approximates the preceding. Body black; collar and anterior half of the shoulder-covers exhibit large yellow spots. The 3 first abdominal rings show lateral carmine spots, the 2 next ones yellow spots. Forewings black, at the base a yellow stripe; base of proximal margin with red hair. The wings exhibit hyaline spots arranged the same as in the preceding species; but below the spot, being situated under the median, there is another, small, fourth spot, and the postmedian row of spots consists only of 4 spots. Hindwings as in *hermione*. Expanse of wings: 27 mm. Castro (Paraná). The species also greatly resembles the following, though it is much smaller, the hyaline spots larger.

E. schausi *Hmps.* (= *helena Schaus*) (16 a) differs from the preceding by the much smaller spots on *schausi*. the wings, its much larger size and the entire absence of the white dots at the posterior margin of the 1st abdominal segment. Brazil (Paraná).

E. igniventris *Burm.* (16 a) is greatly distinguished by the body being quite red; mesothorax and *igniventris*. outside of the shoulder-covers black. The abdomen shows black, blue-pupilled, dorsal spots on the 1st, 3rd and 4th segments. On the vertex, collar and thorax there are single scales of a blue lustre. The black wings exhibit yellow transverse bands. Argentina; before me there is a ♀ from BANG-HAAS without the patria being stated.

E. semiluna *Wkr.* (16 a). Black; palpi, vertex, collar and proximal margin of the shoulder-covers, *semiluna*. as well as the posterior margin of the thorax carmine. The 1st abdominal ring shows red spots, the 2nd a carmine band, and the 3 last ones red, confluent dorsal spots increasing in size posteriorly; the middle rings are bordered with metallic blue. Wings black, with orange spots, arranged in the same way as in *igniventris*, but a little more confined by the black ground-colour. Expanse of wings: 48 mm. Brazil.

E. selva *H.-Schäff.* (16 a). Blackish-brown; collar orange and scarlet; red are, furthermore, the meta- *selva*. thorax, lateral bands on the 3 first abdominal rings and spots on the 2 last segments, the 4th and 5th show above orange and red transverse bands, being strangulated in the middle. The forewings show hyaline stripes at the costal base, in and below the cell, as well as an irregular hyaline band behind the cell between the 2nd median and the 4th subcostal vein. Hindwings entirely hyaline with black veins and an irregular marginal band. Expanse of wings: 34 mm. Argentina.

E. herrichi *Btlr.* (= *sericaria H.-Schäff.*) (16 a) has the abdomen yellow curled except the last black *herrichi*. segment, and a carmine metathorax; the spots on the forewings are not quite constant and are inclined to coalesce. The basal spot on the hindwing is tinted red at the base. Paraguay; Rio Grande do Sul; Argentina.

E. sericaria *Perty.* Blackish-brown with yellowish-white collar and shoulders; metathorax carmine. *sericaria*. The 4 first abdominal rings have white bands, the others are quite blackish-brown. Wings similarly marked as in the preceding, but with a long white subcostal stripe extending as far as two thirds of the costal margin. Expanse of wings: 42 mm. Brazil (Rio de Janeiro; Minas Geraes).

E. vulcanus *Wkr.* (16 b) is a very large, differently coloured species. Black; tips of antennae, spots *vulcanus*. on the shoulders, sides of thorax, subdorsal and sublateral, oblong transverse spots on the abdomen white. Anterior femora and the lateral tufts on the abdomen are carmine. Wings black with hyaline spots arranged similarly as in *stictibasis*, but the base is not yellow, and on the hindwings, below the base of the cell there is another large hyaline spot. Expanse of wings: 52 to 60 mm. Mexico.

E. histrio *Guér.* (16 b) is blackish-brown with large hyaline spots of an orange-yellowish lustre on *histrio*. the wings. Forehead, metathorax, dorsum and sides of the abdomen exhibit white spots; collar and shoulders

with metallic blue spots; stripes on the shoulder-covers and lateral large spots on the 3 first abdominal segments are carmine. A common species occurring from Bolivia to Paraguay.

baeri. **E. baeri** *Rothsch.* (16 c). One of the smallest species with a black body; palpi, spots on the shoulders as well as broad lateral stripes on the abdomen are carmine. The hips and sublateral spots on the abdomen are white. The antennae are black, before the tips with a white band. The black wings are spotted white. Argentina (Tucuman, 600 m).

parishi. **E. parishi** *Rothsch.* (16 c) is one of the smallest species and greatly resembles the small Indo-Australian *Syntomis*-species. The body is black; forehead, shoulders and forehips are white; the first 5 abdominal rings are reddish white with black dorsal spots on the second to fourth segments; the other rings are black, the abdominal apex reddish white. The black wings exhibit diaphanous white spots. Cuba.

stictibasis. **E. stictibasis** *Hmps.* (16 b) is blackish-brown with hyaline spots on the wings, the one at the base of the forewing is more or less yellow. The collar and 2 rings on the two penultimate abdominal segments are yellow. The sides of the 3 first abdominal rings exhibit triangular, bright red spots, those of the first segment being connected on the dorsum by a yellow transverse streak. From Brazil (Sao Paulo).

maritana. **E. maritana** *Schaus* (16 c) differs from the preceding by the collar being only narrowly margined with yellow, and the entirely black ventral valve of the ♂. It has a long basal spot below the median, the hindwings exhibit a much smaller spot. Brazil (Paraná).

patagiata. **E. patagiata** *Burm.* (16 c) is easily recognizable by the bright red base of the forewing, and the whole inner-marginal half of the hindwing is red, too. On the blackish-brown body the collar and transverse bands on the 1st, 4th and 5th abdominal rings are white or yellow; the abdomen has lateral red spots, the 4th and 5th rings on the ventral side white bands. Argentina.

picta. **E. picta** *H.-Schäff.* (= *pictula* *Wkr.*) (16 c) is likewise similar to *stictibasis*, but all the abdominal segments are broadly margined with a bright yellow, the base of the proximal margin of the hindwing is yellow and carmine. Occurring from Venezuela to Paraguay, where it is found in open districts on compositae nearly all the year round. — The larva is light yellow with short, greyish-black, paired dorsal brushes and with white, black-haired, small tubercles; the head is brown. It often lives gregariously in different compositae and spins a soft, yellowish, somewhat transparent cocoon with interwoven hairs.

elegans. **E. elegans** *Druce* is considerably larger than the preceding and deviates by an entirely black collar; of the same colour are the head, antennae, palpi, legs and apex of abdomen. The abdomen is otherwise unicolorously pale yellow, the first ring and the sides of the 2nd and 3rd rings bright red. Forewings black, at the base light yellow. Spots, and the red base of the proximal margin of the hindwing like in *picta*. Expanse of wings: 50 mm. Paraguay.

strigiventris. **E. strigiventris** *Guér.* resembles the following, being somewhat smaller and distinguished by large, golden-yellow spots on the shoulders, as well as by the abdomen, exhibiting only lateral rows of large, triangular, golden-yellow spots being connected with each other. Venter with 2 rows of white, more or less triangular spots flowing posteriorly together. Wings very much like in *helena*, the basal spot of the forewing consists of 3 white spots. South Brazil to Argentina. — subsp. **boliviana** *nom. nov.* (= subsp. 1. *Hmps.*) is considerably smaller, particularly the ♀ has much smaller wings; the middle spots on the wings are smaller. Bolivia.

helena. **E. helena** *H.-Schäff.* (16 c) (= *laetifica* *Maass.*) is distinguished from all the other species by the abdomen being curled light yellow as far as the end, the red colour being altogether absent; the venter shows 2 rows of sublateral white spots. The brown wings exhibit white spots, at the base of the hindwing an orange-yellow spot. The ♀ has much smaller wings with reduced spots. Bolivia, South Brazil, Argentina.

nigricincta. **E. nigricincta** *Hmps.* (16 d) resembles *strigiventris*. Head and thorax blackish-brown; collar laterally yellow; on the metathorax a yellowish-white transverse streak. Abdomen orange, on the 1st ring a black middle spot, on the others black transverse bands, the last segment black; at the sides there is a series of black spots. Venter yellowish-white, with black bands. Wings like in the similar species; the yellow basal spot of the forewing greatly bends inward on the inner-marginal vein; the hyaline spot below the first median is very small and is situate close at the border. The yellow basal spot of the hindwing is small, the hyaline spot extends from the subcostal vein to the lower median vein, the spots above the 1st radial and 2nd median very small. Expanse of wings: 28 mm. Argentina.

spgazzinii. **E. spegazzinii** *Jørgensen* (16 c, 26 m) is very much like *nigricincta* *Hmps.*, but the black dorsal spot on the first abdominal ring is absent, and only the segments 2 to 4 exhibit a narrow black belt; the basal, yellow spot of the forewing runs from the median in a straight line obliquely to the base, and does not bend inward on vein 1. Venter quite orange. The ♀ has stunted wings. It flies in January to April in Argentina. — The yellow larva being provided on the segments 2 to 10 with paired, truncate, blackish-grey hair-tufts and with a red-brown head, lives on *Miacnia scandens* and changes into a light yellow cocoon with interwoven hairs.

E. xanthosoma *Hmps.* is likewise closely allied to the preceding, but it differs by its entirely orange-*xanthosoma*. yellow abdomen, only the last segment being black beneath. Beside the collar and shoulders also the vertex, forehips and chest are orange-yellow. Wings as in *spgazzinii*. Expanse of wings: 30 mm. Argentina.

49. Genus: **Dycladia** *Fldr.*

Half a dozen of small species partly resembling beetles, with the forewings marked yellowish-brown and black, or also with small hyaline spots. A characteristic mark is offered by the antennae being strongly thickened in the middle. On the forewing the first median vein rises with the two lower radial veins from the cell-angle. On the hindwing the lower median vein and the 3rd radial vein rise unpetioled.

D. lydia *Druce*. Black, posteriorly with a blue lustre. Collar, abdominal base and a fine lateral line *lydia*. chrome-yellow. The black forewings exhibit a postdiscal, curved, yellow-hyaline band; on the black hindwings a narrow hyaline stripe runs from the base to the middle of the distal margin. Expanse of wings: 26 mm. South Brazil.

D. melaena *Hmps.* (16 d). Body black; tips of antennae white. Hindhead and collar with orange *melaena*. spots. At the sides of the abdomen there are orange-yellow macular stripes. Wings black with hyaline spots in, below and behind the cell. Bolivia (Rio Songo). — subsp. **brasiliensis** *nom. nov.* (= subsp. 1. *Hmps.*) exhibits *brasiliensis*. hyaline spots only behind the cell between the upper median and lowest subcostal veins, whereas they are absent in and below the cell. Brazil (Sa. Catharina).

D. xanthobasis *Hmps.* The body is blackish-brown, posteriorly with a metallic blue lustre. Base of *xanthobasis*. palpi, hindhead and shoulders with orange stripes. At the sides of the abdomen there are stripes of confluent, triangular, orange-yellow spots. Forewings blackish-brown, at the base orange. Hyaline spots are in and below the cell, as well as an oblique band between the 1st median and lowest subcostal vein, extending as far as the margin and defining proximally a round, blackish-brown discal spot. Hindwings hyaline with black veins, margins, discoidal and apical spots, and an orange-yellow base. Expanse of wings: 26 mm. British Guiana.

D. vitrina *Rothsch.* (16 d). Head and thorax are brownish orange, forehead black, vertex with black *vitrina*. spots, palpal terminal joint black; the thorax shows a black middle stripe; the first abdominal segment is orange with a black middle band, the other rings are metallic blue, black curled. The black antennae are white before the tips. The wings are yellowish hyaline, at the bases, costal margins and veins orange-brown, a large discoidal and apical spot as well as the proximal angle are black. The hyaline hindwings are at the base orange, with a blackish-brown margin. Honduras and Ecuador.

D. lucetius *Cr.* (= *transiens* *Wkr.*) (16 d). Similar to *correbioides*, smaller, the abdomen exhibits as *lucetius*. far as the end broad, orange-brown lateral stripes. In the ♀ the black is more extensive on the forewings, the yellow reduced. Brazil (Pará, São Paulo), Paraguay.

D. correbioides *Fldr.* (16 d). Forewings orange with a black apical spot and black cellular spot which *correbioides*. extends, greatly broadened, as far as the proximal angle, hindwings orange with a black border. Body black, with lateral blue spots on the abdomen. Collar and shoulder-covers orange. The black antennae are white before the tips. Widely distributed and common in Mexico, Guatemala, Honduras, Costa Rica, Panama, Colombia.

50. Genus: **Syntomeida** *Harr.*

Rather large species reminding us of the Indo-Australian *Euchromia*, with dark, white-spotted wings. The erect palpi are at the base provided with long hair. The antennae are thickened after the middle. On the hindwings the lower median and lower radial veins have a short petiole, the upper median vein rises from the lower one shortly before the border, the middle radial is absent.

S. joda *Druce* (16 d). Head and thorax bluish-black, the vertex with metallic blue spots; collar and *joda*. shoulder-covers orange-yellow, bordered with black; forehips with orange and white spots, legs with white stripes. Abdomen black and metallic blue, with subdorsal orange spots on the 1st, 4th and 5th rings. The ventral valve, a spot in the centre of the venter and the anal tuft beneath orange. Wings black, the forewing with a yellowish-white spot in and below the middle of the cell and a second one behind the cell. Also the hindwing exhibits a spot below the cell and one behind it. Mexico.

- hampsoni*. **S. hampsoni** Barnes greatly approximates *joda* (16 d) from which it differs by subdorsal orange-yellow spots on all the abdominal segments. Forehips inside whitish, outside yellow; the anal tuft is only above yellow, at the sides and at the end black. The yellow ventral valve is bordered with black, and the venter exhibits yellow bands. — **befana** Skinner which was based on one example, scarcely differing, may be synonymous. From South Arizona.
- melanthus*. **S. melanthus** Cr. (= *apricans* Wkr.) (16 d). Black with a bronze-green, blue or violettish-blue lustre. Antennae black with white tips; collar and shoulders with orange spots; sides of thorax and hips with white spots. Abdomen with white bands merging into deep orange-yellow and which always remain white on the ventral side. Forewings with pale greenish-yellow spots: a large one below the base of the cell, one in the middle of the cell, and one close beneath it, and 4 in one row behind the cell. Hindwing with a white hyaline spot parted by the veins at the base, and 2 pale-yellow spots behind the cell. The extent and number of the spots varies greatly. Common from Mexico through the whole of Central America as far as Uruguay and Peru. — f. **nycteus** *Stoll* are specimens with greatly reduced spots on the wings. — **nexilis** form. nov. (= ab. 2. *Hmps.*) may be introduced for those specimens in which the two spots below the cell are confluent. — f. **albifasciata** Btlr. (16 e), finally, are the specimens with more or less white abdominal rings, in contrast with the yellow-curved type.
- austera*. **S. austera** Dogn. is much smaller than the preceding; head and thorax quite black with a deep green lustre, of the same colour is the abdomen exhibiting on the two first rings yellowish-white, on the 4 next ones dark brick-red belts; venter with white bands; hips with white spots, as well as the femoral joints of the hindlegs. Tips of antennae white. Forewing with a yellow dot at the base, a larger yellowish-white spot behind it between the median and inner-marginal vein, and a small round spot behind the cell between the upper radial and 5th subcostal vein. Hindwing with several spots, being hyaline at the base, yellowish in the cell. Expanse of wings: 38 mm. Paraguay.
- syntomoides*. **S. syntomoides** Bsd. (= *sauleyi* Guér., *niveifascia* Wkr., *wrighti* Gundl.) (16 e). Black with a blue lustre. The arrangement and number of spots, being here all white and somewhat diaphanous, is similar to that of *melanthus*. The first segment of the bluish-black abdomen exhibits a white band, which may also be broken up into spots or be absent altogether. The three middle segments exhibit on the ventral side white transverse bands. Preponderantly insular inhabitants: Cuba, Bahamas, St. Lucia, Dominica, Barbados, Martinique, but also from Mexico: Cordoba, Misantla, Tehuacan (Puebla) in April and September. — ab. **angasi** Druce has an entirely black ventral side without any white bands. — f. **spiracula** Mén. shows the spots on the wings greatly reduced, the spots in the cell or below the first radial vein are mostly absent altogether; on the hindwing the spot above the 2nd radial is absent. — f. **vidua** Mén. On the forewing also the spot below the middle of the cell is more or less extinct, on the hindwing the inner-marginal spot is absent.
- vulcana*. **S. vulcana** Druce (16 e). Bluish-black; sides of thorax and the hindhips with white spots. The abdomen exhibits on the 1st ring a white dorsal dot and subdorsal spots, and on the 3 middle segments sublateral white spots. The forewing exhibits at the costal base, below the base of the cell and in the middle of the cell yellowish-white dots. The hindwing with a hyaline basal spot. Expanse of wings: 54 mm. Mexico.
- ipomeae*. **S. ipomeae** Harr. (= *ferox* Wkr., *euterpe* H.-Schäff.) (16 e) is bluish-black on the head and thorax; collar, shoulders and thorax above and laterally with orange spots; hips orange; abdomen with broad orange bands. Wings metallic bluish-black, the forewing with an orange-yellow dot at the base, as well as small yellowish-white spots of various development below the base and middle of the cell, behind the upper cell-corner and 2 larger ones behind the lower cell-corner. The hindwings show a hyaline spot below the base of the cell. Expanse of wings: 48 mm. Southern United States.
- epilais*. **S. epilais** Wkr. (16 e). A beautiful, large, bluish-black species with white tips of the antennae. The forewing exhibits at the base of the costal margin a small, snow-white spot, another round one is below the middle of the cell, a small one at the end of the cell and 4 unequally large ones behind the cell. The hindwings exhibit behind the cell-end a white spot. The first abdominal ring exhibits above 2 large white spots with one or 2 dots between, the 3 following rings have lateral white spots. The last 2 abdominal rings are of a deep carmine. Mexico to Honduras. — The red larva with black hairs and hair-pencils on the 3rd, 4th, and 7th to 13th segments, with an orange-red head, according to *Dyar*, lives on *Nerium odoratum* and constructs a thin cocoon interwoven with its hairs, in which it changes into an orange pupa with black stripes and bands. It flies in Mexico from February to July. — v. **jucundissima** *Dyar* (= *epilais* Neum. and *Dyar*) is the form from Florida.

51. Genus: **Enope** Wkr.

Of a much more robust structure than the preceding genus with broader wings. Palpi shorter, more porrect and long haired. The whole body is densely covered with long, shaggy hair. In the neurulation no essential difference. Only one species:

E. toolumnensis *H.-Schöff.* (= *hirsuta* *Wkr.*) (16 e). Body black. Palpi and antennae at the tips white. *tolommen-*
Collar spotted white, legs striped white. Wings with a green lustre and with large yellowish hyaline spots, on *sis.*
the forewing in and below the cell, and an oblique row of 5 spots behind it between the lower median and 5th subcostal vein; at the base there are 2 subcostal, ochreous-yellow stripes. Hindwings subcostally and below the cell with white hyaline stripes, in the cell and behind it yellow hyaline spots. The inner-marginal area black without a green lustre. Expanse of wings: 50 mm. Colombia (Bogotá).

52. Genus: **Xanthomis** *Hmps.*

Characterized by long, roughly haired, porrect palpi, the woolly-haired thorax and abdomen, and the antennae being thickened behind the middle, in the ♀ serrate-dentate. On the hindwings the lower median vein and lower radial vein rise unpetioled from the cell, the first median vein from the lower one shortly before the border.

H. grandis *Druce* (16 f) is an uncommonly characteristic, rather large species, being above bright *grandis.*
orange, beneath black. The border of the wings is narrow at the apex of the forewing and round the proximal angle, on the hindwings broadly black. From Costa Rica; before me there are also specimens from Panama (Chiriqui).

53. Genus: **Hystiaea** *Wkr.*

Very large, robust animals with brown wings being decorated with yellow and red spots and metallic blue dots. On the forewings the upper radial vein rises below the upper cell-angle, just like on the forewings, too; here the discocellular is very large, from its lower corner the lower median and the lower radial vein rise unpetioled. The centre of the range is the Amazon District; only few species reach the southern parts of Central America.

H. paulina *Wkr.* (16 f) is not to be confounded with any other species by the dense hair on the upper *paulina.*
surface of the ♂ hindwings, leaving free only the marginal part. Otherwise like the following from which it differs by the abdomen, which does not exhibit a blue lustre posteriorly and shows only lateral blue spots. The orange-yellow oblique band of the forewings is much broader, the carmine stripes being more distinct and extending farther towards the margin. The hindwings are quite dark brown. Expanse of wings: 70 mm. Brazil (São Paulo).

H. imaon *Hmps.* (16 f) is easily recognizable by the peculiar shape of the hindwings being almost *imaon.*
quite brown, only a very minute red spot is situate at the border above the lower median vein. The forewings exhibit a narrow, orange-yellow band behind the cell and narrow, subcostal and submedian red stripes as well as above vein 1. The brown abdomen is posteriorly quite metallic blue. Amazon (Surimaya).

H. hoffmannsi *Rothsch.* (16 g) is somewhat allied to *imaon* and is at once discernible by the large *hoffmannsi.*
orange-yellow distal-marginal spot on the hindwing, the proximal half of the forewing being almost quite red, by the broader yellow postdiscal spot and the brown, not metallic blue abdominal end. Brazil (Rio Madeira).

H. meldolae *Btlr.* (= *bellatrix* var. *Wkr.*) (16 g) differs from *bellatrix*, particularly the form *aucta*, *meldolae.*
which it approximates greatly, by the very extensive spread of the red colour on the forewings; furthermore, the two upper spots of the yellow postdiscal macula small, the two lower ones large and moved more towards the margin. In Panama, Venezuela and Trinidad, apparently not rare.

H. bellatrix *Wkr.* (16 f) exhibits on the blackish-brown body metallic blue spots on the forehead, *bellatrix.*
neck, collar, metathorax and at the abdominal sides beginning from the 3rd ring. The base of the shoulder-covers and the two first abdominal rings above cream-coloured. The four pale yellow postcellular spots are arranged in one row. In the typical form the forewings are coloured exactly like in *amazonica*. — f. **columbiae** *columbiac.*
Btlr. has a considerably larger yellow postdiscal spot, the red spots on the hindwings stay separated, the yellow of the proximal margin is greatly reduced. — In f. **aucta** *form. nov.* (= ab. 2 *Hmps.*) (16 g) which is before me *aucta.*
from Muzo, the red colour is broadened from the median to the proximal margin and parted only by the black vein 1. In the specimen before me there is besides a yellow cuneiform spot in the base of the cell of the forewing; on the hindwings the red spots are larger and broadly flown together. — From Colombia (Bogotá) and Venezuela (Aroa).

H. cepheus *Cr.* (16 g) is characterized by 3 yellow abdominal rings which are dorsally interrupted; *cephus.*
the under surface also shows a yellow band at the 4th segment; laterally there are metallic blue spots. Forehead, shoulder-covers and forehips usually with yellow spots. Forewings with a metallic blue spot at the base and 2 at the transverse vein; short carmine stripes are at the base below the costa and median as well as at the

base of the lower median vein. In the cell-end an obsolete grey spot and 4 larger ones behind it, the two lower ones of which are moved more towards the margin. The hindwings exhibit large red spots below and behind the cell. Expanse of wings: 64 to 72 mm. Trinidad; Venezuela; Surinam. — It is open to doubt whether a form from Colombia (Medina, FASSL) lying before us in one ♂ example is to be taken as a subspecies to *cepheus*, or rather to be regarded as a distinct species: — *oculea* (subsp. nov. ?) (16 h) above all differs by a quite yellow cell of the forewing, in the centre of which there is a jet-black round spot. Between 2 reddish submedian stripes there is on the fold a black, bent stripe, behind which there is a reddish yellow spot. Veins towards the margin somewhat lighter. Forehead, collar and forehips yellow. The 3 first abdominal rings exhibit large dorsal, metallic blue spots, so does the last ring. The red spots of the hindwings are very extensive.

monticola. **H. monticola** Klages likewise resembles *cepheus*. Blackish-brown, on the forehead and shoulders yellow-brownish, on the vertex, collar, metathorax and chest blue spots. Forehips spotted yellow. The 1st abdominal ring exhibits dorsally and subdorsally 2 yellow-brownish spots each, the 2nd and 3rd ring with subdorsal yellowish transverse bands, on the 2nd ring dorsally a metallic blue spot, beginning from the 2nd ring there are lateral and sublateral blue spots; on the ventral side from the 2nd to 4th rings yellow transverse bands. Forewings at the base and transverse vein blue; subcostally, submedianly, in the cell-end and below the base of the lower median vein striped carmine with a brownish dusting; the postdiscal spot and hindwings like in *cepheus*. Expanse of wings: 62—66 mm. Venezuela.

boliviana. **H. boliviana** Druce (16 h) is easily recognizable by the yellow abdominal rings being not on the 1st and 2nd segments, but on the 2nd and 3rd, and being interrupted on the dorsum at their posterior margin by blue spots. Forehead and base of shoulder-covers exhibit yellow spots. In the cell-end of the forewing there is a large yellow spot being two-pronged towards the base, in the submedian space two extinct, yellow-reddish, bent, stripe-like spots. The lowest macula placed outwardly of the postdiscal spot is the smallest. Bolivia.

peruviana. **H. peruviana** spec. nov. (16 h) approximates *boliviana* by being also yellow on the 2nd and 3rd rings, but the segments are broad and uninterrupted. The forehead is black, the shouldercovers in the whole upper half yellow. Beside the red stripes being arranged like in *bellatrix*, on the forewings, the basal half of the cell exhibits yet a fourth. At the cell-end there are, as usually, 2 blue dots. The yellow postdiscal spot is small and narrow and extends only from 4 to 7. The hindwings are almost quite pale red with an irregular brown border and brown costal-marginal spot. Behind the yellow rings the abdomen is above entirely metallic blue. One ♂ from Peru (Cuzco), BANG-HAAS.

falerina. **H. falerina** Druce. The body is black, the abdomen with a metallic blue reflection, also the head and neck with blue spots. Forewing in the basal half quite red, with black stripes; at the base and cell-end metallic blue spots, and behind the cell a broad, yellow oblique band. Hindwings quite red with a black marginal band, which grows broader at the apex and at the middle of the distal margin. Expanse of wings: 72 mm. Peru (Marcapata).

maon. **H. maon** Druce (16 h), as *imaon*) differs from *imaon* by the normal shape of the wings and more intensely prominent red stripes on the forewings. Bolivia.

amazonica. **H. amazonica** Btlr. (16 i) is characterized by a bent, narrow, red stripe in the submedian area, a narrow red costal stripe and a mostly quite obsolete inner-marginal stripe, a large yellow postdiscal spot extending from the proximal margin almost to the distal margin, and like in the allies by a quite brown, blue-spotted body without any yellow markings. The hindwing, in the nomenclatory type, exhibits a large red postcellular spot, which is reduced and parted into two small ones in — f. *inferioris* Btlr. Amazon; from the Coll. FASSL there is before me a typical ♂ from East Colombia (Villavicencio, 400 m).

proserpina. **H. proserpina** Hbn. (16 i) differs from the preceding by a quite obsolete carmine spot in the cell-end and a lower one below the rise of the 2nd median vein. The yellow spot in the cell-end is absent. Amazon; Peru.

glaucozona. **H. glaucozona** Druce (16 i) is well recognizable by the peculiarly greyish-yellow tint of the postdiscal spot. The abdomen is like in the preceding without any yellow rings. On the forewings there is only little to be noticed of red markings; in the middle of the cell there is a reddish spot being divided in two at the end. Veins and submedian fold are striped somewhat darker. On the hindwings a large red postcellular spot. Amazon.

excreta. **H. excreta** spec. nov. (16 i). Closely allied to the preceding; at first sight discernible by two red spots on the hindwings. The forehead and base of the shoulder-covers are spotted yellow; the blue lateral spots at the abdomen are very large; the ventral side of the two first segments is spotted yellow. The veins are not darker striped; in the middle of the cell there is a square reddish spot; below it in the submedian space two reddish spots touching each other outside with the tips. The yellowish grey band behind the cell has a somewhat different shape. Described according to a ♂ from Peru (Tarapoto, BANG-HAAS).

tina. **H. tina** Wkr. (= *batesi* Fldr.) (17 a) is a greatly deviating, little species with narrow wings and a black body with intensely metallic greenish-blue spots. The blackish-brown forewings, with greenish-blue stripes subcostally and in the cell, exhibit behind the cell a broad, orange transverse band. Amazon (Rio Grande do Sul, Olivença).

54. Genus: **Agyrtidia** *Hmps.*

This genus containing one of the largest of all the Syntomids known hitherto, is characterized by a woolly haired thorax, broad wings in which all the subcostal veins stand on a joint pedicle. The 1st radial rises below the cell-angle, the lower radial veins separately. On the hindwings the lower median and lower radial veins stand on a joint pedicle.

A. uranophila *Wkr.* (17 a) is easily recognizable by the size and the metallic blue bordering of the *uranophila*. large hyaline spots. The black abdomen exhibits a metallic blue dorsal band, similar, though profusely white-dusted subdorsal stripes and an entirely white underside. Brazil, Peru and Bolivia (Coroico).

55. Genus: **Macrocneme** *Hbn.*

This genus contains numerous species of mostly very similar insects difficult to discern, of black colour decorated with blue and green metal-colours and very characteristic by the long hindlegs the tibiae and tarsi of which are provided with more or less long-haired scales. The erect palpi extend beyond the head. The antennae with a thickened median part are in the ♂ long-combed, in the ♀ mostly serrate-dentate. The nervation does not offer any peculiarities. As to the biology, comp. the General Topics (p. 36).

M. cyanea *Btlr.* (17 a) resembles the following species, but it has quite blue forewings except the *cyanea*. apex. Brazil (Rio de Janeiro); also from Peru.

M. lades *Cr.* (= *leucostigma* *Perty*, *naja* *Burm.*) (17 a). Easily recognizable by the white tips of *lades*. the posterior tarsi and the expansion of the bluish-green colour on the forewing, extending only as far as the cell-end and being crossed by an oblique, velvety-black band near the base. The golden green abdomen exhibits at the base above 2 white dots, the ventral side being spotted white. A very common species, widely distributed from Mexico to Peru and Argentina. — ab. **ferrea** *Btlr.* has a metallic blue abdomen, the black oblique band *ferrea*. separating the blue basal colouring from the disc is reduced. Described from Espiritu Santo. — In specimens from Peru: **chionopus** *form. nov.* — the hairy cover of the whole posterior tarsi is white. *chionopus*.

M. cupreipennis *Wkr.* (17 a) is a larger species easily recognized by coppery lustrous, golden green *cupreipennis*. colour covering the whole insect. The tips of the antennae are white, and so are also dots on the forehead, collar, base of palpi, forehips, base of femora, on the dorsum of the first abdominal ring and on the ventral side of the middle segments. Brazil, the exact habitat not being stated.

M. caeruleus *Dogn.* Palpal base in front white; on the forehead 2 white dots; collar with white *caeruleus*. dots and single blue scales. Abdomen black with a metallic green reflection, on the 1st ring 2 lateral white dots. The venter exhibits in the middle a series of white dots. The legs are black with blue scales, at the joints dotted white. The black forewings are in the basal half between the veins of a radiant metallic bluish-green, so are the hindwings in the disc. Expanse of wings: 37 mm. Venezuela (Merida).

M. semiviridis *Druce.* Anterior body black, tips of antennae white, abdomen and legs bluish-black; *semiviridis*. the first abdominal ring with lateral white spots; the venter exhibits a middle row of white spots. Forewings black, in the basal half between the veins metallic bluish-green; hindwings bluish-green with a broad black margin. Expanse of wings: 50 mm. Colombia.

M. nigricornis *Schrottky* has a black body with a green reflection, and white spots on the collar, pro- *nigricornis*. thorax, first abdominal ring (subdorsally), chest and the two first ventral segments. Forehips dark blue. Wings above with a faint metallic green lustre, beneath dark brown. Expanse of wings: 33 mm. Argentina.

M. adonis *Druce* (17 b). Discernible from the similar species with quite black tarsi by the extension *adonis*. of the blue colour on the forewing reaching almost to the margin, here mostly with an intense violet lustre. A golden green stripe at the proximal margin extends as far as the base. A metallic blue spot on the hindwing is usually more strongly developed than in the allies. Distributed from Mexico to Panama. — The example figured in the Biologia from Chiriqui has no blue in the apical part, but instead a blackish stripe runs from there to the transverse vein (= ab. 1 *Hmps.*).

M. cinyras *Schaus* (17 b) differs from the very closely allied *adonis* by the blue colour of the forewing *cinyras*. not forming an extensive surface, but consisting only of stripes between the veins behind the cell from vein 5 down as far as the proximal margin. In the discocellular itself there is only a narrow blue stripe near the upper end. Described from Mexico (Jalapa, Coatepec).

- chrysitis*. **M. chrysitis** Guér. (= *iole* Druce) (17 b). Most similar to *lades* (17 a), distinguished by the quite black tarsi and the more golden green, not so blue colour, and usually larger size. The black oblique band near the base is considerably narrower. Likewise widely distributed and common from Mexico to Rio Grande do Sul.
- deceptans*. — **deceptans** form. nov. (= ab. 1 *Hmps.*). Specimens from Guatemala and Rio Grande do Sul occasionally exhibit some white colour at the extremest tips of the posterior tarsi.
- laconia*. **M. laconia** Druce (17 b). The wings are unicolorously black, only at the base there are some metallic blue scales. Forehead, vertex, collar, sides of thorax, and hips are metallic blue. The black abdomen shows on the dorsum and at the sides likewise blue spots, the first two segments being ventrally margined with blue. From Mexico and Guatemala.
- nordina*. **M. nordina** Schaus looks very much like the preceding. Body black; outside of the palpi, spots on the forehead and vertex, as well as the forehips metallic bluishgreen, of the same colour are spots on the mesothorax; at the sides of the abdomen a broad, metallic green stripe. On the black forewings there is at the base of the proximal margin a metallic bluish-green stripe. Expanse of wings: 35 mm. Distributed in Mexico (Guadalajara, Zacualpan, Cuernavaca). — In specimens from West Mexico (Guerrero) there may occur orange colouring on the collar and posterior tarsi: **atilis** form. nov. (17 b).
- maroniensis*. **M. maroniensis** Schaus has a black body; the base of the femora, and forehips are white, ventral valve margined with white. The venter exhibits 2 rows of white spots. On the head and thorax there are dispersed blue scales; behind the eyes in the distal half of the collar and on the shoulders white dots. The wings are black, the forewings lighter towards the apex. Expanse of wings: 24 mm. French Guiana.
- evelina*. **M. evelina** Druce (17 c) is the only *Macrocneme* exhibiting above on the forewings a large white apical spot; the blackish-brown ground-colour turns somewhat lighter brownish towards it. Forehips and base of proximal margin of the forewing with metallic blue spots. Tips of antennae white. Occurs in Mexico and Panama.
- immanis*. **M. immanis** *Hmps.* (17 c) is the largest species and differs from the similar ones by its quite black thorax and the absence of the basal white dots of the forewing. Both the wings are uninterruptedly bluish-green as far as beyond the cell. Bolivia, also from Ecuador.
- thyra*. **M. thyra** Möschl. (17 c) is much smaller than the preceding and besides different by its metallic green, not black thorax, and white basal dots of the forewings; the green colour of the basal half is interrupted by a black oblique spot below the base of the cell. On the under surface the proximal margin of the forewing and the base of the hindwing are white. Chest and venter are white in their whole extent. Expanse of wings: 38 mm. Guiana, Brazil to Peru. From Colombia and Trinidad there originates a form with an uninterrupted green basal part of the forewing and without any white beneath: **intacta** subsp. nov. (= subsp. 1. *Hmps.*). — In **boliviana** **viana** subsp. nov. the green colour of the wings extends as far as the margin. Bolivia (Rio Songo).
- thyridia*. **M. thyridia** *Hmps.* (17 d) has, like the preceding, a coppery lustrous abdomen, but is immediately discernible from it by its entirely black, and not white; under surface exhibiting only a middle row of minute white spots. The forewings exhibit like in *chrysitis* and *lades* a black oblique band in the basal third; the greenish golden colour occurring also on the under surface, is not spread far and varies greatly by being brassy golden to copper-coloured. The bases of all the wings are to a small extent whitish beneath. Surinam, Venezuela.
- affinis*. **M. affinis** Klages differs from the preceding by its black thorax being subdorsally striped metallic blue, and blue-striped shoulder-covers being in the ♀ not bordered with white. Forehips and posterior tibiae striped blue, the latter without any white at the ends. Abdomen like in *thyridia*. The forewings, with only 1 white dot at the base of the costa, are striped metallic blue, not green. Expanse of wings: 36 mm. Venezuela.
- maja*. **M. maja** F. (17 c). Black; tips of antennae white; forehead, palpal base, collar, chest, forehips and 1st abdominal ring dorsally with white dots. The abdomen shows subdorsal, metallic green stripes, lateral and ventral rows of white dots. Forewing in the distal half as far as the margin suffused with metallic bluish-green, frequently with continuations towards the base below the median and at the proximal margin; at the base 2 white dots. Hindwings with a bluish-green apical spot. Expanse of wings: 38 mm. Surinam; Amazon (Pará).
- guyanensis*. **M. guyanensis** Dogn. Black, thorax and abdomen with a green lustre; palpal base, forehead and collar dotted white, so is the 1st abdominal ring subdorsally and sublaterally. Ventral valves black, on each side with a white dot. Venter quite black with single green scales. Hips black. Wings black, with subcostal green stripes, also below the median and at the proximal margin; in the disc of both wings metallic blue scales. Expanse of wings: 31 mm. French Guiana.
- cyanescens*. **M. cyanescens** Dogn. Body black; forehead, collar, shoulder-covers, thorax, hips and legs with metallic green spots. The abdomen shows dorsal, subdorsal, and sublateral green spots; ventral valve metallic green. Wings black with a deep violettish-blue lustre, at the base a little metallic green. Expanse of wings: 42 mm. East Colombia.

M. misitra *Schaus* (17 c) has the most thinly scaled wings, and a collar spotted orange-red, whereby *misitra*. it is easily recognized from among the species with yellow hindfeet; like in the following species, the ventral valve of the ♂ is margined with orange. The abdomen shows dorsal and lateral rows of blue spots. Mexico (Paso de San Juan, Vera Cruz).

M. laciades *Schaus* (17 d). The ♂ exhibits, like in the preceding species, a ventral valve margined *laciades*. with orange, the anal apex being orange, too. The collar is quite black, the base of the yellow hind tarsi is likewise black; the black wings are a little more densely scaled. From Mexico.

M. auripes *Wkr.* (17 d) differs from the allied species with yellow hind tarsi at once by the golden *auripes*. green stripes in the middle part of the costal margin and cell of the forewing. The ventral valve of the ♂ is bordered with white like in the following species. The ventral part of the ♂ exhibits sublateral white spots on the middle segments. Distributed in Honduras, Guatemala, Costa Rica, Panama and Colombia.

M. jalapensis *Schaus* (17 d) has, like *auripes*, the ventral valve bordered with white but it is immediately *jalapensis*. discernible by the quite black wings turning somewhat lighter brownish towards the apices of the wings; only the base of the proximal margin of the forewing exhibits a tiny blue spot; forehead, collar, shoulders and hips are spotted metallic blue, so are the abdominal sides. Mexico (Jalapa).

M. chrysotarsia *Hmps.* (17 d). Among the species with yellow posterior tarsi, this species exhibits *chrysotar-* the greatest extension of the golden green colour on the forewings, spreading as far as behind the cell and *sia*. down to vein 1. The ventral valve of the ♂ is besides bordered neither with orange nor with white, but laterally spotted metallic blue. Panama, Venezuela. — This species also occurs in Venezuela with quite black tarsi.

M. indistincta *Btlr.* (= *splendida* *Btlr.*, *cyllarus* *Druce*) (17 c) differs from the species with white *indistincta*. tarsi of the *lades*-group by the posterior tibiae being set with hair only on one side (above); the forewings, being suffused with bluish-green, have a black basal part; only the extreme base shows two fine, metallic blue dots. The fringes are coloured white at the proximal angle of all the wings. The abdomen is suffused with green, not striped. Widely distributed from Panama to Brazil. — **hampsoni** *Schrottky* (= *indistincta* ab. 1. *Hmps.*) *hampsoni*. has quite black fringes, and the golden green colour of the forewings is more extensive, particularly at the proximal margin. Paraguay.

M. caurensis *Klages* is somewhat smaller than *alesa* (17 d), the palpi are white at the base and anterior *caurensis*. side of the 2nd, sometimes also of the terminal joint. On the collar, shoulders, meso- and metathorax and forehips there are white spots of a blue opalescence, the shoulder-covers and tibiae being striped white and blue. On the forewings there is golden green colour also in the cell, whereas on the inner-marginal vein it is absent. All the rest like in *alesa*. Expanse of wings: 30 mm. Venezuela.

M. alesa *Druce* (17 d). The smaller size and the expansion of the golden green colour at the costal *alesa*. margin of the forewing almost as far as the apex and on vein 1 separate this species from the very closely allied *vittata*. From *indistincta*, which it nearly resembles still more, it is distinguished by its much smaller size as well as by the abdomen being only dorsally and laterally striped green, not entirely suffused with golden green. Peru and Bolivia.

M. vittata *Wkr.* (17 d) is somewhat larger than *alesa*, and the green colour is not so extensive; in the *vittata*. ♂ the front side of the palpi is white. The shoulders show blue and white spots, the shoulder-covers such stripes. The fringes of all the wings are often white towards the proximal angles. From Venezuela and the Amazon (Pará).

M. esmeralda *Btlr.* (17 e) likewise greatly approximates the preceding species, but it has the abdomen *esmeralda*. entirely black beneath without any white spots, with dorsal, lateral and sublateral golden green stripes. The golden green colour is spread almost over the whole forewing, only the margins and veins remain black. Panama (Amazon).

M. albitarsia *Hmps.* (17 e) is one of the smallest *Macrocneme* with unicolorously black body and *albitarsia*. wings; metallic blue, small spots are to be noticed on the forehead, collar, shoulder-covers, thorax and hips, as well as on the sides of the abdomen and at the extreme base of the forewing. The apices of the wings and the terminal joints of the posterior tarsi are white. — From the Amazon.

M. hesione *Druce* (17 f) somewhat resembles *evelina* by the lighter apex of the forewing, being beneath *hesione*. all white; the veins remain black; the other parts of the animal are black, on the forewings with a purple lustre; anus and ventral side of the abdomen metallic green. Panama.

M. nigratarsia *Hmps.* (= *vittata* *Druce*) (17 e) looks rather like *vittata*, but it has quite black posterior *nigratarsia*. tarsi. The green colour is confined on the forewings, on vein 1 it is altogether absent. The ♂ has the ventral valve margined with white, but no white ventral spots, whereas the ♀ exhibits such on the two middle segments, one ♀ from Trinidad on 4 segments. From Mexico (Tabasco), Guatemala and Trinidad.

M. eacus *Cr.* (= *errans* *Hbn.*, *pusilla* *Btlr.*) (17 e) is quite unicolorously bluish black; at the palpal *ecacus*. base, behind the eyes, on the collar and shoulders small bluish-white spots. On the chest and sides of the abdomen single metallic blue scales. At the base of the forewing is a white dot; middle area with a more intense blue lustre. Expanse of wings: 32 mm. Surinam; Pará.

sura. **M. sura** *Schaus.* Palpi and legs black, suffused with metallic blue; posterior tarsi with white ends. Head black, on the forehead 2 large white spots, smaller ones below the antennae. The collar exhibits blue and white spots; thorax black, shoulder-covers anteriorly spotted blue and white. Abdomen above metallic green, beneath black, ventral valve green; the middle of the venter exhibits 2 rows of small white spots. Forewings dull metallic bluish green, a subbasal band and the distal margin black. Hindwings black. Expanse of wings: 35 mm. This species described from Brazil has remained unknown to me.

viridifusa. **M. viridifusa** *Schaus.* Head and thorax greenish black, the collar outside and inside bordered with white. Abdomen dull green with 2 white lateral spots at the base; a white ventral spot; hips spotted white; legs greenish black. Forewings brownish black with dark green veins, costal and proximal margins. Expanse of wings: 38 mm. Castro (Paraná).

56. Genus: **Phaco** *Newm.*

Animals with very long and narrow wings, with a woolly thorax and abdominal base. On the forewings the 1st median vein rises before the lower cell-angle from which the 2 lower radial veins rise, the uppermost from the cell. On the hindwings the lower median and lower radial vein are petioled, the 1st median vein rises from the upper one close before the margin.

cephalena. **Ph. cephalena** *Druce* (17 e). Head and thorax are black with white dots on the head, collar and shoulders; the abdomen is metallic bluish-green with white lateral stripes and a white band across the first segment. The blackish-brown wings being provided with hyaline spots exhibit in the basal part of the forewing a golden green spot, between the lower median and lower radial vein a more bluish-green, large spot. The antennae exhibit above a trimming of scales. Colombia, Ecuador.

quadriguttata. **Ph. quadriguttata** *Dogn.* (17 e) greatly resembles the preceding and is to be distinguished by the very long-stretched submedian hyaline spot, by the absence of the spots between the lower radials and below the 1st radial vein as well as by the much greater extent of the golden green scaling on the forewings; on the hindwings there is another minute hyaline spot between the upper median and lower radial vein. Ecuador and Colombia.

aquiguttata. **Ph. aquiguttata** *Dogn.* (17 f) has a black body: forehead and prothorax are metallic greenish-blue; each half of the collar exhibits a large, round, white spot, a similar, very large one with a greenish-blue iridescence on the metathorax. The first abdominal ring exhibits 2 large white dorsal spots, the other rings show greenish-blue bands, the angular membrane is yellowish-white. The brown forewings exhibit below the median a large oval hyaline spot, above it in the cell a cuneiform spot and at the upper cell-angle a minute punctiform spot; behind the cell an oblique band of 5 hyaline spots, the middle one being very small, in the shape of a streak, the two lower ones moved towards the margin. The hindwings being hyaline in the disc exhibit a black margin. From Columbia, also from Ecuador.

geminiguttata. **Ph. geminiguttata** *Dogn.* (17 f) is not to be confounded owing to the hyaline double spots being peculiarly placed behind each other on the fore- and hindwings; the forewings are strewn with golden green scales. Head and thorax are black, on the forehead, collar, shoulders, meso- and metathorax white spots. The first black abdominal ring exhibits white dorsal and lateral spots, the rest is metallic greenish-blue with white lateral stripes quickly narrowing down posteriorly. The ♂ antennae are above thickly covered with metallic greenish-blue scales. Colombia (San Antonio; Medina).

sylva. **Ph. sylva** *Schaus* (17 f) from Brazil (Rio de Janeiro), before us also from Colombia, is a smaller species, the wings densely strewn with golden and coppery lustrous scales and with hyaline spots arranged about similarly as in *cephalena* (17 e), though those being situate towards the costal margin are very small. The abdomen, with a golden green lustre, has on the first segment a white transverse band, on the other segments bluish-white lateral and sublateral spots. — From Colombia (coll. FASSL) there is a form before me: **impellucida** *form. nov.* (17 f), in which all the hyaline spots of the forewings are absent, whereas on the hindwings they are present.

salmoni. **Ph. salmoni** *Druce* (17 g) by the arrangement of the hyaline spots resembles *quadriguttata*, though they are all much smaller. Head and thorax are black, collar and shoulders spotted white; the metathorax exhibits a very large, round, white spot. The golden green abdomen with a black dorsal stripe exhibits on the second ring large white spots, on the black under surface there are broad white sublateral stripes. Colombia.

albicincta. **Ph. albicincta** *Schaus* (17 g). Head and thorax are black; the shaft of the antennae blue. Collar, hips and spots at the posterior femora, the 2 first abdominal rings and the whole ventral side are white; the abdomen otherwise metallic blue, anal tuft black. The black wings are strewn with small, silvery blue scales and the hindwings exhibit below the cell a large oval hyaline spot. Expanse of wings: 46 mm. Ecuador.

Ph. unimacula *Rothsch.* (17 h) differs from the preceding, similar species by the more coppery golden *unimacula*. scaling of the wings, by the black, white-spotted collar, the black, white-spotted two first abdominal rings, the greenish coppery other segments with black ring-indentations and dorsal line; the segments 3 and 4 show bluish-white lateral spots, the last ring subdorsal white spots. Described from Peru. The species also looks very much like *impellucida* (17 f), the form of *sylva* described above.

Ph. bacchans *Schaus.* Body black; tips of antennae and ends of tarsi white. The basal joint of the *bacchans*. antennae, vertex, collar, shoulders and metathorax show white dots. Legs striped blue. The abdomen shows dorsal, lateral and sublateral rows of white and blue dots. The black forewings are in the larger basal halves suffused with golden green, with a white dot at the base. Hindwings black with a green spot behind the lower cell-corner. Expanse of wings: 46 mm. Peru.

Ph. pinocha *Dogn.* differs from the preceding by its entirely black abdomen with metallic green lateral *pinocha*. stripes and only beneath some white dots, as well as quite black antennae. The hindwings are velvety black, dusted metallic green along the costal margin, and at the proximal margin with some metallic blue scales. All the rest as in *bacchans*. Expanse of wings: 34 mm. Ecuador (Loja).

Ph. aurata *Schaus.* Body black; forehead, vertex, collar and shoulders with white dots; on the meta- *aurata*. thorax there is a light golden spot. Hips and posterior tibiae spotted white. The 2 first abdominal rings exhibit subdorsal white spots, the others yellow spots; a sublateral row of spots and the ventral side are yellow. Wings black, suffused with golden yellow. Expanse of wings: 46 mm. Peru.

Ph. caeruleonigra *Schaus* (17 g). Head and thorax bluish-black, the abdomen more greenish-blue. *caeruleoni-*
The articular ends of the legs, forehips, sides of the forehead, and hindhead exhibit white dots. Wings silky *gra*. lustrous blackish grey with a dark blue reflection. Expanse of wings: 36 mm. Peru.

Ph. longipennis *Neum.* The access to the description of this species was not possible. *longipennis*.

57. Genus: **Chrysocale** *Wkr.*

Large species with a magnificent golden green and coppery lustre, the ♂ with long-combed antennae and erect palpi. Thorax and abdominal base covered with long hair, and with lateral hair-tufts on the last segments. In contrast with the preceding genus, the two upper subcostal veins on the forewing rise from the cell.

Ch. principalis *Wkr.* (17 g). Head and thorax black; palpal base, forehead, vertex, collar, sides of *principalis*. thorax, and hips with white spots. Abdomen with golden green bands warming towards the anal end by copper into metallic carmine, the ventral side with white transverse bands. Forewings black, in the basal third with a large, golden green spot; from the cell-end to the proximal angle extends a large green spot with a somewhat more coppery lustre, and in the apical third there are green stripes noticeable between the veins. A small hyaline spot in the middle of the cell, a larger one below it; at the cell-end a small spot and four behind it. Hindwings black with a blue reflection and 2 hyaline spots. It is found in Mexico and Guatemala.

Ch. regalis *Bsd.* (17 g) resembles the preceding, though it is somewhat smaller and all the white *regalis*. spots are smaller, the one in the middle of the cell being absent; besides, the white spots are absent on the collar and shoulder-covers; the cell-end is quite blackish-blue, the abdomen unicolorously bluish-green. Colombia, Ecuador, Argentina. — ab. **quadripunctata** *Dogn.* from Ecuador (Loja) has on the forewings only 3 small hyaline *quadripunc-*
spots, on the hindwings only the one at the base. *lata*.

Ch. plebeja *H.-Schäff.* (= *opulenta* *Wkr.*) (17 k) looks something like *ignita* (17 i), but without any *plebeja*. hyaline spots. The body is black, with a slight coppery lustre. Forewings metallic green, at the costal and distal margins black; the parts below and behind the cell more coppery lustrous. In the middle of the cell there is a black longitudinal spot, from the inner corner of which a black stripe runs vertically to the proximal margin. Hindwings bluish-black. Expanse of wings: 56 mm. Venezuela.

Ch. gigantea *Druce* (17 h). Forewings greenish lustrous, before the middle more copper-coloured, *gigantea*. with a black discal part, two antemedian and 5 postmedian hyaline spots; the green hindwings exhibit a large hyaline spot below the cell and 3 spots between the lower median and 1st radial vein. The body is blackish-brown, the abdomen spread with golden green; palpal base and forehips spotted white. Ecuador and Colombia.

Ch. splendens *Dogn.* (17 h). Body brownish-black; head, mesothorax and legs with a green metallic *splendens*. lustre; forehead and forehips white. The abdomen exhibits on the middle rings 3 metallic green dorsal spots; the 3 last rings and the venter quite green; on the middle rings 2 white lateral spots. Wings metallic green with a coppery lustre. Behind the middle of the costa a triangular black spot extending down as far as the 2nd median. Proximally to it in the cell a small hyaline spot, another one in the upper cell-corner, and a third is situate between the 2nd median and 4th radial, and a small one above the upper radial vein.

The marginal area is black, the hindwings black with a metallic green antemarginal band. Expanse of wings: 50 mm. Ecuador (Loja).

ignita. **Ch. ignita** H.-Schäff. (17 i). On the bluish-black body the collar, shoulder-covers and mesothorax are copper-coloured. The forewings exhibit at the base a metallic grass-green spot distally bordered by a straight black stripe, behind it a coppery lustre is spread. The middle of the cell, distal margins, and hindwings blackish-blue; two hyaline spots are in the middle and at the end of the cell. Venezuela, Colombia, Brazil.

ferens. **Ch. ferens** Schaus (17 i) initiates a small group of species without any hyaline spots with unicolorously metallic green wings. The body is black, palpal base, forehead, collar and shoulders spotted white. The abdomen exhibits dorsal, lateral and ventral rows of bluish white spots, the 2nd and 3rd ring small, unscaled, ochreous-yellow subdorsal spots. Bolivia, Peru. — subsp. **quadruplex** Dogn. is somewhat smaller and shows on the fore- and hindwings below the median one small, triangular hyaline spot and, according to HAMPSON, does not differ from *ferens* with respect to the species. Described from Colombia.

corax. **Ch. corax** Hmps. is a very large species with jet-black, velvety hairs on the body. The wings, and abdomen laterally and beneath are metallic dark bluish-green. Forehead and vertex with a blue lustre. Expanse of wings: 54 mm. Peru.

gigas. **Ch. gigas** Rothsch. (17 h) is considerably larger than the preceding from which it differs besides by white posterior tarsi; as for the rest, the legs are blackish-brown, hips and tibiae metallic blue; head and collar black with metallic blue spots; the black abdomen exhibits lateral metallic blue spots. Peru, Ecuador, Colombia.

58. Genus: **Calonotus** Hbn.

Medium-sized species with black wings with or without hyaline spots and the abdomen striped metallic golden or green, the ♂ with doubly combed antennae. On the forewings the upper median vein rises from the lower cell-corner; both the lower radial veins are, in their proximal course, very near to each other; the two uppermost subcostal veins rise separately from the cell. The cell of the hindwing is large; from its upper angle the subcostal and 1st radial veins rise unpetioled. — The species greatly approximate each other, owing to their considerable variability, so that we are not yet able to exactly define the species and subspecies by means of our present knowledge.

metallicus. **C. metallicus** Druce (17 i) is recognizable by the concavely indented distal margins of all the wings. The black body exhibits orange golden spots on the meso- and metathorax, the abdomen similarly coloured broad dorsal and lateral stripes. At the base of the forewing an orange golden spot, behind it a minute hyaline spot; a large, round hyaline spot is behind the cell, the hindwings exhibit one hyaline spot. Costa Rica, Panama.

tiburtus. **C. tiburtus** Cr. (17 i). The bluish-black body exhibits metallic coppery spots on the meso- and metathorax, similarly coloured dorsal and lateral stripes on the abdomen. The blackish-blue forewings exhibit below the middle of the cell and behind the cell one hyaline spot each, the ♀ has besides a third spot between the median veins. The hindwings exhibit a postcellular hyaline spot. Distributed in Costa Rica, Panama, Venezuela, Surinam. — A form from Trinidad, without any white spots on the thorax and palpal base, has *trinitatis*, been established as **trinitatis** Strand.

phlegmon. **C. phlegmon** Cr. (17 k) differs from the similar species by its considerable size and the presence of a mostly small hyaline spot below the base of the cell of the hindwing, beside the spot behind the cell; the forewings exhibit at the costal-marginal base likewise a small hyaline spot. Surinam, Pará, São Paulo.

chalcipleurus. **C. chalcipleurus** Hmps. (17 k) greatly resembles *tiburtus*, but it is at first sight discernible by the golden green colour. The wings are broader, the white hyaline spots smaller, the antennae of the ♂ longer combed; the spot between the median veins of the forewings is present also in the ♂; beside the green basal spot below the median there is also one at the costal margin; the first abdominal ring exhibits only 2 dorsal spots, no lateral ones as in *tiburtus*.

hoffmannsi. **C. hoffmannsi** Rothsch. (17 k). A small, insignificant species which, according to my opinion, is identical with *Paramya chrysonota*; the blackish-brown, very narrow forewings exhibit below the median a hyaline spot with a much smaller one below it, at the cell-end 2 hyaline dots, as well as above and below the lower radial vein a hyaline spot, the hindwing near the base one and in the disc 2 hyaline spots. The black abdomen is striped in a dull coppery colour on the dorsum and sides. The head is metallic green, the black thorax is spotted white on the collar and shoulders. Amazon (Itaituba).

triplagus. **C. triplagus** Hmps. (= *tripunctatus* Hmps. pt.) (17 k) is black; forehead, collar, sides of thorax, ends of femora, hips and first abdominal ring with small white spots; beginning from the 2nd abdominal ring there are broad, goldengreen, longitudinal stripes on the dorsum and sides, on the venter a white median stripe.

Wings like in the following, but with golden green stripes not only subcostally, but also below the base of the cell; a green blurred spot is also below the cell-end. Amazon.

C. tripunctatus Druce (18 a) greatly approximates the preceding species and differs by the absence of the white spots on the collar and base of abdomen; the abdomen exhibits dorsal and subdorsal broad, sub-lateral narrow silvery green, not greenish golden stripes. From Trinidad and St. Vincent. — The figure in HAMPSON's Cat. Lep. Phal. 1, t. 12. f. 7 refers to the present species, not to *triplagus*, as is assumed in ZERNYS Catalogue.

C. opalizans Rothsch. (18 a) forms the transition between the preceding species and *helymus*; the hyaline spots of the former have almost disappeared on the broad brown wings; the species is distinguished by the abdomen being entirely opalescent like mother-of-pearl. Venezuela.

C. helymus Cr. (= *aterrima* Sepp) (18 a) is in both sexes characterized by its entirely unspotted, dark brown, very broad wings. The abdomen exhibits broad, greenish golden dorsal and lateral stripes, on the ventral side a white stripe. French Guiana. — The larva lives on the coffee-tree and is anteriorly and posteriorly yellow, in the middle more greenish. The segments exhibit blue warts bearing on the 2nd and 3rd rings tufts of long, black hair being yellow at the end; the 8th ring exhibits above a pencil of long, black hair.

C. longipennis Rothsch. (18 a) has, like the preceding, unspotted forewings which, however, are much longer and narrower, quite black with a blue purple lustre, and exhibit metallic green basal spots below the costal margin and the median. Chest, forehips and the basal joints of the palpi are white. White spots are besides at the femoral ends, on the forehead, collar and first abdominal ring. Surinam.

C. aurata Wkr. (18 b) looks like a *Macrocneme*; body blackish-brown; tips of antennae white; at the palpal base, forehead, collar, shoulders, and chest white dots. The 1st abdominal ring exhibits dorsal and lateral, double, white dots, the 2nd ring only lateral ones; the first segments below white. Vertex and legs spotted golden green; femoral base posteriorly spotted white. The basal half of the black forewing is golden green. Expanse of wings: 40 mm. Venezuela.

C. chryseis Druce (18 a) is a very large species from Colombia and Bolivia with dorsal, lateral and sublateral golden spotted, not striped abdomen and thereby easily recognizable; the venter is striped white. The wings are in the ♀ unicolorously golden green; the ♂ exhibits round hyaline spots below the middle and in the end of the cell, behind the cell above the rise of the upper median vein, as well as a minute spot above the 1st radial; the hindwing shows hyaline spots below and behind the cell.

C. plumulatus Klages is, like the following, distinguished by extremely long-combed antennae. Blackish brown; forehead, collar, chest, forehips, and the ends of the middle and posterior tibiae with white dots. The abdomen shows, beginning from the 2nd ring, dorsal, lateral and sublateral, broad, golden green stripes, the 1st ring subdorsal, white streaks and lateral spots, the venter a middle row of small white spots. Forewings blackish-brown with metallic bluish-green stripes below the costa and median. Expanse of wings: 50 mm. Venezuela.

C. antennatus Rothsch. (18 b) has the hyaline spots of the wings placed the same as *tiburtus* (17 i); the basal spot of the forewing and the stripes on the abdomen are copper-coloured, like in the former, from which the ♂ is easily discernible by the extraordinarily strongly combed antennae and the hyaline spot between vein 2 and 3; the ♀ differs almost only by somewhat narrower wings and smaller spots. Venezuela.

59. Genus: **Poliopastea** Hmps.

Small to medium-sized species, resembling on the whole by their exterior the unspotted species of the preceding genus, from which they differ by the porrect palpi and by the normal course of the lower radial veins of the forewings.

P. pava Dogn. (18 a). Head and thorax bluish-black; first palpal joint, forehead and collar with double, bluish-white dots; forehips spotted bluish-white. Posterior tibiae strongly thickened, without any spurs, with a long, ochreous yellow hair-tuft and thickly scaled tarsi. The abdomen exhibits unsealed, ochreous-yellow ring-indentations, lateral and dorsal white dots. Forewings black with a green lustre. Hindwings bluish-black with a cuneiform hyaline spot, being bifid at the end, below the cell at the base. Expanse of the wings: 54 mm. Venezuela (Merida).

P. viridis Druce (18 b) has grey wings with an intense green lustre, the veins with a blue lustre. Head and thorax are black; the second palpal joint, hips and first joint of the tarsi spotted white. The abdomen is dark bluish-grey with a ventral row of white dots. Ecuador.

- ockendeni*. **P. ockendeni** *Rothsch.* (18 b). Distinguishable from the preceding species by its deep metallic blue, not green wings, with 3 white basal dots, bluish-white spots on the forehead and vertex, collar, shoulders, meso- and metathorax, quite black palpi, and metallic blue forehips. The abdomen is blackish-green with bluish-white dorsal and sublateral lines. British Guiana, Peru.
- rosenbergi*. **P. rosenbergi** *Rothsch.* (18 b) likewise approximates the preceding species, being considerably larger, the forewings in the basal half metallic green; the hindwings exhibiting at the base a small white transparent spot are in the costal half metallic bluish-green. Head and thorax black, spotted white; the abdomen is metallic green with a coppery lustre, on the first segment 2 white dots behind each other. Hips white. West-Ecuador.
- verdivittata*. **P. verdivittata** *Klages*. Black; forehead, neck, shoulder-covers, chest and joints of femora spotted white; golden green spots are on the collar and shoulders, meso- and metathorax. The abdomen exhibits broad, golden green dorsal, lateral and sublateral stripes, the lateral stripes begin at the 1st ring with white spots. The black forewings show, in the subcostal space at the base, a small hyaline stripe, below the base of the cell a broad, golden green stripe, and at the costal base a small white spot. Hindwings above black. On the under surface the cells of all the wings are striped green. Expanse of wings: 44 mm. Venezuela. — f. **fenestrata** *Klages* shows a hyaline spot below the middle of the cell and a series behind it between the upper median and lowest subcostal veins; the hindwing with a hyaline spot behind the cell.
- plumbea*. **P. plumbea** *Hmps.* (18 b). The smallest species with blackish-grey wings and body. Metallic blue, small spots are on the forehead and vertex, shoulder-covers, legs, the dorsum and sides of the abdominal rings and on the ventral valve of the ♂, which is besides broadly margined with white; the 4th ring exhibits a large white ventral spot, the next rings indistinct, white sublateral spots. The fringes are white at the proximal angle. Amazon; French Guiana.
- obscura*. **P. obscura** *Wallgr.* (= *nox* *Druce*) (18 b) is a unicolorously dark leaden-grey species. Tips of antennae white; collar, shoulders and legs, as well as the base of the forewing with metallic blue dots. The abdomen exhibits a lateral row of small blue spots. Expanse of wings: 34 mm. Ecuador and St. Lucia.

60. Genus: **Dinia** *Wkr.*

Three very characteristic species, particularly distinguished by the long, dense hair-tufts at the sides of the broad, flat abdomen, beginning from the 3rd ring as far as the large anal tuft. The broad wings are entirely transparent with black margins. The shaft of the antennae is greatly broadened in the middle and above hairy, doubly combed. The very large cell of the hindwing extends almost to the margin; the upper median vein and both the lower radial veins rise all separately.

- acagnus*. **D. aeagnus** *Cr.* (= *auge* *Wkr.*) (18 c). Blackish-brown, the hair-tufts of a magnificent brilliant carmine. The wings hyaline with narrow black margins and discoidal spots; at the base of the forewing there are two silvery lustrous blue dots, at the proximal margin a carmine stripe. Widely distributed and mostly common from Mexico to Argentina.
- mena*. **D. mena** *Hbn.* (= *saucia* *Wkr.*) (18 c) has no silvery blue dots at the base of the forewing, but instead there are carmine stripes also at the base of the costal margin and above vein 1. Likewise very common and distributed from Panama to Brazil, Peru and Bolivia. — **puniceocincta** *Strd.* is a form with carmine bands at the median segments of the abdomen.
- subapicalis*. **D. subapicalis** *Wkr.* (= *merra* *Wallgr.*) (18 c). In this species having become known hitherto only from Peru, the lateral hair-tufts and the anal tuft are black, the abdomen above with 3 carmine transverse bands. The marginal band of the hindwing is extremely broad; the basal part of the proximal margin of the forewing beneath, and the middle costal-marginal area of the hindwing above are orange.

61. Genus: **Paradinia** *gen. nov.*

The only species known hitherto representing a striking image of *Corematura chrysogastra* (18 g) is very closely allied to the genus *Dinia*; in the veins there is no remarkable difference; the whole animal is much more slenderly built, the abdomen not flattened, the lateral hair-tufts much less developed and flatly appressed. The antennae are not thickened in the middle and do not exhibit any hairy cover. Type: *P. chrysogastrides* *Draudt.*

- chrysogastrides*. **P. chrysogastrides** *spec. nov.* (18 c). The body is black. The forehead, a transverse stripe between the antennae, the neck, the sides of the collar, a middle line on the shoulder-covers and their distal hairiness

are ochreous-yellow as well as a middle line on the metathorax, being continued on the 2 or 3 first abdominal rings as triangular dorsal spots. Underneath, the otherwise black abdomen is curled orange-yellow; the lateral hairing and the underside of the anal tuft, being black above, is carmine. Antennae, palpi and legs are black, the inner side of the hips and femora striped ochreous yellow. The basal parts of the hyaline wings are ochreous yellow, carmine are stripes at the base of the costal margin, the median and along the proximal margin as far as near the anal angle. The margins of the forewings are narrowly, those of the hindwings broadly bordered with black. Described according to 2 ♂♂ from Colombia; type in Coll. DRAUDT.

62. Genus: **Mesolasia** Hmps.

Large, robust species, the exterior of which reminds us of *Homoeocera*-species, from which, however, they are easily discernible by the uncommonly large cell of the hindwing. Like there, the antennae are greatly thickened in the middle and exhibit here on the upper side a thick cover of hair. The upper median vein and both the lower radial veins of the hindwing rise all separately, the uppermost radial vein a little below the upper cell-angle.

M. haemorrhoidalis Stoll (*haemorrhusa* Hbn.) (18 c) is a very large, characteristic species easily recognizable by the carmine first and the 4 last abdominal rings. Occurring from British Honduras to Brazil (Rio de Janeiro). *haemorrhoidalis*.

M. paula Schaus (18 d) differs from the preceding by only the 3 last segments of the black abdomen being red. From the exteriorly very similar *Homoeocera lophocera* Druce it is easily discernible by the difference of the veins on the hindwings: *Homoeocera* has a very minute, *Mesolasia* an uncommonly large discocellular. Brazil (São Paulo). *paula*.

M. felderi Rothsch. (18 d) differs from the preceding species by its smaller size, a more graceful structure, and very much narrower black margins of the wings; the narrow, black discal spot only extends as far as the rise of the 1st median vein. From French Guiana and Brazil. *felderi*.

M. hampsoni Dogn. is black on the front body and the 5 first abdominal rings, the other rings are carmine, the anal tuft yellow. Wings like in the preceding, but with a larger apical spot of the forewing. Expanse of wings: 40 to 43 mm. Venezuela (Merida). *hampsoni*.

M. melanobasis Druce (18 d) is well characterized by the apical hyaline spots in the very broad marginal band of the hindwing. The black abdomen with 3 red terminal segments exhibits on the first ring a large dorsal spot, on the others small white ones. Brazil (São Paulo, Sa. Catharina, Paraná). *melanobasis*.

M. ornata Mén. (18 e). Head, thorax and the 3 first abdominal rings black; the anterior side of the palpi, the margins of the shoulder-covers and spots on the collar and the black abdominal rings are white. Beginning from the 4th ring, the abdomen is carmine with dorsal black, white-pupilled spots. On the ventral side two rows of white spots. Wings hyaline with black veins and margins, middle spot and apical spot; the proximal margins of all the wings striped yellow. Expanse of wings: 42 mm. Brazil (Minas Geraes). *ornata*.

63. Genus: **Trichura** Hbn.

A very characteristic genus, looking very much like Ichneumonids owing to the strangulated abdomen; in order to increase this impression, in single species the ♂♂ exhibit at the abdominal end a long, terebrac-like appendage consisting of soft hair and densely covered with scales. The hyaline wings are distinguished by the extraordinarily long cell of the hindwing, so that the transverse vein disappears in the black marginal band. All the veins rise separately. The shaft of the antennae is thickened in the middle and above covered with rough, hairy scales. HAMPSON's division of the species into such with, and such without an abdominal appendage is not maintainable, as in many species, such as *dixanthia*, *monstrabilis* etc., the ♂♂ sometimes occur with the appendage, sometimes without it.

T. cerberus Pall. (= *caudata* F., *urophora* H.-Schäff.) (18 d) has yellowish hyaline forewings with narrow black margins and a discoidal spot varying greatly in extent. The velvety-black abdomen with metallic bluish-green spots and bands has underneath a large, white basal spot and sublateral white macular rows. Widely distributed in Venezuela, Surinam, Brazil (Amazon, Rio de Janeiro, São Paulo) and Trinidad. — Specimens with particularly narrow black margins and discoidal spots, as they are before me from Bolivia from the Rio Songo, have been denominated: **angusta** Stgr. (i. l.?) (18 d). — This species exhibits the longest tail-appendage which may even grow longer than the whole body. *cerberus*. *angusta*.

- fulvicauda.* **T. fulvicauda** Lathy is at once distinguishable from the preceding by the orange-yellow tail-appendage; furthermore, the anterior side of the palpi, the forehips, the 3 first abdominal rings on the ventral side and sublateral spots on the 3rd ring are orange. On the yellow hyaline forewing there is below the median an orange-yellow basal spot. Paraguay.
- monstrabilis.* **T. monstrabilis** Klages. Body black, with metallic blue or green spots on the forehead, vertex, collar, shoulders, shoulder-covers, thorax and legs; anterior side of palpi, spots on the neck and forehips in the ♂ are white. The abdomen shows a bronze-green lustre, the strangulated segment is laterally and underneath white. The ♂ with or without a long tail-appendage. Wings hyaline with a black base, margins, middle and apical spots. Expanse of wings: 32 to 38 mm. Venezuela.
- grandis.* **T. grandis** Kaye is a very large species with an expanse of wings of 50 mm. Body black; the forehead, a dorsal spot on the 1st abdominal ring and minute lateral spots on the others are metallic green; on the 3rd and 5th segments sublateral white spots. Forewings ochreous-yellow hyaline with very narrow black margins; hindwings white hyaline with a broad black proximal margin and apex. South Brazil (Santos).
- melanosoma.* **T. melanosoma** Hmps. (18 e) is easily recognizable by the large, black apical spot of the forewing. The body is jet-black, above with indistinct deep-blue spots on the forehead, vertex, collar, metathorax and base of abdomen; the abdomen exhibits on the strangulated segment sublateral white stripes. Brazil (Sa. Catharina).
- fumida.* **T. fumida** Kaye is smaller than *esmeralda* (18 e) and has an entirely black abdomen without green spots, only the head and thorax exhibit single metallic green, small spots. The forewings are smoky-brownish hyaline, the hindwings bluish hyaline, both with a somewhat broader black margin than in *esmeralda*. Expanse of wings: 34 mm. Trinidad.
- esmeralda.* **T. esmeralda** Wkr. (18 e) differs from *cerberus* by the hyaline forewings not being yellow and their narrower margins. The forewings exhibit an orange-yellow spot at the base. The ventral side exhibits behind the white basal spot only a pair of white sublateral spots. Honduras, Guatemala, Venezuela, Brazil (Pará, Rio de Janeiro). — In Colombia flies a form with entirely white, sublateral macular rows: **completa** form. nov., which is before us from the Rio Dagua (A. H. FASSL).
- pusilla.* **T. pusilla** Rothsch. Head, collar, chest, and a spot on the blackish-brown thorax are steel-blue. Palpi white. Abdomen greenish steel-blue; the strangulated ring shows lateral white spots; tail-appendage as long as the abdomen. Forewings yellow hyaline, narrowly bordered with black. Hindwings whitish hyaline with a black apical spot. Expanse of wings: 26 mm. Peru.
- latifascia.* **T. latifascia** Wkr. (18 e) has a black body with a deep metallic blue lustre; the strangulated 2nd abdominal segment exhibits on each side a large white spot. In the nomenclatural type, the discoidal spot of the forewing is broad. This type flies in Brazil (Pará, Rio de Janeiro). — In **ismene** Möschl. (= ribbei Druce) the discoidal spot is very narrow. This form flies more in Central America, Panama, Colombia, Surinam, but it is also stated from Bolivia.
- dixanthia.* **T. dixanthia** Hmps. (18 e) is presumably much rather to be considered a form of *latifascia*, for the only difference is the orange-yellow colour of the lateral spot of the 3rd segment; both vary extremely in the width of the black margins and discoidal spots, and among a great number of ♂♂ of both forms lying before me, from the same habitat, the one half has a tail-appendage, the other half not, which, therefore, is presumably no distinguishing mark, for other differences are not to be discovered. Likewise from Brazil (Minas Geraes, Santos).
- coarctata.* **T. coarctata** Drury (18 e). Body black with minute, metallic bluish-green spots on the forehead, vertex, collar, thorax and abdomen, the 2nd segment of which exhibits a white spot underneath; the 3rd segment shows 2 white sublateral spots. Wings faintly yellowish hyaline, with black margins. From Venezuela and Brazil (Pará, Pernambuco, Rio de Janeiro, Santos).
- druryi.* **T. druryi** Hbn. (= *coarctata* Cr.) (18 f) has a black body being spotted metallic bluish-green on the forehead, collar, shoulder-covers and thorax; the forehips, the ventral side of the 2nd abdominal ring, and some spots on the 3rd are white. Above, the abdomen exhibits on the first 3 rings metallic green transverse bands, on the following rings similar dorsal and lateral spots. The yellowish hyaline forewings have an orange-yellow costal and proximal margin, and a narrow black distal margin. In the ♂ the black discoidal spot is broader, and the hips are black. Widely distributed from Mexico to British Guiana.
- cyanea.* **T. cyanea** Schaus (18 e) approximates *druryi* and differs by its quite black, not bluish-green spotted abdomen which is orange on the lateral tubercles at the base, and sublaterally striped white on the 3rd and 4th segments. Head, collar and legs are spotted metallic blue. Costal and proximal margins of the hyaline wings are orange. Rio de Janeiro.

T. mathina Druce (18 f) is distinguished by entirely orange-yellow antennae; the body is black, *mathina*, with orange spots on the head and thorax; the black abdomen exhibits yellow bands above only on the 3 first segments; underneath, the 2nd segment is white, the third shows sublateral white spots. The wings are transparent orange-yellow with narrow black distal margins, on the hindwings the lower end of the discocellular is connected with the marginal band by a small black spot. The forehips are white in the ♂. French Guiana.

T. aurifera Btlr. (= melas var. Wkr.) (18 f) is a large, imposing animal with a black body; head and *aurifera*, thorax with orange-yellow spots, palpi and legs quite orange, the latter except the black tarsi. The forehips in the ♂ white. The first 4 abdominal rings exhibit orange-yellow transverse bands, the 2 following ones yellow dorsal spots and subdorsal blue spots; the second ventral segment is quite white, the 3rd exhibits 2 white spots. The yellowish hyaline wings are orange at the costal and proximal margins, the appendage to the proximal margin of the hindwing is orange and black-haired. The antennae are quite black. Venezuela; French Guiana; Amazon (Pará).

T. fasciata Rothsch. (18 f) is somewhat smaller than the preceding and distinguished by the quite *fasciata*, orange-yellow, black-curved abdomen; only the two last rings are black with white, large, round spots of a blue iridescence. All the rest is like in *aurifera*, also the antennae are black. Peru, Chanchamayo.

T. frigida Burm. is black on the head and thorax, with white hair; base of antennae yellowish. The first *frigida*, 3 abdominal rings black, the others yellow-haired; above there are triangular white spots, which are bordered with black on the yellow segments. Venter white. Wings hyaline with black veins and margins being strewn with white scales like the hyaline parts, the most densely at the base and proximal margin. Expanse of wings: 30 mm. Argentina (Buenos Ayres).

64a. Genus: **Corematura** Btlr.

Like the preceding genus, but the antennae are not thickened; the abdomen is strangulated at the 2nd and 3rd segments and exhibits a very long anal hair-tuft. On the forewings both the lower radial veins rise from the cell-angle, in *Trichura* the middle one rises separated from the lower one above it.

C. aliaria Druce (18 f) has a considerably more strangulated abdomen than the following. Head and *aliaria*, collar are orange-brown, the rest of the body is greenish bluish-black. The anterior side of the palpi, the sides of the forehead, and the hips are white; the 2 first abdominal segments are white beneath, the 3rd exhibits a white spot, being forked towards the anal end. French Guiana to Brazil.

C. chrysogastra Perty (= postflava Guér., abdominalis Wkr.) (18 g) is an easily recognizable species: *chrysogastra*, the head is black, with yellow spots and stripes on the thorax; the abdomen shows yellow, triangular dorsal spots, broad, carmine lateral stripes, and an orange-yellow venter; the long anal tuft is black. Ecuador, Peru, Bolivia, Amazon.

64. Genus: **Pezaptera** Btlr.

From the preceding genus it differs by the upper median vein and the two lower radial veins rising jointly from one place. The strangulation on the abdomen is only trifling, and instead of the long anal tuft there are only short hair-tufts at the end and sides of the last ring.

P. sordida Wkr. (= divisa Wkr.) (18 g). Blackish-brown, antennal tips white. The abdomen exhibits *sordida*, on the 2 first rings lateral white spots and a ventral spot on the first ring; the anal tufts are carmine. Wings hyaline, with black veins, margins, discoidal and apical spots. Expanse of wings: 24 mm. Amazon.

65. Genus: **Homoneuronia** Dyar.

Siphon well developed; the erect palpi extend beyond the vertex. Antennae doubly combed in the ♂, the shaft thickened in the middle. Abdomen strangulated at the base. Spurs of tibiae short. On the forewings the upper median vein rises far from the lower cell-angle; the lowest radial vein is absent. On the hindwings both the median veins rise from the same place and approach each other again towards the margin; both the lower radial veins come from the lower cell-angle, the subcostal and the upper radial vein from the upper one.

H. modesta Schaus. Body and legs are blackish-blue, the antennae black. Chest, forehips, and the *modesta*, strangulated abdominal ring, laterally and beneath, are white. Wings hyaline with black veins and margins; the hindwings are opalescent whitish, margin and apex are broader black. Expanse of wings: 27 mm. French Guiana.

66. Genus: **Aethria** Hbn.

It contains species mostly copying the genus *Dinia*. The black abdomen, often with a blue lustre and white spots, shows a large red anal tuft, but the last segments are laterally not provided with hair-tufts. The extremely extensive cell of the hindwing, the transverse vein of which disappears in the marginal band, makes it approach the preceding genera; all the veins rise separately. The abdominal strangulation is slight.

sarcosoma.

A. sarcosoma Btlr. (= *laudamia* Druce) (18 g) differs from all the species by the abdomen being entirely carmine except the 1st ring, with minute white dorsal spots and black segmental lines. Anal tuft in the middle black; the 3 first segments and the last one are white beneath. Spots on the forehead, collar, shoulders, shoulder-covers, thorax and legs are white; collar with opalescent blue spots. Wings hyaline with black veins, broad margins and discoidal spots. Expanse of wings: 32 mm. Colombia.

sanctula.

A. sanctula Dogn. (18 g) has a quite black body with a blue lustre above. The last abdominal rings are scarlet above, the anal tuft ochreous-yellow. Wings hyaline, with black margins and veins, and very large, square discal spots. Expanse of wings: 35 mm. Brazil (Santos).

*andro-
macha.*

A. andromacha F. (= *sanguiflua* Hbn.-G. nec Wkr., *finalis* Wkr., *pennata* Möschl.) (18 g, as *andro-macha*) differs from the allied species by the orange colour of the two last abdominal segments. Above, the abdomen is unicolorously black, without any blue spots. The underside of the palpi, spots on the shoulders, forehips, as well as the ventral side of the two first abdominal rings are white in the ♂. — The form **rubra** form. nov. (= ab. 1. *Hmps.*) (18 g) has the two last abdominal rings carmine; it lies before me from Bolivia; the species is besides found in Venezuela, Surinam and Pará.

carnicauda.

A. carnicauda Btlr. (= *sanguiflua* Wkr.) (18 h) has a black body with a metallic blue small spot, the anal tuft is of a bright carmine; distinguishable from *aner* by its entirely black underside, palpi and shoulders. — From Trinidad, Venezuela, Brazil (Pará, Sa. Catharina, Santos).

innotata.

A. innotata Schaus, which remained unknown to me, according to the short, insufficient description, seems to belong here. Body black with a carmine anal tuft. Wings hyaline, with black veins and black margins; the distal margin broader black, particularly at the apex and proximal angle. Transverse vein broadly black. Hindwing very broadly bordered with black. Expanse of wings: 38 mm. Brazil (Petropolis).

analís.

A. analis Schaus, described from Peru, is likewise unknown to me in nature; antennae black, combed and thickly scaled above the middle third. Body black, with blue scales on the collar, shoulder-covers and femora. Abdomen black, the 3 last rings orange-red. Wings hyaline with black veins and margins. The distal margin of the forewings inside dentate; transverse vein broadly black; at the base of the proximal margin some violet hairs. Hindwings with a broad, black distal margin. Expanse of wings: 29 mm.

aner.

A. aner *Hmps.* (*carnicauda* *Hmps.*) (18 h) is a smaller species, which is well characterized by the extensive white colouring of the underside: palpi, sides of forehead, basal joint of the antennae, fore- and hindhips, the 3 first abdominal segments and sublateral spots on the others, as well as a ventral spot at the anal tuft are white, as well as spots on the shoulders; on the upperside the abdomen shows metallic blue dorsal spots, the anal tuft is carmine; in **auriflua** form. nov. it turns ochreous-yellow. — Described from Venezuela, the yellow form is before me from French Guiana.

fulvicauda.

A. fulvicauda Btlr. (18 g) differs from the similar species by the black, posteriorly blue-banded abdomen, the extreme anal tuft of which is yellow; the 3 first rings and the last ones are white beneath; fore- and hindhips white like the anterior side of the palpi and of the collar. Expanse of wings: 28 mm. Brazil (Sao Paulo).

stipata.

A. stipata Wkr. (18 h) differs from the species known by its ochreous-yellow underside with earmine lateral spots and black middle spots on the abdomen; the blackish-brown, blue-lustrous abdomen exhibits a series of dorsal yellowish spots. Anterior body blackish-brown with white dots. Wings hyaline with black margins and veins, a white dot at the base of the costa on the forewing, the proximal margin being striped yellow. Expanse of wings: 34 mm. Amazon (Pará).

eburneifera.

A. eburneifera Fldr. (18 h). The body is black; white are: the anterior side of the palpi, the basal joint of the antennae, throat, hips and stripes at the front femora. The collar, shoulder-covers and metathorax are spotted blue, the 3 first abdominal rings above blue; the first 4 rings exhibit dorsal double rows of dots and lateral carmine spots, the other rings on the dorsum and sides one white row of dots each. Underneath, from the 2nd to 4th rings there are triangular white spots, on each of the next two segments 2 spots. Wings hyaline with black veins and margins, the base being black with a blue spot. Expanse of wings: 38 mm. Amazon.

A. gracilis Möschl. (18 h). Body blackish-brown, with a whitish-blue reflection, and a narrow, white *gracilis*. dorsal stripe on the abdomen; the 2 last rings are laterally carmine, so is the anal tuft, which is intermixed with black in the ♂; in the ♀ the last ring and the anal tuft are quite red. Wings opalescent hyaline with black veins and margins, and a black discoidal spot in the ♂. Expanse of wings: 34 mm. Surinam; Rio de Janeiro.

A. dorsilineata Hmps. (18 h). One of the smallest species particularly distinguished by two fine, white, *dorsilineata*. dorsal, longitudinal lines running across the thorax and abdomen. Collar and shoulder-covers are bordered with white; the whole underside of the abdomen is carmine, above only the last segments, as well as the sides of the anal tuft, which is black in the middle. The wings are milky-white diaphanous with narrow black margins. Hitherto known only from Jamaica.

A. paulista spec. nov. (18 h) is one of the smaller species with a black body; anterior side of the palpi *paulista*. and forehead are white; vertex, collar and metathorax of a metallic bluish green lustre. The abdomen exhibits above triangular, white dorsal spots, being surrounded by opalescent blue, furthermore white lateral spots, and the ventral segments are posteriorly margined by white. The last segments are laterally red-haired, the anal tuft is red with a black middle. The hyaline forewings with narrow black margins have a large, black discoidal spot; the hindwings are very broadly margined by black. One ♂ from Sao Paulo from BANG-HAAS.

A. lepida spec. nov. (18 i) ought to form a section of its own, owing to the upper radial rising far below *lepida*. the upper cell-angle. It is allied to the subspecies *manca* of the following species, but it is still smaller, with narrower wings, without a discoidal spot of the forewing, with but narrow black distal margins. The ventral side of the abdomen is curled white; above there are white dorsal spots surrounded by a faint blue; the white lateral spots are insignificant and coalesce with the white ventral bands. The anal tuft is black in the middle, laterally red. One ♂ from St. Laurent du Maroni (French Guiana); type in the Coll. DRAUDT.

A. leucaspis Cr. (18 i) greatly resembles *daltha* from which, however, it is immediately distinguishable *leucaspis*. by the absence of the subapical hyaline spot of the hindwing. The under surface of the abdomen is black with white sublateral spots. The anal tuft being generally carmine may also be yellow: **flava** form. nov. (18 i). Not *flava*. rare and distributed from Venezuela through Guiana as far as Brazil. — In Bolivia there flies a subrace: **manca** *manca*. subsp. nov. being considerably smaller. Its forehead and anterior half of the collar is white, the abdominal spots are also of a plain white, not bordered with blue. The discoidal spot of the forewing and the border of the hindwing are broader.

A. daltha Druce (18 i) is well characterized by its size and the hyaline subapical spot in the black *daltha*. marginal band of the hindwing. It differs from the strikingly similar *eliza* by the two lower radials rising closely together and by the antennae not being thickened in the middle, and particularly by the entirely white ventral side of the abdomen, only the last segments being black, with white spots; all the hips are entirely white, too, and the legs striped white. Amazon (Pará); also from French Guiana (St. Laurent du Maroni).

A. eliza Klages (18 i) is one of the largest and most beautiful species, resembling above *daltha* so very *eliza*. much that one is obliged to look very closely. Beside the differences of the neurulation mentioned there and the antennae being thickened in the middle, it may be recognized by the black underside of the abdomen exhibiting lateral and sublateral rows of white spots. Above the first segments are almost entirely metallic blue with white dorsal spots, beginning from the 4th ring, the white dorsal spots are placed in blue spots growing smaller towards the anal end. — The species having been described from Venezuela is before me also from Bolivia (Rio Songo); the latter form: **tenuistriga** form. nov. (18 k) has much finer black margins, the discal spot of the *tenuistriga*. hindwing is not coherent with the marginal band.

A. ocina Druce (18 k) differs from the similar species by the black discal spot of the hindwing being *ocina*. separated from the marginal band. Metathorax and abdomen at the base metallic blue. The abdomen exhibits dorsal and lateral rows of white spots, the ventral side is quite white. Anal tuft carmine and black. Expanse of wings: 44 mm. Bolivia.

A. langleyi Klages. The body is black, the forehead laterally white. Spots on the collar and shoulders, *langleyi*. shoulder-covers and thorax are of a golden green; forehips with silvery white spots. Abdomen above of a metallic blue lustre, with dorsal and lateral rows of golden green, white-pupilled spots; anal tuft and the last segment laterally carmine; on the venter there are 2 rows of white spots. Wings hyaline with black veins and margins; base of the forewing black with a golden green spot. Expanse of wings: 30 mm. Venezuela.

A. platyzona Fldr. (18 k) is quite unlike the other *Aethria*-species known and entirely resembles a *platyzona*. *Cosmosoma* from the *stibostictum*-group: head and thorax are black, on the forehead and vertex some blue spots, the abdomen being orange-yellow, except the first segment and the 3 last ones being black. The hyaline wings show broad black margins and discoidal spot. Colombia.

rubipectus.

A. rubipectus *Schaus* (18 k) is likewise dissimilar to the other species, above black, on the thorax and abdomen a blue lustre; anterior side of the palpi, forehead, neck and borders of the shoulder-covers are white; chest and hips carmine. The hyaline wings exhibit narrow black margins. Hayti.

67. Genus: **Paraethria** *Hmps.*

The abdomen is not strangulated, does not exhibit any lateral hair-tufts at the end, but it is above roughly haired at the base. On the forewings the median veins are on a common petiole, the middle radial vein rises above the lower cell-angle. On the hindwing with a long cell the subcostal and 1st radial vein rise petioled, all the others separately.

angustipennis.

P. angustipennis *Rothsch.* (19 a) and the following species have somewhat stunted hindwings. The body is black, the palpi are entirely white; the abdomen shows at the sides of the 3rd segment a small whitish spot. From the Amazon.

mapiria.

P. mapiria *spec. nov.* (18 k) is perhaps only a form of the preceding, at any rate it is very near to it. The body is above metallic bluishgreen, also the legs, otherwise below black. The palpi are black, only at the anterior side white like the forehead. The abdomen exhibits above on the 3 first rings a white longitudinal stripe, at the sides of the same segments a very large, yellowish-white spot being connected across the ventral side with that of the other side. Described according to a female from Bolivia (Mapiri); from BANG-HAAS.

triseriata.

A. triseriata *H.-Schöff.* (18 k) is black with white dots on the thorax and abdomen. Characteristic are the hindwings being black with a basal hyaline spot below the cell; the forewings are hyaline with broad black margins; the middle radial vein is more intensely black than the others. Found from Brazil as far as Argentina, in day-time on compositae.

flavosignata.

P. flavosignata *Rothsch.* (19 a) differs from *triseriata* by the orange-banded segments 2 to 6 of the abdomen and by the thorax being spotted and striped orange-yellow; head, palpi, and forehips are orange, the legs brown, the antennae black. The two last abdominal rings are spotted scarlet. On the yellowish hyaline wings the black margins, particularly at the proximal margin, profusely powdered with brownish scales. Bolivia.

68. Genus: **Aethriopsis** *Btlr.*

Veins of hindwings like in the preceding genus. On the forewings the median veins and the lower radial vein rise widely separated, the upper radial rises below the upper cell-angle. The palpi are longer than in *Paraethria*.

barbata.

A. barbata *Schrottky.* Body black; forehead, posterior margins of the eyes, spots on the collar and stripes on the shoulder-covers white. Chest anteriorly with rosy red hair, laterally spotted white; anterior and posterior hips, as well as the apices of the posterior femora white. Abdomen with lateral white spots, underneath in the middle white. Wings hyaline with black veins and discal spot, beginning from which the costal margin, as well as the distal and proximal margin are broadly bordered with black. Hindwings opaline-white, at the costal margin yellowish, below it black. Expanse of wings: 28 mm. Paraguay.

69. Genus: **Argyroeides** *Btlr.*

Easily recognizable by the long, slender abdomen, the 2nd segment being strangulated, and with hair-tufts at the end. The entirely hyaline forewings are broad, the hindwings narrow, the proximal margin is formed by a small lobe covered with hair. The upper median vein of the forewing rises below the cell-angle, the 1st subcostal vein from the cell.

strigula.

A. strigula *Druce* (19 a) has the shoulder-covers and abdominal rings bordered with orange-red; a spot on the metathorax and the strangulated 2nd segment are yellowish-white; forehead and vertex blue; the second joints of the palpi, bases of antennae, spots on shoulders and hips are white; venter banded yellowish-white. The wings are faintly yellowish hyaline with narrow black margins. Brazil (São Paulo).

flavicornis.

A. flavicornis *Rothsch.* (19 a) is one of the larger species, recognizable by the orange-yellow antennae. Body black; palpi and 2 spots between the eyes golden yellow, the proximal margin of the shoulder-covers orange-haired; the abdomen is suffused with blue and exhibits on each side of the first ring a yellow spot; forehips white, middle and posterior hips cream-coloured, ends of tibiae orange-yellow, the legs otherwise brown. The wings are yellowish hyaline, veins, costal and proximal margins orange, distal margins narrowly black. Amazon (Teffé).

A. menephron *Druce* (19 a). Head yellow, with black spots on the forehead and vertex, collar and shoulder-covers black, bordered with yellow; thorax black with a yellow middle line and posteriorly a yellow transverse band. Chest and legs yellow. Abdomen black, on the 1st and the 4 last rings yellow bands; the strangulated segment laterally and beneath yellow. Wings hyaline with yellow and black veins and margins. Expanse of wings: 24 mm. Panama. *menephron*.

A. flavicincta *Druce*. Body black, collar bordered with yellowish-brown; the abdomen is above and beneath curled yellow. Wings brownish hyaline with black veins and margins. Expanse of wings: 26 mm. Venezuela. *flavicincta*.

A. vespina *Schaus* (= *lydia* *Druce*) (19 a) most strikingly copies certain *Pseudospheex* and *Sphecosoma*-species: the body is above black, collar and thorax striped yellow, the abdomen with yellow bands. The antennae are black; the underside and legs reddish-yellow, forehips light yellow. The wings are yellowish hyaline, in the ♀ dusted darker; in the latter the tips of the antennae are yellow. Paraná, Rio Grande do Sul; Paraguay, in day-time on the blossoms of Senecio. *vespina*.

A. fuscipes *Rothsch.* has an entirely black body with dark-brown legs; the strangulated abdominal segment is yellow-brownish. Wings yellow hyaline, the forewings a little darker with brown veins, the hindwings with black veins, distal and proximal margin. Minas Geraes. *fuscipes*.

A. spectrum *Schaus*. Body above black; at the base of the abdomen there is a yellow-reddish transverse streak. The abdomen exhibits on the 3 first rings a white lateral stripe, the venter a white middle stripe. Thorax below striped white. Legs light brown. Wings hyaline. Veins and margins reddish-brown, the distal margin in the apical half darker. Expanse of wings: 28 mm. Costa Rica. *spectrum*.

A. ortona *Druce* (19 b) has a black body with a blue-lustre on the abdomen; palpi and femora striped white, shoulders and hips spotted white; the neck is carmine, the venter white. The wings are hyaline with black margins, a broad, blackish-brown proximal margin, discal and apical spots. Ecuador. *ortona*.

A. rubricauda *Dogn.* ♂ (= *quindiensis* *Dogn.* ♀) (19 a, b) is on the body chestnut-brown, on the sides of the abdomen orange. Wings hyaline with a broad, brown border, the costal base yellowish, distal margin on both the upper radial veins proximally expanded; veins and a large discal spot brown. Hindwings at the proximal margins with blackish hair. In the ♂ the orange lateral stripes only begin from the 3rd ring and are above united on the last segments. Colombia (Quindiu Pass, 3800 m, Monte Socorro); the discal spot is in the ♂ considerably narrower. Legs and chest in the ♂ whitish, in the ♀ more olive-brown like the venter which is white in the ♂. According to the couple before me from the Coll. SEITZ, I unhesitatingly combine *quindiensis* as the ♀ with *rubricauda* as the ♂. *rubricauda*.

A. notha *Schaus*. Anterior body and 1st abdominal ring black. Forehead white. Abdomen above dark brownish green, laterally rosy. The strangulated segment bare; underneath the 2 first rings white, the others rosy banded. Chest and legs black, femora white, anterior femora striped red. Forewings hyaline with fine black veins and margins; at the base and at the proximal angle one small red spot each. Hindwing with a broadly black apex and proximal margin. Expanse of wings: 25 mm. Costa Rica. *notha*.

A. auranticincta *Klages*. The head and the whole underside is orange, as well as the bases of the antennae; antennae, collar and thorax above black; borders of the collar and of the shoulder-covers, as well as a spot on the metathorax orange. The strangulated abdominal segments are above unscaled, brownish-yellow, the other rings posteriorly with orange bands, the anal tuft carmine. Wings yellow hyaline with black veins strewn with yellow, and narrow black margins; costa and a basal spot on the forewing, often exhibiting a red dot, as well as the proximal margin of the hindwing orange. Expanse of wings: 24 mm. Venezuela. *auranticincta*.

A. boliviana *Druce* (19 b) differs from the preceding by its black head and white chest and hips; the strangulated rings are scaled and orange. Expanse of wings: 28 mm. Bolivia. *boliviana*.

A. braco *H.-Schäff.* (19 b). The body is black, on the head, collar, metathorax and 2nd abdominal segment white spots. The shoulder-covers are striped carmine, the lateral stripes on the posterior abdominal rings, and the anal tuft being red, too. From Venezuela, São Paulo, Paraguay, very common almost the whole year round, and in heaps together with other small species particularly on the blossoms of Senecio brasiliensis. *braco*.

A. ophion *Wkr.* (19 b) is much larger than *braco* from which it differs besides by the shoulder-covers being quite black. The black body has a slight blue reflection, and the head is all black. The strangulated abdominal ring is only laterally yellowish-white, above black. Honduras, Venezuela, Brazil (Sa. Catharina). *ophion*.

A. tricolor *Pack.* Body blackish-brown; between the eyes and antennae yellow lines, and a triangular yellow spot on the hindhead; palpi yellow, outside striped black; collar and shoulder-covers spotted yellow. The 3rd to 5th abdominal rings scarlet; the first 5 rings exhibit above a yellow macular stripe. Chest, legs and the basal two thirds of the venter are ochreous-yellow. Wings hyaline with fine black veins and margins, and apical spot. Inner-marginal appendage of the hindwing brown with a light end. Expanse of wings: 36 mm. Amazon. *tricolor*.

- sanguinea*. **A. sanguinea** Schaus (19 b). The yellow-white collar, entirely black head and thorax separate this species from the similar ones; the first abdominal ring is above yellowish-white, the 5 last ones with carmine bands; underneath the 2nd ring exhibits a white spot. The hyaline forewings exhibit a relatively large, black, apical spot. Brazil; it is also before me from Paraguay (Puerto Bertoni).
- affinis*. **A. affinis** Rothsch. (19 b). By the red-striped shouldercovers and the entirely black head and collar, the species is at once discernible from the two preceding, similar species. The base of the hips and a spot below the shoulder are white; the first abdominal ring is yellowish-grey, the 5 last ones above with red bands. The wings are yellowish hyaline with but very narrow black borders. Brazil (Minas-Geraes).
- ceres*. **A. ceres** Druce (19 c). The lustrous metallic blue abdomen spotted white above makes the species easily recognizable; the rest of the body is black; anterior side of the palpi, sides of the forehead, neck, chest and hips are spotted white. Underneath the two first abdominal rings are white, two middle segments and the last ones spotted white. The wings are comparatively broadly bordered with black. Venezuela and British Guiana.
- placida*. **A. placida** Druce (19 c) has a black body with metallic blue spots; the strangulated 2nd abdominal ring is yellowish-white, on the ventral side broader than above. Ecuador.
- minuta*. **A. minuta** Druce (19 c). Body black, with a faint blue lustre; the anterior side of the palpi, sides of the forehead, bases of antennae, and spots on the chest and hips are white; the strangulated abdominal ring is yellowish; on the underside the 4th and the last segments exhibit white transverse bands. The hyaline forewings are yellowish in the disc. Honduras.
- eurypon*. **A. eurypon** Druce (19 c) has a black body; orange are: a band behind the eyes, and the anal tuft; the anterior side of the palpi, forehead, shoulders, sides of the thorax, and hips are spotted white; the first 4 abdominal rings are laterally yellowish-white; underneath the 3rd and 4th rings show a white band. The forewings exhibit an orange-yellow spot at the base of the costal margin. Guatemala and Panama.
- augiades*. **A. augiades** Druce (19 c) is easily recognizable by the deep carmine head and thorax; the other part of the body is bluish-black, in some places spotted white. From Ecuador, known also from Colombia and Bolivia.
- variegata*. **A. variegata** Kaye has a black body. Shoulder-covers striped carmine. The 2nd and 3rd, as well as the 3 last abdominal rings exhibit dorsal, double, blue dots, the 5th segment a yellow band. Wings hyaline, finely bordered with brown, and with a brown discal streak. Tibiae carmine. Expanse of wings: 32 mm. Paraná, in April.
- laurion*. **A. laurion** Druce (19 c) has a black body; the anterior side of the palpi, throat and hips are white; the second and third abdominal rings are laterally and beneath yellowish, the anal tuft, too. A characteristic mark of the species is the black distal margin projecting in the shape of a spot between the 2 upper radial veins and the lowest subcostal vein, also on the hindwings. The forewings exhibit a small red basal spot, red scales being also noticeable at the costal margin between the middle and apex. From Panama.
- flavipes*. **A. flavipes** Hmps. (19 d) is recognizable by the orange-yellow legs; the body is brownish-black, the strangulated abdominal rings are laterally and beneath yellowish. Brazil (Castro in Paraná).
- magon*. **A. magon** Schaus (= *gyas* Druce) (19 d) differs from *flavipes* by the black legs with white hips; the strangulated abdominal ring is above and beneath yellowish. The yellowish hyaline wings have somewhat broader black margins. Brazil (Sa. Catharina).
- hadassa*. **A. hadassa** Druce (19 c) is the most imposing species with a black body; chest, hips, and abdomen above and at the sides spotted metallic blue; the venter exhibits on the two first segments white discal spots, on the others white double spots, of which the first and fourth are the largest. The yellowish hyaline wings with orange-yellow costal and proximal margins exhibit narrow black distal margins. Ecuador.
- suapurensis*. **A. suapurensis** Klages differs from all the other species by the posterior tibiae exhibiting rough hairy scales; body blackish-brown; anterior body in some parts with yellowish or grey hair; forehips and spots on the middle and posterior hips whitish. On the abdomen the strangulated segments are bare, brownish-yellow; the next segments bordered with yellow. Wings yellow hyaline, veins and margins finely blackish-brown, in some places strewn yellowish; inner-marginal appendage on the hindwing black-haired. Expanse of wings: 23 to 26 mm. Venezuela.

70. Genus: **Didasys** Grote.

Siphon well developed. Palpi long, erect. Antennae in both sexes doubly combed, in the ♂ long, in the ♀ short. The abdomen exhibits on the last rings lateral hair-tufts; in the ♂ the valves exhibit very long hair-tufts. The neuration as in *Argyrooides*, but the middle radial rises on the forewing above the lower cell-angle.

D. belae Grote (19 d). Head, collar, and abdomen scarlet; thorax and legs striped black and white. *belae*. The abdomen exhibits dorsally and on the 1st ring laterally small black spots, the 2 valval tufts are black. Venter whitish, with black bands. Wings hyaline with black veins and margins. The base of the forewing, a discal spot bordered with black, and an antemarginal series of spots in the broadly black distal margin are scarlet. In the ♀ the abdominal spots are larger and the anal apex is black. Expanse of wings: 28—34 mm. Florida.

71. Genus: **Burtia** Grote.

The terminal joint of the erect palpi is porrect. The abdomen exhibits on the first segment lateral tubercles, on the last lateral hair-tufts, and in the ♂ very long and hairy elapsing-organs. On the forewings the lower radial veins rise separately, all the subcostal veins on a joint pedicle; on the hindwings the upper median vein rises before the lower cell-angle which sends forth the lower radial veins; the subcostal vein far before the upper cell-angle.

B. cruenta H.-Schäff. (19 d). Vertex, collar, and abdomen carmine; palpi and forehead black and *cruenta*. white. Thorax brown, the shoulder-covers bordered with white; chest and legs striped red and white. Venter with a white median stripe, anal tuft partly black. Wings hyaline with black veins, margins, and apical spot; at the costal margin a red stripe. Expanse of wings: 22 mm. Cuba.

B. rubella Grote (= *cruenta* H.-Schäff. pr. p.) (19 d) differs from the preceding by its entirely black *rubella*. anal tuft, and above all by the apical spot of the forewing being filled up with carmine. Likewise found only in Cuba.

72. Genus: **Hypocladia** Hmps.

It differs from the allied genera, above all by the long and narrow shape of the wings, by which, together with the deviating marking, there appear certain resemblances to *Chrostosoma*. Veins of the forewings as in *Didasys*; on the hindwings the upper median vein and the lower radial vein come from the same place of the lower cell-angle, the subcostal and the 1st radial vein in the same way from the upper cell-angle.

H. militaris Btlr. (19 d). Body brown; spots on the vertex, collar and metathorax, as well as lateral *militaris*. stripes on the abdomen, being broken up into spots, are carmine. Forehips and transverse bands on the ventral side white. Forewings brown with whitish stripes in and below the cell, as well as a bent transverse row behind the cell. Forewings blackish-brown with diaphanous stripes in, below and behind the cell. Expanse of wings: 28 mm. Amazon.

H. parvipuncta Hmps. differs from the preceding by its entirely blackish-brown body exhibiting *parvipuncta*. carmine spots on the shoulders and 1st abdominal ring. Venter and base of palpi spotted white. Wings as in *militaris*. Expanse of wings: 30 mm. British Guiana.

H. restricta Hmps. likewise resembles the preceding. Body blackish-brown, tips of antennae white; *restricta*. vertex and shoulders with carmine spots, as well as the sides of the 2 first abdominal rings, while the rest of the abdomen is above black, on the ventral side white, forehips and stripes on the legs white, too. Forewings blackish-brown with a purple lustre, with similar hyaline spots as the preceding; the postdiscal ones between the upper median and middle radial vein extend far towards the margin. Hindwings black with hyaline spots in, below and behind the cell. Expanse of wings: 30 mm. Panama.

H. albipuncta Druce. Body brown. Neck and broad lateral stripes on the abdomen red. Forewings *albipuncta*. brown, behind the cell with 3 small white spots, at the base of the proximal margin a white blurred spot. Hindwings white, bordered with brown. Expanse of wings: 40 mm. South East Peru.

H. elongata Druce. Anterior body brown, neck and abdominal base yellow. Abdomen above brown, *elongata*. with subdorsal darker spots, laterally and beneath red. Forewings dark-brown with lighter veins; behind the cell there is a broad, brownish-white oblique spot extending from the costal to the distal margin. At the base of the cell a greyish-white stripe, in the middle 2 dots. Hindwings diaphanous white, bordered with brown. Expanse of wings: 46 mm. Venezuela.

H. calita Dogn. Head blackish; base of palpi and 1st joint of antennae rosy, vertex yellow. Collar *calita*. and shoulder-covers white with black spots. Abdomen above yellow, from the 3rd to 7th rings above spotted black, on the following rings banded black; at the sides a row of black dots; venter, hips, inner side of femora, ankles and tarsi rosy, legs otherwise grey. Forewings of a pure white, on the veins and margins grey with black spots between the veins in transverse rows near the base, before the middle, at the cell-end, creating the impression of a large, oval, postdiscal transverse spot, behind it a short row from the costa to the middle radial vein, as well as a row before the margin. Hindwings white, bordered with brown, at the proximal margin yellowish. Expanse of wings: 40 mm. Colombia.

73. Genus: **Hyalomis** *Hmps.*

Small species with broad, hyaline forewings exhibiting on the under surface at the proximal margin a hairy cover. The upper median vein and the lower radial veins all rise far separated from the lower cell-angle. The hindwings are very narrow and short, pointed, with a long, though extremely narrow cell, so that the transverse vein is very short. The upper median vein and lower radial vein are absent, the subcostal and 1st radial vein are long-petioled. The abdomen is not noticeably strangulated.

espia. **H. espia** *Dogn.* Body above black; 4 abdominal rings yellow, the 3 first ones above interrupted by black. Underside yellow, legs yellow and black. Wings hyaline with fine black distal margins, apical spots and veins; costal and proximal margins yellow. Expanse of wings: 23 mm. Ecuador (Loja).

thyria. **H. thyria** *Druce* (19 d). This small, neat species has a bluish-black body, being white beneath; anteriorly below the shoulders there is on each side a red spot. The very faintly yellowish, hyaline wings exhibit very narrow black margins. The costal margin of the hindwing is white-haired. From Ecuador and Bolivia.

hypochryseis. **H. hypochryseis** *Hmps.* (19 d). Body black with carmine spots on the anterior chest as in the preceding, but the abdomen shows orange lateral spots and an orange underside; orange are, furthermore, the anterior side of the palpi, forehead, throat, and spots on the collar, the borders of the shoulder-covers, and the feet. The narrow hindwings have above a white, beneath an orange-yellow costal margin and orange-yellow fringes. From Brazil.

platyleuca. **H. platyleuca** *Wkr.* (19 d). Body above black, beneath white, forehead margined with grey; tips of antennae white; shoulder-covers with a fine yellowish border. Wings hyaline with fine black veins and margins; costa of the hindwing white with a black stripe below it. Expanse of wings: 24 mm. Venezuela.

74. Genus: **Diptilum** *Prittw.*

This peculiar genus contains species distinguished by a great reduction of the hindwings, in some they even almost disappear entirely. On the very broad forewings the upper median vein and the lower radial veins rise separately; the proximal margin is in several species beneath covered with hair. The hindwings, in case they are developed, are narrow, pointed, and the lower radial is absent; the 1st median and 2nd radial rise separately. In case they are stunted, they disappear below the forewings, only the separated inner-marginal part hanging down as a hairy, small lobe.

Sect. I. Hindwings greatly stunted.

telamonaphorum. **D. telamonaphorum** *Prittw.* (26 l). Body blackish-brown. Throat carmine; hips white; tarsi and underside of the posterior tibiae orange-red. The abdomen exhibits above on the 2nd to 4th rings yellowish dorsal spots; underneath these rings are whitish. Wings yellowish hyaline with fine black veins, margins, and discal spot. On the under surface the veins and the discal spot are orange-red. Expanse of wings: 24 mm. Brazil (Minas Geraes, Rio de Janeiro).

flavipalpe. **D. flavipalpe** *Hmps.* (26 k) differs from the preceding species by the orange-yellow palpi with a black terminal joint, the yellowish-white forehead, orange-red throat, black body with brownish, streak-like spots on the collar, shoulder-covers, and thorax. The abdomen exhibits above on the 3 first rings yellow spots. The forewings are purely hyaline, not yellowish. Expanse of wings: 24 mm. Argentina.

halteratum. **D. halteratum** *F.* (= *dieides* *Prittw.*) (19 e) differs from the preceding, similar species by the brown, not orange-red, colour of the tarsi and veins on the wings beneath, and the very fine, small middle dot being situate above the rise of the middle radial. From Venezuela and Brazil (Rio de Janeiro, Sao Paulo), very common also in Argentina and Paraguay, almost all the year round on compositae.

proleuca. **D. proleuca** *Druce* (19 e). Quite black, only the two first abdominal rings are yellowish-white. The hyaline forewings are somewhat yellowish; the very much reduced hindwings are black, with yellowish-white hair at the proximal margin. From Venezuela; before me also from Brazil (Sa. Catharina).

culex. **D. culex** *spec. nov.* (19 e). In this species the hindwings are the most extensively reduced, so that only by means of a magnifying glass we are able to discover yet a very small stump, whereas the forewings are most conspicuously broadened. The body is unicolorously brownish-black, the first abdominal rings beneath somewhat whitish. The wings are yellowish hyaline with a very narrow black distal margin; the costal margin and veins are brownish-orange. Only one somewhat mutilated example from the collection of the Museu Paulista from South Brazil.

Sect. II. Hindwings developed.

sylpha. **D. sylpha** *Dogn.* Head and thorax black, forehead and collar margined with white, the collar laterally red. Abdomen above with a dark greenish-blue lustre, beneath white, at the end black. Legs black, femora inside white. Wings hyaline with fine black veins and margins, at the rise of the middle radial a black dot.

The costa of the hindwings is white with a black stripe below it, being expanded towards the margin to such an extent that the whole rest of the wing turns black here. Expanse of wings: 25 to 27 mm. Ecuador.

D. chrysocraspis *Hmps.* (19 e) has a black body with an orange-yellow underside, and lateral spots *chrysocraspis* on the abdomen, varying in extent, the tarsi being orange, too. The proximal and costal margins of the forewings are orange; the costal margin of the hindwing is white. Bolivia.

D. doeri *Schaus* (19 e) has a black body; forehead and palpi anteriorly orange, collar and shoulder-covers striped orange, also the hips and tarsi. Prothorax laterally spotted carmine. The abdomen exhibits orange spots at the sides, the venter is quite orange. Wings hyaline with fine black veins, distal and proximal margin; at the rise of the middle radial a black dot. Costa of the hindwing white, below it a black stripe, fringes orange. Expanse of wings: 26 mm. Brazil (Sa. Catharina) to Paraguay.

D. philocles *Druce* (19 e) is recognizable by the black abdomen being spotted white laterally and ventrally. In front below the shoulders on each side a small red spot. The costal margin of the hindwing is white-haired. Panama (Chiriqui) and Brazil (São Paulo).

D. bivittata *Wkr.* (19 e) is striped in a bright orange on the sides of the blackish-brown abdomen, on the hindwings and shoulder-covers; the costal and proximal margins of the forewings also show orange-yellow stripes. Brazil (Santos); Paraguay; Argentina; nearly all the year round particularly on compositae.

D. aterea *Schaus* (19 e) strikingly resembles *bivittata*, but it has a whitish-haired proximal margin on the under surface. It differs besides from the said species by a much narrower black distal margin of the forewing; the proximal margin is entirely black, the orange colouring being confined to the extremest base. The hindwings are narrower, quite orange-yellow, only traversed by a black longitudinal stripe in the fold, and the margin black, fringes yellow, costa white, the proximal margin in the ♂ hyaline, with blackish hair. The body is coloured as in *bivittata*, but the extent of the orange colour seems to vary greatly: one ♂ is above almost entirely black, only the underside and tarsi being orange, whereas the ♀ lying before me is preponderantly orange. Brazil (Casa Branca; Matto Grosso).

D. aurantiipes *Rothsch.* Body, legs and antennae orange, thorax marked yellow and black, the two first abdominal rings are margined black. Wings yellow-reddish hyaline with orange-brown margins and discal spots. Length of forewings: 11 mm. Amazon.

D. hoffmannsi *Rothsch.* Body unicolorously blackish-brown, legs orange. Wings yellow-reddish hyaline, the distal half of the costa orange, the proximal half hyaline, the distal margin brown, the proximal margin red-brown. Length of forewings: 14 mm. Peru.

D. crassum *Zerny* differs by much broader hindwings from all the other species. Black, abdomen with a blue reflection. Yellow are the two first joints of the palpi, the sides of the head, and shoulders, on the abdomen above the rings 5 to 7 with a broad, black median band; the whole ventral side is yellow, the legs yellow and black. Antennae very long-combed, abdomen broad and stout. Wings faintly yellowish hyaline with fine black veins, margins and apical spots. Expanse of wings: 28 mm. Colombia (Bogotá).

75. Genus : **Syntrichura** *Btlr.*

Antennae thickened in the middle and above roughly haired. Second and third abdominal rings strangulated. On the forewings the lower radial vein is absent; the middle one rises below the middle of the discocellular. The 3rd and 1st subcostal veins rise at the same place from the 4th, the 5th from the cell. On the very narrow hindwings with a long discocellular, the third radial vein is likewise absent, the 1st median and middle radial vein rise from the lower cell-angle, the upper radial from below the upper cell-angle.

S. melaena *Dogn.* (19 f) is easily recognized by the unicolorously black body; only on the head and collar there are scarce whitish, tiny hairs interspersed. The last quarter of the antennae and a dot below their base are white. Peru (Cajon; Hillapani).

S. placida *Druce* (19 f) has a black body. The front side of the palpi and dots on the forehead are white; vertex and collar with a bluish-green lustre; prothorax laterally spotted carmine. Wings hyaline with fine black veins and margins. Expanse of wings: 22 mm. Guatemala.

S. virens *Btlr.* (19 f) has a bright bluish-green lustre on the body; the abdomen exhibits above on the strangulated segments a white dorsal stripe and lateral and ventral spots. — In *reba* *Druce* the prothorax is spotted carmine. Both the forms fly in French Guiana and Brazil, the latter was also found in Colombia, Venezuela, and to the north as far as Panama (Chiriqui).

76. Genus: **Herea** Wkr.

The differences from the preceding genus are to be found in the abdomen being suddenly expanded behind the rather considerable strangulation, and exhibiting lateral tubercles at the base. On the hindwings the discocellar is very short, the subcostal and first radial vein are on a joint pedicle, all the rest as in *Syntrichura*.

meta-xanthus. **H. metaxanthus** Wkr. (19 f). The body is black; beginning from the 4th ring, the abdomen is orange-yellow with a black median stripe; anal hairing and lateral lines on the penultimate ring black. Wings hyaline with fine black veins and margins; the proximal margin of the forewing and costal part of the hindwing more grey. Expanse of wings: 28 mm. Amazon (Pará).

prittwitzi. **H. prittwitzi** Möschl. (= *xanthogaster* Druce) (19 f). This small species has a black body with an orange-yellow venter and lateral stripes on the abdomen; the palpi are anteriorly whitish, of the same colour the middle of the anal hairing underneath. French Guiana, Bolivia.

ruficeps. **H. ruficeps** Wkr. (= *collaris* H.-Schäff.) (19 f) is easily recognized by the orange-brown head and collar, the rest of the body being black; the orange colouring may be extended to the prothorax and the base of the shoulder-covers. Tips of antennae, forehead and the first ventral segments are white. In the ♀ the black discal spot on the forewing is usually more developed. Distributed from Guiana to the Amazon.

77. Genus: **Eumenogaster** H.-Schäff.

Most of the species of this genus greatly resemble *Pseudospheex* from which, however, they are immediately distinguishable by the well developed neuration of the hindwings. They are characterized by their long-haired palpi, roughly and long-haired thorax and legs. The first abdominal ring exhibits lateral tubercles, followed by a great strangulation; the last segments have lateral hair-tufts. On the forewings the lower radial is present and rises, with the middle radial, from the lower cell-angle, while on the hindwings it is absent; the two median veins and the middle radial rise separately, the subcostal and first radial from the upper cell-angle.

notabilis. **E. notabilis** Wkr. (19 f) is easily recognized by the broad, brown proximal and distal margins of the faintly yellowish hyaline wings, the costal margin being striped red or orange, and between the transverse vein and apex there are scant black and red scales interspersed. The body is anteriorly blackish-brown, striped and spotted yellow, the abdomen red, posteriorly more brown, the strangulated rings black, in the middle yellowish-white. From Guiana to the Amazon (Pará). — v. **caurensis** Klages from Venezuela differs but slightly by somewhat more pronounced yellow hair on the collar and shoulder-covers, white spots on the anterior and posterior hips, as well as at the extremest end of the anterior femora; the yellowish-white spots on the first abdominal rings are silvery white.

pseudopolybia. **E. pseudopolybia** Schrottky. Head black and yellow, antennae black, forehead metallic blue, palpi with dark yellow hair. The black thorax, with a blue lustre, is marked yellow. Legs black, hips and tarsi yellow haired and scaled. Abdomen black, with a blue lustre, the 4 first rings with yellow bands, on the ventral side much broader and more extensive. Wings yellowish hyaline with dark brown veins and margins. Expanse of wings: 20 mm. Paraguay.

pseudosphecia. **E. pseudosphecia** Hmps. (19 g) has, like the following, scarlet antennae, but a reddish-brown abdomen, the 3rd segment exhibiting a whitish band. The anterior body is black, marked yellow, the forehead white. The costal-marginal half of the forewing is greatly darkened by brown scales. From the Amazon (Pará; Teffé).

affinis. **E. affinis** Rothschild. differs from *pseudosphecia* by its white forehead, light brown thorax, dark red-brown metathorax and base of abdomen; the other abdominal rings are black, not red-brown; the costal part of the forewing is dusted more scarlet. Venezuela.

nigricauda. **E. nigricauda** Dogn. Head black, forehead white, vertex, collar, and palpi yellow; shaft of antennae scarlet, at the base yellow. Thorax marked black and yellow; the first 4 abdominal rings are ochreous-yellow, the following ones black. Underneath the 3rd and 4th rings are white, the 3 last ones black, the others yellow. Hips white, legs yellow with black ankles. Wings yellowish hyaline, in the costal half darker yellow; fringes and proximal margin above fine black, below yellow. Expanse of wings: 28 mm. French Guiana.

E. haemacera *Hmps.* (19 g). Black, the antennae are above scarlet, except the black base; forehips, *haemacera*, the second segment and the basal half of the third ventral segment white; on the 3 first abdominal rings lateral white and yellow streaks. The hyaline wings with fine brownish veins and margins are tinted orange-brownish in the costal-marginal half. Venezuela, Guiana, Amazon.

E. eumenes *H.-Schäff.* (19 g). Body black; tips of antennae white; the abdomen exhibits lateral *eumenes*, white stripes on the 3 first rings. The costal halves of the hyaline wings are yellowish, the veins and margins narrowly black. Expanse of wings: 34 mm. Surinam; Brazil.

78. Genus: **Urolasia** *Hmps.*

Palpi not so long-haired as in the preceding genus, the abdomen only very little strangulated, but also with lateral hair-tufts and a large anal tuft. On the forewings the upper median and the 2 lower radial veins rise separately; on the hindwings the middle median vein is nearer to the lower cell-angle from which the 1st median and the middle radial vein rise, the lowest radial being absent.

U. opalocincta *Druce* (19 g). Body black, on the forehead, collar, shoulder-covers, hips, and meta-*opalocincta*, thorax metallic blue spots—the strangulated abdominal rings exhibit subdorsal, white, intensely opalescent bands and a silvery white underside, on the 5th and 6th segments sublateral silvery spots. The black marginal band of the forewing expands greatly towards the proximal angle, the hindwings are broadly bordered with black, the border growing narrower towards the proximal angle. French Guiana.

U. albipuncta *Druce* has a bluish-black body with a white forehead. The base of the abdomen, dorsal *albipuncta*, and sublateral rows of spots on the abdomen are white. Wings hyaline with a black distal and proximal margin and apex. Expanse of wings: 32 mm. Venezuela.

U. brodea *Schaus* (19 g). The body is black, the abdomen above with bands of a blue lustre, *brodea*, beneath at the base with a white median stripe. Anterior side of the palpi, sides of the forehead, spots on the shoulders and hips white. Thorax and legs spotted blue. Wings hyaline with broad, black margins. Expanse of wings: 30 mm. Trinidad.

79. Genus: **Sesiura** *Hmps.*

By the abdomen being slightly strangulated only at the 5th and 6th segments and then growing broader again, the only species is separated from the preceding genus; lateral hair- and anal tufts as there; on the forewings the two lower radial veins rise contrariwise in common, on the hindwings the upper median and the middle radial vein rise separately, the lowest radial being absent.

S. smaragdina *Wkr.* (= *saturatissima* *Wkr.*) (19 g) looks like a small *Aethria leucaspis* *Cr.* and is *smaragdina*, coloured and marked exactly the same way, but the white spots on the abdomen are absent. — Here the red anal tuft may also turn yellow: **flava** *form. nov.* (= *ab. 1. Hmps.*) (19 g). — Both forms are widely distributed *flava*, from Venezuela, Guiana as far as the Amazon.

80. Genus: **Metastatia** *Btlr.*

In the veins no essential difference from *Sesiura*, only the uppermost subcostal vein does not rise from the cell, but in common with the other subcostal veins. The abdomen is somewhat strangulated at the second segment, the last ring exhibits lateral hair-tufts. The posterior tibiae are considerably expanded.

M. pyrrhorhoea *Hbn.* (19 h). Anterior body black, spotted white, the abdomen with a deep blue lustre *pyrrhorhoea*, and with dorsal and lateral lines composed of white spots; anal tuft earmine; venter spotted white. The black forewings, with a slight blue lustre, exhibit a large, triangular, hyaline area in the basal half, and a postdiscal band; the hyaline hindwings a broad, black border; fringes at the anal angle white. British and French Guiana, Amazon.

M. azurea *Lathy* differs from the preceding by its more extensive hyaline spots, a much brighter *azurea*, blue, the absence of white spots on the shoulders and prothorax, the shoulder-covers not being bordered with white, the ventral side being quite unicolorously greyish-white; beside the anal tuft, the whole last abdominal segment is earmine. Ecuador.

81. Genus: **Abrochia** H.-Schüff.

A considerable number of small to almost medium-sized, neat species being mostly coloured yellow on the body and resembling *Sphecosoma* or small *Cosmosoma*-species by their exterior, but being at first sight recognizable by the veins of the hindwings. The first palpal joint long-haired; the female antennae rather thickened in the middle, serrate-dentate, those of the ♂♂ doubly combed; the second abdominal ring is strangulated. On the forewings, the upper median and the lower radial veins rise separately, the upper radial from the upper cell-angle, the 1st subcostal vein from the cell. The cell of the hindwing is long, the lower radial being absent; the upper median and middle radial vein rise separately, the subcostal and the uppermost radial vein from the upper cell-angle.

- faveria*. **A. faveria** Druce (19 h) differs from the following by an orange-yellow discoidal spot and large, faded black apical and inner-marginal spots on the forewings. From Panama (Chiriqui).
- dycladioides*. **A. dycladioides** Heyl. (19 h) is a peculiar species from Brazil (São Paulo), being very much distinguished by a remarkably large, round, black discoidal spot of the forewing. The body is orange, the head and last abdominal rings black, the anal hair with a leaden lustre. The legs are orange, tarsi and posterior tibiae black, posterior tarsi partly yellow. The veins and margins of the basal parts of the wings are yellow, the rest black.
- humilis*. **A. humilis** H.-Schüff. (19 h). Head and collar black, thorax orange. The 2 first segments and the legs of the 3rd abdominal segment are orange, the others black, posteriorly margined by blue. Wings hyaline, veins and margins of the proximal halves orange, distally black, as well as a broad apical spot. Hindwings with orange veins and margins and a black apical spot. Expanse of wings: 28 mm. Brazil.
- cosmosomoides*. **A. cosmosomoides** Rothsch. Head and thorax black; forehead, palpi, thorax and legs golden yellow; antennae black, in the middle brownish orange; the distal half of the collar and the shoulder-covers orange-yellow, the latter bordered with black. On the thorax 2 golden yellow middle spots. The 2 first abdominal rings are golden-yellow, the others steel-blue, bordered with golden yellow. Forewings yellowish hyaline, the distal two thirds of the costa and the median deep orange, the other veins and margins and a broad apical spot sooty black; hindwings very small, yellow hyaline with black veins and fringes. Expanse of forewings: 14 mm. Venezuela.
- augusta*. **A. augusta** Druce (19 h). Head and thorax black, on the vertex and collar spotted blue; base of shoulder-covers yellow. Legs yellow, tarsi and anterior tibiae black. Forewings hyaline, base, costal and proximal margin black; veins and margins in the middle area yellow. Discal and apical spots, as well as the veins in the marginal area are black. On the hindwings the veins in the basal area are black, distally yellow. Expanse of wings: 26 mm. Mexico; Guatemala.
- sanguitarsia*. **A. sanguitarsia** Hmps. (19 h) is a true copy of *Eumenogaster haemacera* (19 g) from which it differs by the hemochrome tarsi. Body black, at the second abdominal segment laterally and beneath, on the two following ones beneath spotted white. Antennae hemochrome. The hairing of the palpi, forehead and thorax is sparsely intermixed with orange hairs. The wings are also here reddish-brown in the costal halves; the costal-marginal veins of the hindwing are red. Bolivia (Rio Songo).
- postica*. **A. postica** Wkr. (19 h). Head, mesothorax, the first and last abdominal rings are black, the latter more or less with a leaden grey lustre; base of palpi, sides of thorax, and shoulder-covers, as well as the middle abdominal rings are orange. The wings are narrowly bordered with black. Amazon (Pará).
- pelopia*. **A. pelopia** Druce (19 h) differs from the following by the veins being entirely black, and the collar being anteriorly orange-yellow, the metathorax and ends of the shoulder-covers being orange, too, as well as the 5 first abdominal rings. Panama; Bolivia.
- mellita*. **A. mellita** Schaus (19 i) somewhat resembles *pelopia*, though it is easily discernible by the veins and margins being yellow in the basal halves of the wings. Anterior body black with silvery blue spots of a lilac iridescence on the vertex and collar. The 2nd to 5th segments of the abdomen are yellow, the rest being black, the last segment with a silvery blue and purple lustre. Underside and legs yellow, tarsi black. Both wings exhibit large, black apical spots. Described from Costa Rica (Sixola); the figure according to a specimen of the Coll. FASSL from Muzo (Colombia); it, therefore, seems to be widely distributed.
- tetrazona*. **A. tetrazona** Hmps. (19 i). Body black; base of palpi, sides of forehead and vertex spotted orange; collar, shoulder-covers and thorax scaled orange; the first abdominal ring is subdorsally spotted orange; the second strangulated segment is quite light yellow, the following 4 rings are banded orange. The proximal margin of the hindwing orange. The ♀ differs by yellowish wings, a large, orange and black discal spot and a brown spot below the apex of the wing. Bolivia (Rio Songo); Amazon (Pebas). — **obsoleta** *subspec. nov.* (= subsp. ♀ Hmps.) is a female form from Brazil (Minas Geraes), in which the orange bands on the abdomen have disappeared; the discoidal spot of the forewing is absent, too.

A. julumito *Dogn.* (19 i) is characterized by very large, black apical spots of the forewing. The *julumito*. head is quite scarlet, the antennae black, palpi yellow. Collar, shoulder-covers and thorax yellow with fine black margins. The abdomen is orange-yellow with a black median line, beginning from the 5th ring black with a leaden lustre, the segments 3 and 4 finely bordered with black. Underside and legs are quite yellow. Described from Ecuador (Loja), before me also from French Guiana (Nouveau Chantier).

A. sanguiceps *Druce* (19 i) is larger than the preceding, of a more intense orange colour, only the *sanguiceps*. vertex being red, with black spots, the other part of the head orange; the mesothorax is extensively black; the forehips are spotted blue, the middle tarsi striped black; only the two first abdominal segments are orange, the others black, the 3rd to 5th laterally spotted orange. French Guiana.

A. singularis *Wkr.* (19 i) is easily distinguished from *sanguiceps* by the black head and anterior half *singularis*. of the thorax; besides, the abdominal end is only faintly tinted blackish, so that the orange colour shines through. Amazon (Pará).

A. discoplaga *Schaus* (19 i) is black on the head, collar and most anterior part of the thorax, the *discoplaga*. vertex and base of the collar spotted silvery blue with a violet iridescence; the rest of the body is ochreous yellow, the 2 last abdominal segments black. Underside and legs yellow, tarsi partly black. On the hyaline wings the basal half of the costal margin, the median, vein 2, the base of vein 3, and the proximal margin are yellow; the rest of the veins and margins, as well as a large discal spot are black; the veins of the hind-wings are yellow, the margins black, the proximal margin with ochreous-yellow hair. Venezuela; also from French Guiana (St. Jean Maroni).

A. sodalis *spec. nov.* (19 i) is very closely allied to the preceding and differs at once by the quite *sodalis*. black veins, the black, narrow proximal and costal margins, the absence of the discal and apical spots; only the extreme base of the wings is yellow. The last three abdominal rings are black, also underneath, whereas in *discoplaga* the ventral side remains yellow. — From the original description of the latter which is before me only in a female example, the sex is not to be inferred; it is, therefore, not impossible that *sodalis* of which there is a male before me from French Guiana, is the dimorphous ♂ of *discoplaga*.

A. consobrina *Wkr.* (19 i). Body orange-yellow, head and thorax marked black; the first abdominal *consobrina*. segment exhibits black dorsal and subdorsal streaks, the last rings are blackish-brown with a purple lustre. The hyaline wings do not show any black spots at the apex and proximal angle; the base of the costal margin is orange. Amazon.

A. mellina *H.-Schäff.* (19 k) has a yellow body. The hindhead is carmine with 2 white dots. A spot *mellina*. in the mesothorax and the borders of the shoulder-covers are black. Abdomen with black articular lines and median stripe, the latter being on the last ring expanded like a spot. Wings hyaline with fine black veins and margins; the forewing with yellow stripes at the costa and proximal margin; both wings with black apical spots. Expanse of wings: 24 mm. Venezuela; Pará.

A. igniceps *spec. nov.* (19 k) differs from the preceding by only the upper part of the forehead *igniceps*. being scarlet; the hindhead itself is yellow with a black middle spot; the collar is bordered with black; the spot-like expansion of the middle line on the last segment being absent. There is no black apical spot on the wings which are but extremely finely bordered with black; the distal half of the proximal margin of the forewing is yellow; costal and proximal margins otherwise black, only at the base spotted in a lemon colour. Hips spotted metallic bluish-green, legs yellow, only the posterior tibiae and femora, as well as all the tarsi above striped black. Described according to a ♂ from Peru (Marcapata, BANG-HAAS).

A. atridorsata *Hmps.* differs from *mellina* (19 k) by the orange-yellow spot being spotted black on *atridorsata*. the vertex, without any red, by the whitish ends of the antennae, the absence of the black articular lines on the abdomen. The black dorsal stripe forms transverse bands on the 2 last rings. On the forewings the costal margin is not orange. Expanse of wings: 26 mm. British Guiana.

A. munda *Wkr.* (19 k) has an entirely orange-yellow body, the dorsal stripe running through across *munda*. the thorax and abdomen; each abdominal ring is black-curved, the collar and shoulder-covers are bordered with black. There are no discal nor apical spots on the wings. Amazon (Pará).

A. fulvisphex *Druce* (19 k). Body orange yellow; forehead, collar, shoulder-covers and thorax striped *fulvisphex*. black; the four first abdominal rings exhibit a black median line with small, leaden-coloured spots in it, the third and fourth segments are finely bordered with black; black lateral spots on the middle segments. The hyaline wings have no discal spot, an orange-yellow costal and proximal margin. French Guiana (Cayenne; Nouveau Chantier).

A. aequalis *Wkr.* (19 k) is recognizable by the orange-yellow discal spot of the forewing and by the *aequalis*. shoulder-covers in the middle, the thorax and collar being striped black; the whole body is orange-yellow, the antennae at the base black, otherwise orange. Costal and proximal margins of the forewings are orange, the fringes brownish. Venezuela; Amazon.

zethus.

A. zethus *Hbn.* (19 k). Body yellow and orange; palpi, vertex, and thorax banded black, as well as the borders of the collar and of the shoulder-covers. Wings hyaline, with fine black veins and borders, at the costa and proximal margin striped orange, the fringes brownish. Expanse of wings: 30 mm. Pará; Argentina.

moza.

A. moza *Druce* (19 k) is the only species known hitherto with an almost entirely black body exhibiting a red anal tuft; the second strangulated segment is laterally and beneath white, and besides, the sides of the forehead, the shoulders, the metathorax and the hips are spotted white. The yellowish hyaline wings show a red costal-marginal stripe and black narrow margins. Panama (Chiriqui).

82. Genus: **Pseudargyroeides** *Klages*.

Distinguished from the preceding by shorter palpi, the shaft of the antennae being thickened in the middle also in the ♂, the anterior and middle tibiae being roughly scaled; not only the 2nd, but also the 3rd abdominal ring strangulated. On the forewings the uppermost radial vein rises from below the upper cell-angle, otherwise as in *Abrochia*. Only one species.

caurensis.

P. caurensis *Klages* greatly resembles *Argyroeides suapurensis*. The body is blackish-brown; palpal ends anteriorly orange. Spots on the sides of the forehead, neck, collar, thorax, as well as the borders of the shoulder-covers yellow-haired. Behind the eyes metallie green stripes, on the metathorax a lustrous blue spot. The 2 first abdominal rings above spotted yellow, the 3 next ones margined by yellow. Wings yellowish hyaline, veins and margins blackish-brown, so is a discal streak and an apical spot, the proximal margin of the hindwing black-haired. Expanse of wings: 29 mm. Venezuela.

83. Genus: **Ecdemus** *H.-Schäff.*

The erect palpi extend just as far as the vertex. The cell of the forewing is very long, narrowed towards the apex, so that the transverse vein grows very short. The median veins and the lower radial vein rise in long interspaces before the lower cell-angle, the upper radial from below the upper cell-angle, the 3 lowest subcostal veins petioled, both the upper ones from the cell. On the hindwings it is just the same: the median and lower radial veins all rise at about the same distance from each other, the transverse vein is very short; the subcostal vein and the uppermost radial vein rise here long-petioled. Only two species known.

hypoleucus.

E. hypoleucus *H.-Schäff.* (19 k). Body black, throat orange-yellow, hips and venter as far as the 5th segment white, like the anterior side of the palpi and spots at the ends of the middle and posterior tibiae. Recognizable by the broad black costal margin between the cell-end and middle radial. From French Guiana as far as the Amazon (Pará).

obscuratus.

E. obscuratus *Schaus* differs from the preceding chiefly by the great expansion of the black costal and distal margins, whereby the hyaline spots are greatly reduced, which are besides thinly scaled blackish. Base of palpi ochreous-yellow and white. Abdomen above bluish-black, beneath white. Costa Rica.

84. Genus: **Agunaix** *Hmps.*

The first palpal joint long-haired; on the forewings both the lower radial veins rise from the lower cell-angle, the upper one from far below the upper cell-angle; very characteristic is the course of the subcostal veins, all of which rise at the same distances from the lowest. On the hindwings the median and lower radial veins all rise rather closely together, the subcostal and upper radial vein are petioled; the distal margin is concavely indented near the anal angle.

lacrumans.

A. lacrumans *Schaus* (19 l). The only species is an insignificant insect with very long, narrow wings, being thinly scaled blackish and a black abdomen. The basal half of the forewing is more densely scaled than the rest. From Peru and Bolivia; a female example is also before me from the Coll. FASSL, from West Colombia, Rio Aguaca Valley, 2000 m.

85. Genus: **Cercopimorpha** *Bllr.*

Palpi erect with an obtuse terminal joints; tibiae with rather long spurs; abdominal base above roughly haired. On the forewings both the lower radials rise from the lower cell-angle, the 1st subcostal vein from the cell. On the hindwings the lower median and upper radial vein stand on a joint pedicle, the middle radial rises above it, the subcostal and upper radial vein likewise petioled.

C. tetragonia *Hmps.* (191). Anterior body blackish-brown, abdomen above metallic blue, beneath *tetragonia*. white with a black anal tuft. Forehead and anterior side of the palpi white; neck and prothorax earmine, shoulder-covers striped orange. The brown forewings show in the cell-end a square, orange-red spot, the hindwings are in the centre hyaline diaphanous. The basal halves of the wings are on the under surface suffused by metallic blue on the costa and median. So far only known from Venezuela (Merida).

C. homopteridea *Btlr.* (= *peetinata Wkr.*) (191). Blackish-brown; palpi at the articular ends white. *homopteridea*. Vertex, collar, and shoulder-covers striped grey. Neck and abdomen orange, the 1st segment and the anal tuft black. Forewings blackish-brown, with short, white, small stripes below the costal base and median; before the apex is a faded grey spot and before the margin an indistinct, white, dentate line. Hindwings blackish-brown, in the disc diaphanous. Expanse of wings: 30 mm. Pará.

C. meterythra *Hmps.* (191) is very easily recognizable by the red hindwings being bordered with black; *meterythra*. the brown forewings exhibit hyaline spots in the cell-end and above and below the lower radial vein. The body is black, on the abdomen subdorsally spotted blue with a white ventral side; neck red, palpi and legs white striped. Known from Bolivia.

86. Genus: **Teucer** Kirby.

The ♂♂ of this genus are mostly distinguished by secondary sexual marks in the shape of accumulations of rough scales on the under surface of the wings, as well as by lobular or pointed prolongations of the anal angle on the hindwing. The veins on the forewings are not quite constant in the different species and do not offer any characteristic marks. On the hindwing the 1st radial and the subcostal stand on a short pedicle, in some species the costal vein is rudimentarily present.

T. subplena *Wkr.* (191) is distinguished by the carmine, last abdominal segments, the body being *subplena*. otherwise blackish-brown, the hindhead spotted red; hips and venter are white, the anus ochreous-yellow. The brownish-grey forewings with olive-grey striped veins are spotted black and exhibit in some places more thinly scaled, lighter patches. The hindwings are black with small hyaline spots in and below the cell and yellowish-white spots at the proximal margin. Brazil (Rio de Janeiro).

T. distincta *Rothsch.* Body brownish-black; collar, last abdominal ring, underside and forehips brick-red, on the metathorax a chrome-yellow band. Forewings brownish-black with large hyaline spots in and below the cell and 2 behind it, below and above the upper radial vein. Apex white; the veins of the apical half and a transverse line in the marginal area grey. Hindwings hyaline with a very broad black border. Surinam.

T. brevipennis *Btlr.* (191). Head and thorax brown and blackish; in the neck there are 2 orange *brevipennis*. spots; hips white. Abdomen blackish, at the apex grey, the venter white. Forewings blackish-brown, on the veins dusted ochreous. Hyaline spots in and below the cell and 4 behind it between the 1st median and lowest subcostal vein. Before the border is an indistinct, ochreous-yellow line. Fringes at the apex, on the middle radial and between the median veins white. Hindwings black, with hyaline stripes at the base, the fringes and the rough scaling of the under surface white. Expanse of wings: 24 mm. Amazon.

T. hypophaeus *Hmps.* (191) greatly approximates the preceding species and is distinguished by *hypophaeus*. the somewhat grey, spotted brightening of the distal half of the forewing, the ochreous-yellowish dusting being absent; the transverse vein appears in the grey discal spot as a grey line, the ochreous-yellow line before the margin is absent, and there is a small hyaline spot besides, above the lower median vein. On the under surface of the hindwing the rough scales are yellowish-grey, the inner-marginal area being white. Venezuela and French Guiana.

T. germanus *Rothsch.* differs from *hypophaeus* by much smaller hyaline spots of the forewings and *germanus*. quite black hindwings with a sooty-grey proximal angle; only at the base 2 small grey, diaphanous spots. The under surface of the hindwings is quite sooty black with minute, transparent basal spots. Length of forewings: 12 mm. Venezuela.

T. apicalis *Rothsch.* The body is black, vertex and forehips orange; legs blackish-brown. Forewing *apicalis*. in the proximal two thirds black, in the marginal third yellowish-grey with black, interrupted longitudinal stripes on the veins; spots in and below the cell and 2 behind it are diaphanous grey. Hindwings in the basal half diaphanous white, distally blackish-brown, towards the proximal angle yellowish-grey. Length of forewings: 16 mm. Surinam.

T. albapex *Druce* (191). Black; anterior side of the palpi, hips and stripes on the femora white; *albapex*. abdomen with a blue lustre, with white lateral stripes, venter white. The hyaline forewings with broad, black veins exhibit very broad black margins and discal spots, the extreme apex being narrowly white; the black hindwings exhibit in the middle a hyaline stripe extending almost to the margin. French Guiana.

- glaucopis.* **T. glaucopis** *Fldr.* (20 a) is a larger, well recognizable species with a blackish body; hindhead and collar spotted carmine; anterior side of the palpi, forehead, thorax, shoulder-covers and base of the femora spotted white. The abdomen shows large, white, lateral and ventral spots. The blackish-brown forewings are of a lighter whitish behind the cell, with black veins, the hindwings hyaline with a blackish-blue border. Distributed from French Guiana to the Amazon District and not rare. — In a male example from Colombia *obsoleta*. (Coll. SEITZ) from the Rio Dagua the white lateral spots on the abdomen are absent altogether: f. **obsoleta** *form. nov.*
- carmania.* **T. carmania** *Druce* (20 a). Black; anterior side of the palpi, sides of the forehead, and forehips white; abdomen beneath almost as far as the apex white. Forewings with 2 hyaline stripes in the cell, one below it and 3 more between the lower median and radial vein. Hindwings hyaline with a black border. Expanse of wings: 28 mm. Ecuador.
- rubrothorax.* **T. rubrothorax** *Rothsch.* differs from *carmania* by the entirely carmine thorax, much smaller and entirely black hindwings with a white costal base. Length of forewings: 11 mm. Amazon.
- brunnea.* **T. brunnea** *Hmps.* The body is dull red-brown, in the neck orange. The abdomen exhibits, from the 5th to 7th rings, orange subdorsal spots and white sublateral stripes. The red-brown forewings exhibit a discal dot on the dark middle band being angled at the lower cell-end and before the border a light dentate line. Expanse of wings: 26 mm. Argentina.

87. Genus: **Epanycles** *Btlr.*

Shaft of antennae in the middle somewhat thickened. The first radial and subcostal vein of the hindwing petioled, the middle radial rising from above the lower cell-angle; the proximal margin of the ♂ beneath shows a long hair-tuft. On the forewings the upper median and the lower radial veins rise from the lower cell-angle, the 1st radial vein from the upper angle, being strongly bent downward. Only one rather dark species:

- imperialis.* **E. imperialis** *Wkr.* (20 a). The forewings are brown with a purple violet lustre, at the base of the costal margin a brassy-green spot; hindwings grey, in the disc diaphanous. The body is blackish-brown with brassy-green spots particularly towards the anus. Known from Guatemala, Venezuela, Guiana, Amazon (Pará) and Peru.

88. Genus: **Pterygopterus** *Btlr.*

Only few large, dark-coloured species, the ♂♂ with a long-extended proximal angle of the hindwings, and long hair-tufts at the same place. The cell of the hindwing is long, the lower median vein rises afar from the cell-angle, the upper median and lower radial vein from its lower corner, the middle radial from below the middle of the discocellular.

- leucomelas.* **P. leucomelas** *Wkr.* (= *superbus Druce*) (20 a) is a magnificent, large species, which is unmistakable by the large, white apical spot being margined by black, whereby it most strikingly copies large Ichnumonids. On the forewing, being otherwise deep velvety-black, turning somewhat brownish towards the margin, the metallic blue median vein is very prominent; at the base, above vein 1, there is besides a blue spot; the hindwings are blackish-blue, at the apex metallic blue. Body bluish-black; tips of antennae orange. Widely distributed from Panama, Guiana, Colombia (Muzo) as far as Brazil (Pará).
- flavicornis.* **P. flavicornis** *Kaye.* This species having been described according to a ♀, is said to differ from *clavipennis* only by its entirely orange-yellow antennae, as well as by the rounder contours of the ♀♀ hindwings, the proximal angle not being extended. It may be the ♀ of *clavipennis* which has not become known hitherto. British Guiana.
- clavipennis.* **P. clavipennis** *Btlr.* differs from *caeruleus* by the antennae being orange-yellow only in the terminal third, and by the abdomen exhibiting a metallic green lustre at the base and sides. Forewings bluish-black, at the costal margin, in the inner half of the proximal margin and below the cell-end greenish, in the marginal area brown, at the base and at the end of the median, and at the base of the inner-marginal vein metallic green. Hindwings bluish-black, costa and veins metallic green. Expanse of wings: 48 mm. Brazil.
- caeruleus.* **P. caeruleus** *Hmps.* (= *clavipennis Druce*) (20 a) is a large, blackish-blue species with an intense, bronze-brown lustre on the forewings, a metallic blue spot at the base and a faintly blue median. On the under surface the veins are suffused by blue. Antennae black, the two terminal thirds orange. Head, metathorax, legs and abdomen with metallic blue spots. Apparently a rare species, having hitherto only been found in Mexico (Jalapa, Orizaba) in October.

89. Genus: *Episcepsis* Btlr.

Species of medium to big size, with a preponderantly dim colouring of the wings, usually with metal-colours on the abdomen. The forewings, being rather broad, exhibit the usual neuration, the hindwings mostly show in the ♂ a long hair-tuft in an anal fold of the proximal angle being here often extended to a point. The lower median vein rises far from the lower cell-angle, the upper median vein and the 3rd radial from it, the middle radial distinctly from above it. The base of the abdomen is covered with long hair.

E. melanitis Hbn. (20 b) is an entirely deviating type, which at first sight does not look at all like *melanitis*. a Syntomid. The velvety deep blackish-brown forewings exhibit a broad, orange-yellow, oblique band; on the under surface both wings are suffused with a metallic blue in the basal halves. The body is blackish-brown, palpi and legs striped white, the venter shows sublateral series of white spots. The hair-tufts on the abdomen and proximal margin of the hindwings are white. British and French Guiana.

E. lenaeus Cr. (20 b). Head, thorax and forewings dark sepia-coloured, the latter with a white apical *lenaeus*. spot; the hindwings in the disc diaphanous, otherwise slate-coloured. In the neck 2 carmine spots. The bright red forehips separate the species easily from the very similar *thetis*. Abdomen above metallic blue, the hair at the base blackish-brown. The hair-tufts in the anal fold white in the ♂. Distributed from Mexico through Central America as far as Guiana and Surinam.

E. thetis L. (= *thoos* F., *lenaeus* Druce pr. p.) (20 b) has a white apical spot on the forewings, white *thetis*. forehips and first palpal joint; hindhead and shoulders are spotted carmine; on the brown forewings the veins are not lighter prominent; the first 3 ventral segments are spotted white; the hair-tufts at the proximal margin are yellowish. Occurring from Panama, Venezuela as far as Argentina.

E. hampsoni Roths. greatly approximates *thetis* from which it differs by its black palpi and forehips *hampsoni*. (the latter show some white only at the base), orange-yellow neck, distinctly light grey veins particularly in the basal half of the forewing and snow-white hair-tuft in the ♂. The venter is unicolorously sooty black. Length of forewings: 18 mm. Surinam.

E. capysca Schaus. This species, and the following, so strikingly resemble *Patreliaura capys*, that one *capysca*. must look very closely in order to distinguish them; the principal distinguishing mark are of course the unpetioled upper median and lower radial veins of the hindwing and the rise of the upper radial of the forewing from the upper cell-corner. Besides, the base of the palpi is white, and the abdomen beneath spotted white, the whole animal being somewhat larger, at an average. The head is ochreous-yellow, spotted black, the forehead blackish with some white scales. The blackish-blue hindwings exhibit a hyaline spot in the cell, below and behind it. Costa Rica (Tuis).

E. capyscoides Dogn. (20 b) is perhaps only a local race of the preceding, chiefly differing by the *capyscoides*. presence of a white, diaphanous spot on the inner-marginal base of the hindwing; only the hindhead is orange. The species described from French Guiana is before me also from Bolivia.

E. rhypperas Hmps. (= *lenaeus* Druce pr. p.) (20 b) is somewhat smaller than the very similar *thetis*; *rhypperas*. on the forewings the veins appear lighter; hindhead and shoulders are spotted orange, not carmine, the venter is much more extensively white; the hair-tufts at the proximal margin are entirely white. British Honduras.

E. gnoma Btlr. (20 c) and the following are easily distinguished from the numerous similar species *gnoma*. by the white forehips. Shoulders and hindhead spotted red, the lower end of the collar not. The abdomen is of an intense metallic blue, the 3 first segments beneath spotted white; the light veins of the wings form the only difference from the following species. From French Guiana, the Amazon and Rio de Janeiro.

E. gnomoides Schaus exactly resembles the preceding, but the veins of the forewings are black and *gnomoides*. not lighter than the ground. Costa Rica (Sixola River).

E. klagesi Roths. differs from *gnoma* by the white apical border and much more pronounced *klagesi*. light veins of the forewings, an orange neck and an entirely white ventral side. Venezuela.

E. sordidus Roths. differs from *klagesi* by its dirty dark brown forewings with lighter veins, the *sordidus*. apical fourth being whitish brown-grey, the abdomen above and beneath unicolorously black-brown. Venezuela.

E. vinasia Schaus. The body is brownish-black, palpi and legs striped grey; hindhead ochreous-yellow, *vinasia*. collar laterally spotted ochreous-yellow. Abdomen above metallic blue, with basal blackish-brown hair, beneath all white. Forehips ochreous-yellow. Forewings brownish-black with grey veins. Hindwings bluish-black, in and below the cell with a broad white longitudinal stripe from the base; the proximal margin striped white in the ♂ with a yellow-reddish hair-tuft. Expanse of wings: 32 mm. Costa Rica.

- lamia*. **E. lamia** *Btlr.* (20 c) is difficult to distinguish from the following species: the ground-colour is on the whole somewhat browner, the wings more stretched, more pointed, the surest distinguishing mark being a red spot on each side of the lowest end of the collar, without a red spot on the shoulders being present. Besides there are more or less distinct whitish sublateral lines at the base of the abdomen. Amazon. —
- flavomaculata*. In ab. **flavomaculata** *form. nov.* (= ab. 1. *Hmps.*) the red colour of the spots on the head and forehips has turned yellow.
- inornata*. **E. inornata** *Wkr.* (= *lamia Druce pr. p.*) (20 c) is unicolorously blackish-brown on the forewings. The forehips, as well as two small spots in the neck and below the shoulders are red. Abdomen above metallic blue, only the dorsal hair are brown, below all brown, not white-spotted. Hindwings blackish, in the centre diaphanous, the anal hair-tufts in the ♂ yellowish. Mexico, Guatemala, Costa Rica, Panama.
- dodaba*. **E. dodaba** *Dyar* (20 c) from Mexico (Santa Rosa, Orizaba: July to September), Venezuela and a ♂ from Ecuador, differs from the most similar *inornata* by the presence of a red spot on each side of the lower end of the collar, so that there are thus 3 pair of red spots next to each other: on the hindhead, collar, and shoulder. The venter is all black in the ♀, while in the ♂ the 3 first rings beneath are spotted white.
- redunda*. **E. redunda** *Schaus* (20 c) on an average is somewhat smaller and has rounder wings than *dodaba* which it extremely resembles. The colour of the forewings is a little more sooty, that of the hindwings somewhat more bluish. It differs besides by the absence of the red lateral spot on the collar, such a spot being only situate below the collar on the shoulder. The venter is spotted white, in contrast with *inornata*. From the following it differs by the more extensive white colour on the hindwing, extending beneath, in the shape of a broad longitudinal stripe, from the base almost to the margin. Most widely distributed from Mexico, Costa Rica, Trinidad, Venezuela, British and French Guiana as far as Peru.
- frances*. **E. frances** *Dyar* extremely resembles *redunda* (20 c) and differs by the entire absence of the white colour on the under surface of the hindwings, below the median the scaling is only somewhat thinner. Mexico.
- hypoleuca*. **E. hypoleuca** *Hmps.* (= *lamia Druce pr. p.*) (20 d) is separated from the very similar *inornata* by the black veins of the forewings and the white spots on the 3 first ventral segments. Costa Rica.
- dominicensis*. **E. dominicensis** *Rothsch.* Body of a deep sooty brown; collar and forehips orange. The last 2 abdominal rings have a metallic blue lustre. Forewings deep purple brown with a white apex. Hindwings sooty black, in the disc lighter diaphanous. Dominica.
- ockendeni*. **E. ockendeni** *Rothsch.* is a unicolorously sooty brown animal, the forewings slightly tinted violettish purple, the hindwings greyish-brown. Length of forewings: 20 mm. Peru.
- venata*. **E. venata** *Btlr.* (= *aelia Schaus*) (20 d). Forewings dirty whitish with brownish margins, veins and discoidal spots. Hindwings blackish, in the disc diaphanous. Body blackish-brown, abdomen towards the apex above suffused with blue. Forehips, as well as two spots each on the neck and shoulders are red. From Mexico: Jalapa, Tabasco, Misantla, taken in June; the type originates from the Amazon (Rio Jutahi).
- endodasia*. **E. endodasia** *Hmps.* (20 c) is on the body and forewings quite unicolorously blackish-brown, only the hips and the anterior half of the venter are yellowish-white. The blackish-grey hindwings are semi-diaphanous in the disc, the hair-tuft at the proximal angle is yellowish. Brazil (Paraná).
- obsoleta*. **E. obsoleta** *Burm.* (20 c) is above blackish-brownish, on the wings with deeper blackish-brown veins. Palpal base, hips and venter light rosy. The hairy cover at the proximal angle of the ♂ hindwing is beneath yellowish. Expanse of wings: 32 mm. Argentina.
- moloneyi*. **E. moloneyi** *Druce* (20 d). The ♂ has no extended proximal angle of the hindwing, but instead, the posterior femora and tibiae on the inside exhibit long white hair-tufts, whereby it is easily distinguished from all the other species. Blackish-brown, with metallic bluish-green spots on the forehead, vertex, collar, shoulder-covers, and thorax, and small carmine spots on the sides of the collar behind the eyes and at the palpal base. Forehips white. Abdomen laterally, on the last 4 rings also dorsally spotted green. Underneath the 2nd to 4th rings are white. Hindwings in the basal part whitish hyaline, distally blackish-brown. Expanse of wings: 38 mm. British Honduras.
- sixola*. **E. sixola** *Schaus*. Head and thorax brownish-black; palpi at the base, hips at the base and end spotted white, forehips of the ♂ white, in the ♀ striped pink. Collar dorsally and laterally spotted red. Abdomen bluish-black, underneath with 2 rows of white spots. Forewings blackish-brown with darker veins and a faded dark shade before the margin. Hindwings black; in the cell a short white stripe, at the base of the proximal margin a large white spot; behind the cell small whitish spots between the upper median and middle radial vein. Expanse of wings: 34—37 mm. Costa Rica.

E. demonis *Druce* (20 d). Body blackish-brown; on the hindhead, on the dorsum of the first segment and at the sides of the fourth segment carmine spots. The brown forewings with black veins are spotted darker brown in the cell, before the proximal angle and before the apex, and exhibit hyaline spots in the cell-end and behind the cell between the upper median and 4th subcostal vein. The hyaline hindwings are broadly margined by black. Panama (Chiriqui; Lino). *demonis*.

E. littoralis *Rothsch.* Greyish-brown, the head with a blue lustre, the palpi and thorax with a bluish-green opalescence, the abdomen laterally with a slight green lustre. Legs greyish-brown, only the hips and the outside of the tibiae with a green lustre; antennae black. Forewings purple-brown; hindwings greyish-brown with a blue lustre, in the disc lighter and diaphanous, the proximal angle long-stretched. In the ♀ the hindwings are normal, darker brown, without any blue lustre. Length of forewings: ♂ 19 mm, ♀ 17 mm. Venezuela. *littoralis*.

E. scintillans *Rothsch.* (20 d). Most similar to the preceding species, from which it differs by a much more intense and more extensive metallic bluish-green on a darker ground, the colour of the body being here more blackish-brown, the abdomen above of a deep black with a purple lustre, laterally metallic bluish-green, the forewings darker, with a more purple-blue lustre, the hindwings blackish-grey, not greyish-brown. All the legs with a green lustre, the hips of an intense metallic bluish-green, antennae deep purple. Venezuela, Guiana, Amazon. *scintillans*.

90. Genus: **Androcharta** *Fldr.*

It contains well marked species of more than medium size, with very broad forewings; the distal margin is almost as long as the costal margin, the proximal margin very short. The hindwings are very small, in the ♂ pointed and peculiarly distorted and somewhat basin-shaped, the proximal angle drawn forth to an isolated, small lobule; the veins strongly curved and near each other.

A. rubricincta *Burm.* (= *leechi* *Druce*) (20 e) has the abdomen above curled red and black, large white spots on the shoulder-covers, small metallic blue dots on the head, collar, bases of wings, metathorax, and on the black abdominal rings. The brown forewings exhibit 4 small, white spots, the brownish hindwings show a broad, white marginal part. Brazil (Amazon, Sa. Cruz), Argentina. *rubricincta*.

A. meones *Cr.* (= *compta* *Sepp*, *mconioides* *H.-Schäff.*) (20 e) differs from *diversipennis* by large, white spots on the shoulders, and the hyaline spots behind the cell are mostly larger. Colombia, Amazon, Venezuela, Surinam. *meones*.

A. giganteum *Druce* is twice as large as *meones* which it otherwise greatly resembles. The hindwings of the ♂ are silvery white, without the black margin, also longer and more pointed. Both sexes are without the red median band across the abdomen. Rio Napo. *giganteum*.

A. klagesi *Rothsch.* differs from *meones* by its smaller size, light liver-coloured forewings and much smaller hyaline spots. Hindwings yellowish. Length of forewings: 18 to 19 mm. *ROTHSCHILD* considers this animal to be a good species, because it flies together with *meones* at the same places. Venezuela, in December and January. *klagesi*.

A. cassotis *Druce* (20 d). Black; forehead, collar, metathorax and legs spotted metallic blue; abdomen subdorsally and sublaterally with series of blue spots. The black forewings exhibit blue dots at the base and at the cell-angles; red stripes are subcostally, in the cell-end, in the submedian space and at the proximal margin. Behind the cell there is a broad, orange-yellow oblique band from the proximal margin to the 1st median vein. Hindwings in the ♂ grey, at the proximal margin black, in the ♀ with a carmine spot behind the cell; the ♀ is without the red cellular stripes of the forewing. Expanse of wings: ♂ 44 mm, ♀ 56 mm. Ecuador, Amazon. *cassotis*.

A. diversipennis *Wkr.* (= *parvipennis* *Btlr.*) (20 e). The blackish-brown abdomen exhibits carmine dorsal spots (in the ♂ only on the two first segments), as well as subdorsal rows of large, metallic blue spots, and sublateral red spots on the 3 first segments. On the forewing there is beside the large hyaline spot behind the cell in the ♀ a round hyaline spot below the middle of the cell which is absent in the ♂. Hindwing in the ♂ white, in the ♀ with a broad, blackish-brown border. Venezuela, Brazil, Peru. — The species varies considerably. In ab. **brasiliensis** *Btlr.* the ♀ is without the hyaline spot above the middle radial. — **claripennis** *Btlr.* is a male form with 2 small hyaline spots below the cell behind the red stripes. — **obsolescens** *form. nov.* (= ab. 3 *Hmps.*) is without any red stripes at all on the wings; on the abdomen, the ♂ is without any sublateral red spots, the ♀ has only two red dorsal spots. *diversipennis*, *brasiliensis*, *claripennis*, *obsolescens*.

A. stretchi *Btlr.* (20 f) has quite black forewings with a cuneiform hyaline spot in the cell being all filled up with a metallic blue, an oblique whitish spot below it, which turns into a white hyaline spot in the *stretchi*.

♀, and a large, transparent postdiscal band; the hindwings are white, in the ♀ in the middle hyaline. The body is black, with metallic blue spots. Amazon, Peru. — In *hampsoni* subsp. nov. (= subsp. 1 *Hmps.*) there appear on the forewing carmine stripes at the costal margin as far as behind the middle and below the base of the cell; the spot below the middle of the cell is absent; the 3 first abdominal segments show lateral red spots. Uruguay.

hoffmannsi. **A. hoffmannsi** Rothsch. The body is black, with metallic blue spots on the head, thorax, and sides of the abdomen; the latter exhibits a large carmine spot on the 2 first segments. Legs dark brown. Forewings black, with blue spots at the base and a large blue discal spot; above the inner-marginal vein there is a white diaphanous spot, 3 smaller ones between the upper median and middle radial vein. Hindwings in the disc white, broadly bordered with greyish-brown, in the ♀ with black. Length of forewings: 22 to 24 mm. Brazil (Rio Madeira).

91. Genus: **Proctocopis** gen. nov.

Siphon well developed; palpi rather feeble, not projecting beyond the forehead, stretched forward, the terminal joint a little downward, long-haired. Head, thorax and first abdominal segment densely and moderately long haired; abdomen smoothly scaled, the anal segment with a short hair-tuft from the sides of which the uncommonly long valves project. The shaft of the antennae beyond the middle only slightly thickened, above scaled, in the ♂ moderately long serrated. On the long forewings the median veins rise separated afar from the lower cell-end, from which the lower radial veins rise in common, the upper one from a little below the upper cell-corner, the 4 lower subcostal veins in common, the uppermost from the cell. On the hindwings the lower median vein rises far from the lower cell-corner, which sends forth the upper one; the middle radial vein rises above it, the lower one is absent; the uppermost radial and the subcostal vein rise from the upper cell-corner. — Type: *P. forficula* Draudt.

forficula. **P. forficula** spec. nov. (20 f). The only species of this most peculiar genus in its exterior resembles on the whole the larger *Poliopastea*-species, though it differs greatly by the veins. The body is black; a stripe behind the eyes, a spot on the prothorax and on the shoulders, as well as the hips and inner parts of the hind femora are white, a spot at the sides of the prothorax more yellowish. The abdomen shows above broad, metallic bluish-green transverse bands, the naked angular indentations are yellowish. The first segment exhibits a dorsal white spot, the 4 first segments lateral ones; the venter is white. The slender, bent, unsymmetrical clasping-organs of about 5 mm length are lustrous black, on the inside thinly haired and in the middle with a tooth-like projection. The legs are black, outside with a metallic bluish-green lustre. Palpi and antennae black. All the wings above blackish-brown with a bronze lustre; at the articulation of the forewing there is a white spot, two more, smaller ones at the base above the subcostal and below the median; the basal third of the costal space is yellowish hyaline; the submedian space as far as the lower radial is sparsely strewn with brass-coloured scales. The hindwings are of a purer blackish and exhibit, in the inner-marginal area, a large, round, whitish hyaline spot; the costal part above in the basal half white. Beneath the forewings exhibit a metallic green lustre in the disc as far as the submedian fold, in the hindwing in the costal area. — Described according to a ♂ from West Colombia (Rio Aguaca Valley, 2000 m). Type in the Coll. FASSL.

92. Genus: **Eriphioides** Kirby.

This genus and the 3 following ones are very closely allied to each other in the exterior. The abdomen shows at the end lateral hair-tufts, in contrast with the others. The palpi are porrect. The costal margin of the hindwing is bent very much convex and on the forewing it covers the under surface of the proximal margin being covered with silk-like scaly hair.

tractipennis. **E. tractipennis** Btlr. (26 m) differs from the following, similar species by the white base of the palpi, the carmine hindhead and carmine spots on the shoulders. Forewings dark red-brown with black veins. Like in the following species, the rounded costal-marginal part of the hindwing above and the proximal margin of the forewing beneath, covering it, are whitish. Common from Honduras as far as Brazil.

viridis. **E. viridis** Lathy is immediately discernible from the other species by the metallic coppery green basal half of the forewing and the sublateral rows of white spots along the whole abdomen. The hindhead does not exhibit any red spots. Ecuador.

ecuadoriensis. **E. ecuadoriensis** spec. nov. (20 f) is greatly distinguished by the metallic blue colour of the wings and by the abdomen being very much white-spotted. Head, palpi and antennae black, the forehead metallic green, neck red; collar and shoulders white, of a greenish golden iridescence; shoulder-covers and mesothorax striped in a brassy colour; hips white, legs black, with a bluish-green lustre. The abdomen is metallic bluish-

green, above with a golden coppery lustre; the first segment exhibits above in the middle a large, square, white spot of a turquoise-blue iridescence, the lateral tubercles are white; the second ring is all white with a more or less intense brassy lustre; the 4 first rings are ventrally white. The forewings exhibit a blue lustre in the basal halves, distally more green; hindwings in the costal halves brownish-grey, otherwise black, with a bluish-green lustre. Beneath all the wings are bluish-green. Described according to 3 ♂♂ from Ecuador. Type in the Coll. SEITZ.

E. surinamensis Möschl. (= *tractipennis* Druce) (20 f) has unicolorously brown forewings. The abdomen shows dorsal and subdorsal series of copper-coloured spots with a metallic bluish-green lustre. Neck and prothorax spotted carmine. Forehips spotted white. The first 4 abdominal rings show sublateral white spots. Mexico; Panama; Colombia; Surinam. *surinamensis*.

E. phaeoptera Dogn. is allied to the preceding. Black; collar with 2 large, green spots; a similar spot near the base of the forewing; thorax metallic green, abdomen with 3 rows of green spots, beneath blackish-green with 2 white sublateral spots on the two first segments and a white dot on the 4th segment. Hips white. Wings above black with a bottle-green tint. Expanse of wings: 41 mm. Colombia (Cañon del Tolima, 1700 m). *phaeoptera*.

E. rosenbergi Rothsch. greatly resembles *surinamensis*, but it is of much brighter colours, chestnut-brown; the spots on the abdomen are of a coppery green, not bluish-green lustre. It forms about the intermediary between the preceding and *ustulata*. Colombia. *rosenbergi*.

E. ustulata Fldr. (20 f) differs from the preceding by the abdomen being also laterally and underneath metallic green with a coppery lustre, the sides of the second segment exhibiting a white spot and the 3 first rings broad, white sublateral stripes, whilst the 4th ring remains green; the antennae are of a deep metallic blue, on the shoulders there is a carmine spot. The forewings are yellowish-brown with darker veins, towards the margins darkened; the costal part of the black hindwings is whitish. On the under surface the disc of the forewing and the costal part of the hindwing are metallic green. Colombia. *ustulata*.

E. albipunctata Lathy (20 g) differs from all the other species by two very small, oblong hyaline spots of the forewing, one being near the lower cell-end, the other just below it between the median veins; there is often yet a third below the 3rd radial; for the rest the black wings are metallic green at the costal margin and in the submedian area, the hindwings are brownish-white in the costal area. The black body is spotted white on the collar, shoulders and thorax; the bronze-green abdomen exhibits large white lateral spots on the two first rings, white sublateral spots on the 5 first segments. Ecuador. *albipunctata*.

93. Genus: **Ceramidia** Btlr.

Chiefly distinguished from the preceding genus by the absence of the lateral hair-tufts at the anus and the shorter, somewhat erect palpi. Besides the ♂ exhibits scent-scales on the undersurface of the costal margin, the costa of the hindwing being strongly bent here also covers hair-tufts of the forewing. Of late a great number of new species has been described, all of which are very similar, so that it is not easy to discern them.

C. mathani Rothsch. Head and thorax of a bright coppery green, the forehead and thorax yellowish white, the antennae blackish-blue; legs coppery green; neck spotted carmine, shoulder-covers broadly bordered with black. The abdomen is above coppery green, beneath white. Forewings oily deep olive-brown, at the base and the basal third of the costa with a green lustre. Hindwing in the costal half light grey, otherwise brownish-black. Length of forewings: 20 mm. Amazon (Teffé). *mathani*.

C. obscura Btlr. (20 g) is well marked by an entirely white ventral side of the abdomen except the last, black segment. Neck spotted red, basal joints of the palpi and hips white; in the ♂ almost the whole palpi and the forehead are white. The wings are dark-brown with a coppery lustre. On the under surface the inner-marginal area of the fore- and hindwings of the ♂ are white. Amazon. *obscura*.

C. butleri Möschl. (= *eriphia* Druce) (20 g) is white on the ventral side of the 3 first abdominal segments, otherwise copper-coloured. In the neck there is laterally a carmine spot. The black forewings with a slight coppery lustre are metallic green in the basal halves. The greyish-black hindwings have a whitish costal-marginal area. Guatemala, Panama, Ecuador, Surinam, Pará. — **viridis** Druce (20 g) is probably only to be considered as a form of the preceding with a much more intense and more extensive green metallic lustre, more yellowish-red spots in the neck, and mostly of a larger size. From Panama. *butleri*.

- caurensis*. **C. caurensis** Klages (20 g) greatly approximates the preceding, and the 3 first ventral segments are likewise white. The red spots in the neck are indistinct, the green metallic colour of the body is much darker and more subdued, the basal part of the forewing is hardly noticeably greener than the other part of the wing. On the hindwings, beside the white costal area also the median vein is of a white colour. The antennae are metallie dark blue. Forehead and palpi are all black. Venezuela, French Guiana.
- cyanopasta*. **C. cyanopasta** Dogn. is black on the body and wings, with a metallic bluish-green lustre; in the neck 2 red spots. Hips and anterior ventral half in the ♀ spotted white, in the ♂ all white. In the ♂ there are besides white dots on the forehead, shoulders, and subdorsally on the 1st abdominal ring. Expanse of wings: 37—39 mm. Venezuela.
- painei*. **C. painei** Rothsch. Head black, collar snow-white; the thorax and abdomen coppery green; legs and antennae brown; shoulder-covers black. The abdomen exhibits on the 2nd and 3rd rings lateral white spots. The forewing is in the larger proximal half golden green, in the marginal area blackish-green. Hindwings black with a dark grey costal area. Length of forewings: 24 mm. Cauca Valley.
- caca*. **C. caca** Hbn. (20 h) is distinguished by sublateral white spots only on the first abdominal segment in the ♂, on the 3 first segments in the ♀; it differs from the following by the wings being metallie green, not blue, the palpi and forehips exhibiting small white spots; the second abdominal segment is also laterally spotted white. South Brazil and Argentina.
- ornata*. **C. ornata** Druce (20 h) is one of the largest species distinguished from the preceding by the peacock-blue forewings, as well as by the entirely black palpi and hips, though it is otherwise very much allied to it. The golden green abdomen exhibits white spots subdorsally on the second segment and also sublaterally from the second to fourth segments. Colombia, Ecuador, Bolivia.
- scintillo-collaris*. **C. scintillo-collaris** Rothsch. Vertex and collar are lustrous steel-green, forehead white, antennae steel-blue, thorax coppery, on the shoulders white spots, shoulder-covers bordered with black. The first abdominal ring is coppery, laterally white; the rest of the abdomen is brown with a coppery lustre. Forewings dark olive-green, hindwings black with a grey costal area. Length of forewings: 21 mm. Nicaragua.
- phaiodes*. **C. phaiodes** Dogn. ♂. Black; middle of forehead white, collar with two white dots, at the base of the forewing a white spot, thorax with 3 white dots; the first abdominal segment with three white spots, abdomen above yellowish-green metallie with some black dots, each segment bordered with black, the second segment with a pair of sublateral white spots, venter blackish-green, metallie, with a series of white spots; hips white. Forewings black with a green tint and some metallie green atoms and two oval hyaline spots, one of which is behind the median near the base of vein 2, the other opposite in the cell. Hindwings above blackish-green with a large, hyaline submedian spot, the anterior half of the abdominal margin being white. Fringes of the same colour. 44 mm. Colombia, Cañon del Tolima, 2000 m, in October.
- euprea*. **C. euprea** Schaus (20 h). Forewings black, in the apical part somewhat lighter, at the base a metallie green spot. Hindwings likewise black, costal margin broad, light brownish-grey, at the proximal margin two transparent, oblong spots. Forehead, antennae, collar, and a spot on the shoulder are metallie green. Mesothorax brass-coloured, like the abdomen which exhibits an intense coppery lustre particularly towards the apex. On each side of the first segment a spot being white, like the ventral valve in the ♂. Mexico (Misantla), taken in March.
- bricenoi*. **C. bricenoi** Rothsch. Head black, spotted steel-blue; antennae and legs steel-blue. Thorax black with coppery spots. Abdomen coppery with black subdorsal spots, a green dorsal spot and white lateral spots on the 1st segment. Forewing in the basal half golden green, distally deep oil-green. Hindwing brownish-black, in the costal half dark grey. Length of forewings: 25 mm. Venezuela.
- cataleuca*. **C. cataleuca** Btlr. (20 h) is recognizable by the hindwings being white beneath, only one spot at the base of the costal margin being green and one spot at the margin being brown. The green abdomen with a coppery lustre shows broad, white sublateral stripes. In the neck and at the prothorax carmine spots. Ecuador, Surinam, Amazon.
- phemonoides*. **C. phemonoides** Möschl. (= fusiformis Btlr.) (20 i) is easily distinguished by the broad and long white discal stripe on the hindwing beneath; above the wings are dark brown with a coppery lustre. Palpal base and forehead are white, neck and shoulders spotted red. The coppery green abdomen exhibits broad, sublateral, white stripes except the last segment. The legs are striped white. Venezuela, Guiana, Amazon.
- fumipennis*. **C. fumipennis** Wkr. (20 h) is a smaller, dull coppery brown species; forehead and first palpal joint spotted white, neck laterally spotted red; legs striped white. The coppery green abdomen shows white sublateral stripes except the last segment. The under surface of the hindwings differs from the similar species by a slight, white brightening in the cell-end. Amazon.

C. chalcoviridis *Hmps.* Black; palpal base spotted white; in the neck carmine spots. The body is suffused with a brownish-green. The abdomen, except the last rings, shows white sublateral stripes. Hindwing blackish-brown, in the costal area lighter. Expanse of wings: 42 mm. Brazil (Minas Geraes). *chalcoviridis.*

C. flammea *Dogn.* (20 i) has a very intense blue metallic lustre on the forewings, warming more or less into a purple violet in the basal part; at the base of the costal margin there is a small, bluish-green spot. Head and thorax are spotted light golden green like the abdomen; the first 4 segments show white sublateral stripes. Base of collar spotted red. The black underside likewise exhibits a blue lustre. Colombia, Ecuador and Bolivia. *flammea.*

C. chloroplegia *Druce* (20 i) has a black anterior body, the collar being spotted metallic green, and a metallic green abdomen, on which two subdorsal, black, longitudinal stripes are running through; the black ventral side shows sublateral, white, longitudinal stripes. The wings are black with a dark green lustre. The under surface is black except the grey inner-marginal area of the forewing; the discal area of the forewing and the costal area of the hindwing are suffused with a metallic green. Venezuela, French Guiana. *chloroplegia.*

C. affinis *Rothsch.* Head and thorax black with lustrous bluish-green spots; neck red; collar metallic bluish-green. Abdomen coppery green with black, subdorsal, and yellowish-white lateral stripes. Forewings steel-blue, in the basal third greenish. Hindwings dark brown, in the costal half grey. Length of forewings: 17 mm. Amazon (Teffé). *affinis.*

C. viridisaturata *Rothsch.* Head and antennae black with greenish-blue spots; thorax and abdomen of a brilliant coppery colour, collar metallic greenish-blue. The forewing is black in the basal fifth, in the 2 middle fifths golden green, in the distal two fifths of a deep olive-green. Hindwings black, in the larger costal half yellowish-grey. Length of forewings: 23 mm. Probably from Rio. *viridisaturata.*

C. underwoodi *Rothsch.* The head is black with a red neck and steel-blue antennae, thorax and abdomen are coppery olive, the 1st segment metallic green. Forewings deep olive-green, the disc is traversed by an indistinct metallic green band. Hindwings greenish black, the costal area chestnut-brown. Length of forewings: 20 mm. Costa Rica. *underwoodi.*

C. simplex *Rothsch.* Head and thorax are brown, with coppery spots, the neck carmine, chest white, abdomen black, with dorsal and lateral coppery bands. Forewing purple brown. Hindwing dark brown, in the costal half brownish-grey. The ♀ is a little paler and more monotonously brown. Length of forewings: 18 mm. From Ecuador and Colombia. *simplex.*

C. klagesi *Rothsch.* is of a deep olive-green on the body and forewings; neck carmine; antennae deep steel-blue; chest white. Hindwing olive-green, in the costal half silvery grey. Length of forewings: 18 mm. Surinam, taken in February. *klagesi.*

C. musicola *Cockerell* seems to be allied to *butleri* (20 g). Body like there, only with more white spots, for instance on the shoulder-covers, forehead and sides of the head. Forewings above unicolorously bluish-black, faintly metallic. The costal-marginal half of the hindwing lustrous whitish. Under surface of a more intense metallic lustre than above. Expanse of wings: 37 mm. It was found in banana shipments in Colorado, and has undoubtedly been imported from Central America. *musicola.*

94. Genus: **Amycles** *H.-Schäff.*

This genus containing but few species is very closely allied to *Ceramidia* and only differs by the course of the lowest subcostal vein on the forewing, rising here only close before the apex, and by the middle radial of the hindwing rising more from the middle of the discocellular.

A. anthracina *Wkr.* (20 i). Blackish-brown, antennae at the tips white, in the neck two red dots. The first abdominal segment shows a white spot on each side. The dark colour of the forewings turns lighter to a reddish-brown before the yellowish-white apical spot. The apex itself is narrowly dark-brown in the ♀, hyaline diaphanous in the ♂. The dark hindwing shows two hyaline stripes at the proximal margin, the costal margin being whitish. Distributed from Mexico through Central America as far as Brazil. *anthracina.*

A. adusta *Fldr.* (20 i) is on an average larger than *anthracina*, and the light, brownish apical spot of the forewing is much more broadly margined by black, so that it makes the impression of a subapical oblique band. The shape of the wings is comparatively more extended, and the small hyaline stripes at the base of the hindwing are, particularly in the ♂, narrower and shorter. Length of forewings: 21 to 22 mm. Mexico. *adusta.*

A. affinis *Rothsch.* (20 k) differs from the preceding by its smaller size and decidedly broader shape of the wings, as well as by the much more extensive hyaline spot occupying the whole apical third and being defined from the dark ground of the wings by a concave band being proximally reddish-brown, distally cream-coloured. The inner-marginal area of the hindwing is more extensively hyaline. Length of

forewings: 14 to 15 mm. This species, having been described from Venezuela and Nicaragua, is before me also from Mexico.

- tenebrosa.* **A. tenebrosa** *Rothsch.* is jet-black on the body. The forewing is of a deep blackish-brown in the basal two thirds, the apical third being light brown, somewhat more thinly scaled. Hindwings blackish-brown. Length of forewings: 17 mm. Venezuela.
- brinkleyi.* **A. brinkleyi** *Rothsch.* is unicolorously deep brownish-black, only in the apical third of the forewing somewhat lighter. Length of forewings: 17 mm. Cauca Valley.
- dolosa.* **A. dolosa** *Wkr.* (20 i) is of a dark brown ground-colour on the body and wings. Neck laterally spotted carmine. The abdomen shows dorsal and lateral coppery-green stripes and, on the 2 first rings, sublateral white spots. Brazil.
- klagesi.* **A. klagesi** *Rothsch.* is larger than the preceding and distinguished by the greater extent of the metallic colour being here more bluish-green, which is noticed not only on the abdomen but also on the head and collar. Antennae steel-blue; chest white. The ♀ is much more feebly marked green. Length of forewings: 15 to 17 mm. Venezuela.

95. Genus: **Antichloris** *Hbn.*

Like the preceding genera, but whereas there the lower median vein of the hindwing rises together with the upper one from the lower cell-corner, it here rises distinctly below it.

- quadricolor.* **A. quadricolor** *Wkr.* (20 k) greatly differs from all the species by the deep metallic blue colour, orange-yellow fringes of the forewings and a triangular carmine spot in the middle of the margin of the black hindwings with red fringes. Expanse of wings: 36 mm. Jamaica.
- puriscal.* **A. puriscal** *Schaus.* Head, collar and shaft of antennae dark green, in the neck at the sides 2 red small spots. Thorax black, shoulder-covers striped green. Abdomen black, the 1st segment above bluish-green, with green dorsal and lateral stripes, sublaterally with white lines. Forehips white. Forewing velvety black with a white apex and green stripes at the base of the subcosta and submedian. Hindwing in the costal area of a silky-lustrous greyish-white. Expanse of wings: 36 mm. Costa Rica.
- trinitatis.* **A. trinitatis** *Rothsch.* Head and collar metallic blue, tips of antennae white; thorax blackish-brown, spotted bluish-green. Abdomen coppery green, with subdorsal blackish-brown stripes. Wings sooty blackish-brown. Length of forewings: 18 mm. Trinidad.
- metallica.* **A. metallica** *Rothsch.* Head and thorax black, the latter spotted coppery; abdomen coppery golden, the 1st segment metallic green; on the underside there are white sublateral stripes. Forewing in the basal half metallic golden green, in the ♀ bluish, distally black. Hindwing blackish-brown, costal half grey. Length of forewing: 18 to 19 mm. Ecuador.
- intensa.* **A. intensa** *Rothsch.* Head and collar black, with metallic bluish-green spots, thorax blackish-brown; abdomen coppery golden, with broad black subdorsal stripes; on the chest 2 white spots; legs dark brown. The forewings are blackish chocolate-brown with an oily lustre. Hindwings blackish-brown, in the costal area grey. Length of forewings: 22 mm. Surinam.
- eriphia.* **A. eriphia** *F.* (= *alceton* *Cram.*, *phemonoe* *Hbn.*, *melanochloros* *Sepp.*, *scapularis* *H.-Schäff.*, *helus* *H.-Schäff.*) (20 k) is black with a deep green bronze lustre; in the neck two red dots. The abdomen shows somewhat lighter green dorsal and lateral stripes; on the 2nd segment laterally a white dot; sublateral white stripes. The costal-marginal area of the hindwing is light brownish-grey in the ♂. From Venezuela to Paraguay and in Trinidad.
- nigrolineata.* **A. nigrolineata** *Rothsch.* (20 k) is at once discernible from *eriphia* by its broad, jet-black subdorsal stripes on the coppery abdomen. Head and spots on the black thorax are metallic green. Length of forewings: 20 mm. Venezuela.
- scudderi.* **A. scudderi** *Btlr.* (20 k) differs from *eriphia* by its deep blue ground-colour with a purple lustre. From Pará.
- atrinervis.* **A. atrinervis** *Rothsch.* Very near to *scudderi*. Head and thorax are velvety bluish-black, with lustrous bluish-green spots; neck carmine. Abdomen black with dorsal and lateral coppery green stripes; sublaterally there are broad white bands, and the 3rd ring shows white lateral spots. The forewings are bronze-green in the basal two thirds, in the marginal third deep oily greenish-blue with black veins. Hindwing in the larger costal area grey, otherwise blackish-brown. Expanse of wings: 20 mm. Amazon (Teffé). — subsp. **steinbachi** *Rothsch.* is of a lighter and more brilliant green on the forewings, and the hindwings are of a pure black. Bolivia.
- purpurea.* **A. purpurea** *Lathy.* according to the description, seems to be allied to *Eriphioides ecuadoriensis* having been described above, which, however, according to the neurulation, is certainly no *Antichloris*, and likewise

greatly approximates *scudderi* and is easily distinguishable from it by white dorsal spots on the 2 first abdominal rings; the first 4 rings are underneath all white. The spots on the head and thorax are more metallic green. Ecuador.

A. quartzi Klages (21 a) looks very much like *eriphia* (20 k), but it differs somewhat in the veins, *quartz*i. the discocellular being more strongly flawed and the subcostal and uppermost radial vein rising from the upper cell-corner. Palpi outside white. On the collar and shoulders blue or green spots, of the same colours are stripes on the thorax and shoulder-covers. All the rest like in *eriphia*. Venezuela.

A. panacea Druce (21 a) is dull coppery-brown, on the shoulders spotted carmine. Forehips and *panacea*. abdomen above metallic blue. Hindwings in the ♂ dirty white with a blackish-brown marginal band, in the ♀ blackish-brown. Costa Rica.

96. Genus: **Methysia** Btlr.

The few little species are greatly distinguished by an extensive area of soft, silvery white scales, extending on the under surface of the forewing from the submedian fold to the proximal margin, the inner-marginal vein exhibiting besides an oblong spot of hairy scales; the corresponding costal area above on the hindwing being somewhat stunted, is covered by it and likewise scaled white. The veins of the forewings do not show any peculiarities; on the hindwings the median veins rise from the same spot below the lower cell-corner, the lower radial from the middle close before the margin, the upper one and the subcostal stand on a long pedicle. Abdomen somewhat strangulated at the 2nd segment.

M. hilda Druce. Head, abdomen and legs are black. Collar, thorax, and the first abdominal rings *hilda*. are of a brilliant scarlet. Wings semi-diaphanous blackish with black veins and margins. Expanse of wings: 26 mm. South East Peru.

M. notabilis Wkr. (21 a) has an orange-brown thorax, the rest of the body inclusive of the shoulder- *notabilis*. covers is black, the ventral side and the greater part of the legs white. The forewings are hyaline with black margins, particularly the proximal margin as far as the submedian fold are broadly black; hindwingcostal-wards from the median vein silvery white, below it black. Distributed from Guiana to the Amazon.

M. melanota Hmps. (21 a). Exactly like the preceding, but with an entirely black thorax; the white *melanota*. base of the collar and front of the palpi certainly characterize the insect as a distinct species. British and French Guiana.

97. Genus: **Pseudaclytia** Btlr.

The few, rather insignificant species, have the abdomen roughly haired at the base. On the forewings the lower radial veins rise from the lower cell-angle, the upper one from below the upper cell-corner. On the hindwing the lower radial veins stand on a long pedicle, by which the genus is easily recognized.

P. umbrica Druce (21 a). The anterior body is ochreous brownish, in the neck yellow, the abdomen *umbrica*. orange-yellow with broad, black dorsal spots, the venter whitish. Forewings brownish with darker veins. Hindwings blackish-brownish with a lighter costal area. Expanse of wings: 28 mm. Brazil.

P. flavidorsia Hmps. Head, chest, legs and abdomen as well as the distal margins of the shoulder-*flavidorsia*. covers are black, the vertex and thorax orange. Forehips spotted white. Forewings grey, with black veins and in the marginal area internerval stripes, with a broadly black-dusted proximal margin. Hindwings hyaline with black veins, margins, and a grey costal area. Expanse of wings: 16 mm. Venezuela.

P. opponens Wkr. (= *rufogularis* Möschl.) (21 b). Blackish-brown with an orange-brown neck and *opponens*. collar; forehead and palpi striped grey; forehips white; abdomen with a blue lustre, underneath greyish-white. The hindwings are hyaline with a broad black border, the inner-marginal area hyaline. Guiana to the Amazon.

P. minor Schaus (21 b) differs from *opponens* by its much smaller size and deeper black colouring; *minor*. the black collar is at the extremest base orange like the neck; the best distinguishing mark is the broad black proximal margin of the hindwing. French Guiana.

P. major Druce has a brownish black body; hindhead laterally orange. Forewings brownish-black, *major*. at the margin paler, with black veins. Hindwings hyaline, apex and distal margin dusted with black, veins black. Expanse of wings: 40 mm. Peru.

P. unimacula Schaus resembles a small *Desmotricha*. Body above black, beneath brownish, abdomen *unimacula*. striped grey. Forewings black with a broad, yellow, postcellular band from the costa to the lower median vein at the distal margin. Expanse of wings: 34 mm. French Guiana (Cayenne).

98. Genus: **Atyphopsis** Btlr.

The surest distinguishing marks are the lower radial veins rising petiolated on the fore- and hindwings. The upper radial rises on the hindwings far below the upper cell-angle. The abdomen exhibits a rough hairing at the base and lateral tubercles at the first segment.

modesta. **A. modesta** Btlr. (21 b). Head black; hindhead, collar, foremost prothorax, and the middle abdominal rings are orange; the thorax and two first segments grey, the two last ones black. Wings very thinly scaled, yellowish-grey with darker veins. Guiana to the Amazon.

roseiceps. **A. roseiceps** Druce (21 b). Like *modesta*, but the body is darker greyish-brown, and the hindhead, spots on the shoulders, and the middle abdominal rings are rosy red. Brazil (Rio de Janeiro, Santos).

obscura. **A. obscura** Hmps. (21 b) is quite unicolorously brownish, on the hindhead and anus somewhat more yellowish. Darker brownish spots are in the middle of the cell and at the transverse vein, an indistinct oblique band being interrupted on the lower radial vein is behind the cell, and one before the margin. The hindwings are very thinly scaled in the disc. From Brazil (Rio Grande do Sul).

99. Genus: **Anaphlebia** Fldr.

Only one small species which greatly reminds us of *Teucer albapex* (19 l) by the long and pointedly extended anal angle of the hindwing in the ♂. On the forewings the lower radial veins are petiolate, the upper one rises from the upper cell-corner, the 1st subcostal vein from the cell. On the hindwings the 1st median vein and the lower radial veins proceed from the same place and are thickly scaled on the under surface; the costal vein is present as a rudiment. In the ♀ the anal angle is not extended and the veins of the hindwings are quite different, the 1st median vein being absent, and the lower radial veins rising on long pedicles; the scaling of these veins on the under surface is of course likewise absent.

caudatula. **A. caudatula** Fldr. (21 c) has a black body with small white spots on the palpi, forehead, collar, shoulders and forehips. The abdomen shines faintly blue, and exhibits on the first segment subdorsal white spots, on the other rings a whitish median line. The venter of the ♀ is white. The hyaline wings have very broad black margins. The antennae are long-combed in the ♂, in the ♀ short-combed. We figure the ♀ having not been described hitherto, from Pebas; FELDER's type, a ♂, likewise originates from the Amazon.

100. Genus: **Sciopsyche** Btlr.

Only few species with the antennae being particularly in the ♂ remarkably long doubly combed, the serration being very strong, at the ends thickened to clubs and being very dense; the strong shaft of the palpi is thickly covered with scales. The obliquely erect palpi project beyond the head. The wings are long and narrow; on the hindwings the upper median vein rises with the lower radial veins from the same place of the lower cellcorner, on the forewings the upper radial vein rises from below the upper cell-corner, the subcostal vein from the cell.

tropica. **S. tropica** Wkr. (= *cinerea* Btlr.) (21 b). Black, the wings thinly scaled, the hindwings in the disc diaphanous; on the forewing, below the median at the base, there is a metallic bluish-green spot, on the hindwings the veins exhibit a metallic green lustre. The black abdomen exhibits broad, metallic green lateral stripes and white sublateral spots with a green lustre. Distributed from Mexico (Orizaba, Misantla: August to October) through Central America (Honduras, Colombia) as far as Brazil (Amazon, Pará, Espiritu Santo).

remissa. **S. remissa** Dogn. Body pale yellowish, the neck bordered with a darker yellow. Forewings isabel-coloured, veins, cell-end and margins light yellow. Hindwings white, bordered with light yellow. Expanse of wings: 29 to 32 mm. Venezuela.

auranti-cauda. **S. auranticauda** Klages. Head, thorax, legs and the 4 first abdominal rings above are black, the rest of the abdomen and lateral spots on the 4th segment are orange. Forewings very thinly scaled blackish-brown with black veins and very fine margins. Hindwings semi-diaphanous, at the border and innermarginal part more densely and irregularly scaled brownish-black. Expanse of wings: 32 mm. Venezuela. — On account of slight differences of the neurulation, it will later on perhaps be necessary to establish a special genus.

101. Genus: **Napata** Wkr.

About 30 small to medium-sized species, often decorated with very lustrous metallic colours. The smoothly scaled abdomen exhibits a slight elevation at the sides of the base. The lower cell-end of the hindwing is much longer than the upper one; on the long, narrow forewings the upper radial rises from the upper cell-

angle. The palpi are erect, the shaft of the antennae covered with scales of mostly metallic lustre. Some species greatly approximate the genus *Cyanopepla* from which they may be separated by the middle radial of the hindwing rising very close at the upper median and lower radial vein, whilst in *Cyanopepla* it always rises much higher.

N. fenestrata Druce (21 c) is a small species with hyaline spots on the olive brown forewings; the hindwings are hyaline with a black border and an ochreous-yellow haired proximal margin. The olive-brown body exhibits an orange-yellow colour in the neck, on the shoulders, at the sides of the 4th to 6th abdominal rings, and subdorsally on the 5th and 6th. The venter is orange except the last segments. Brazil. *fenestrata.*

N. walkeri Druce (21 c). This most conspicuous animal and the following similar species are quite unlike all the *Syntomidae* known, and it copies, by its marking and colouring, certain species of the *Erycinidae*-genus *Mesene* *, the *Zygaenidae*-genera *Euclimacia* and *Malthaca* **, and the Pyralid *Mapeta xanthomelas*. Orange-yellow, apex of the forewing white with black veins. Palpi, legs and venter spotted white and black. It is found in Mexico (Orizaba, Misantla: February, August to October), as well as in Costa Rica, Panama, and in Trinidad. *walkeri.*

N. atricincta Hmps. resembles the preceding from which it differs by its black costal and proximal margins, black margin of the hindwing, being expanded at the anal angle, black lateral stripes at the abdomen, the ventral side of which is all white, by the almost quite black palpi and the somewhat smaller size. From Bahia. *atricincta.*

N. flammans Dogn. Palpi white with a black terminal joint. Head and collar black with white dots. Thorax light orange, abdomen black, above with orange-yellow, beneath white rings. Forewings in the larger basal halves very pale orange-yellow, distally blackish. Hindwings orange with a marginal series of black spots, which flow together towards the apex. Fringes orange with single black hairs. Expanse of wings: 28 mm. Colombia (Quindiu, 2000 m, in October). *flammans.*

N. atalanta Druce. Head, antennae, thorax and abdomen are black, forehead white. The last abdominal rings banded white. Forewings brownish black, from the base to the middle diaphanous, at the base a small metallic blue spot. Hindwings black. Expanse of wings: 26 mm. Amazon. *atalanta.*

N. hyporhoda Dogn. Black; abdomen above with some metallic blue hairs. Hips metallic blue. Forewings above brownish black. Hindwings above and beneath black with a large subapical and subterminal red spot which, however, does not reach the costal margin. Forewings beneath black with a large postmedian red spot. Fringes black. Expanse of wings: 28 mm. Colombia (Quindiu, 2000 m). *hyporhoda.*

N. felderi Zerny (= eucyane Fldr. pr. p.) (21 c). This largest and most variegated species has black forewings, being metallic blue at the base, with a broad red band right across the middle of the wing and a shorter, narrower one behind it; the hindwings are all black with a blue base. Brazil: Santos. *felderi.*

N. splendida H.-Schäff. (= eucyane Fldr. pr. p., argentiflua Martyn) (21 c) is the easiest discernible from *felderi* by the large, red marginal spot of the hindwing; besides by the palpi and legs being anteriorly striped more intensely white, the size being generally somewhat smaller, the shape of the wings being rounder and the red spots on the forewing placed more obliquely, both of which are red beneath. The extent of the red subapical spot varies, it may extend as far as to the margin: = subsp. **eucyane** Fldr. — In *entomistis* Strand (= ab. 2 Hmps.) the red spot of the hindwing is disappearing or absent altogether. The species is common and widely distributed from Colombia, Venezuela, Guiana to Brazil and Bolivia. *splendida.* *eucyane.* *entomistis.*

N. banghaasi spec. nov. (21 d) is a difficult species which resembles *felderi* almost still more, because it has in common with it the more pointed shape of the wings and the not so oblique position of the somewhat narrower red spots of the forewings. The hindwings are of a more triangular shape owing to the longer proximal margin. On the hindwing there appears near the margin a minute red spot, being beneath larger, between the median veins. The subapical spot of the forewing is white beneath. The palpi are all black like the legs, spotted metallic blue; the white ventral stripe is reduced and leaves the last segments black. — Described according to two pure ♂♂ from Brazil (Sa. Catharina and Joinville, from BANG-HAAS). Perhaps the name *melinda* Dyar must be substituted for it. *banghaasi.*

N. lisita spec. nov. (21 d) is to be separated from the preceding by the much more slender and more stretched shape of the wings, and by the extremely intense blue metallic lustre on the whole body, on the basal half of the forewing and the whole hindwings. The latter are without a red spot; the discal oblique band of the forewing is interrupted by black on the median; the venter is broadly white, like the front of the palpi, the throat, spots on the shoulders, the hips, stripes on the legs, and a spot at the base of the antenna. Beneath the greatest part of the surface of the wings is of an intense greenish-blue, the spots red. — One ♂ from North Ecuador (Baños) from BANG-HAAS. *lisita.*

N. maranhaonis Strd. (27 a) likewise resembles *splendida*, but it is much smaller (expanse of wings: 30 mm). The forewings exhibit only a red transverse band including a yellow blurred spot between the radial veins; the blue longitudinal stripes are narrower, at greater distances from each other, and at the apex with red scales. The red spot of the hindwing is larger and the abdomen exhibits a lighter dorsal line. Described according to 1 ♀ from Brazil (Maranhão). *maranhaonis.*

*) Comp. Vol. V, t. 134—135.

**) Comp. table 9.

- unifascia.* **N. unifascia** *Schaus* (21 c) has a large, red spot in the disc of the forewing, which extends in the cell, extended taperingly, as far as near the base, the submedian area being blue as far as behind the middle. The hindwings are almost entirely blue. The body is black, on the forehead, collar, shoulder-covers, thorax and abdomen metallic blue; the venter striped white. Ecuador.
- abbreviata.* **N. abbreviata** *spec. nov.* (12 d) is probably hardly only a form of the preceding species. It differs above all by a somewhat narrower red oblique spot of the forewing, the continuation of which in the cell is absent. Behind the red spot there are also above 2 metallic greenish-blue spots between the radial veins. On the submedian there is a golden green stripe which greatly contrasts with the metallic blue colour of the inner-marginal base. The hindwings are more violettish-blue. On the under surface of the hindwings, from the base as far as near the margin, there extends below the median a white spot being bordered by a blue iridescence. Hips and outside of the posterior tibiae white. One ♂ from the Rio Songo (Bolivia; A. H. FASSL).
- iridis.* **N. iridis** *Hmps.* (21 d). Body black, with a metallic blue lustre; front of the palpi, legs and venter striped white. The forewing is in the proximal half extensively carmine, the hindwing metallic blue except the black border. Bolivia.
- castra.* **N. castra** *Hmps.* (21 c) exhibits on the blackish-brown forewings an orange-yellow stripe on vein 1 and an orange postdiscal band, which does not reach the costal margin and proximal angle; the base of the costal margin is metallic green, the fringes at the apex and proximal angle are white, on the unicolorously brownish-black hindwings all white. The body is black, with metallic bluish-green spots and stripes. Brazil (Paraná).
- jynx.* **N. jynx** *Hbn.-G.* (26 l) greatly resembles *castra*, the body is of a pure blue, not spotted green, and the orange oblique spot is larger and broader and extends from near the costa to the distal margin and has, on the proximal side, a continuation towards the base below the costa. Expanse of wings: 44 mm. Amazon (Paraná, Sa. Catharina).
- subflaves-cens.* **N. subflavescens** *Kaye.* Body blackish-brown, shoulder-covers anteriorly orange. Forewings brownish-black with a broad ochreous-yellow oblique band through the centre; costal base yellow. Hindwings above brownish-black, beneath light yellow with a broad black marginal band and small blackish stripes in and round the cell. Expanse of wings: 33 mm. British Guiana.
- metamela.* **N. metamela** *Dogn.* Body black, with a faint blue lustre. Palpi beneath yellow; vertex and neck with some yellow hairs. The forewings exhibit a broad yellow oblique band from the middle of the costa to the proximal angle. On the hindwings the end of the median is yellow. Under surface like above, bases of the wings and the veins dusted somewhat whitish. Expanse of wings: 29 mm. French Guiana.
- chalybea.* **N. chalybea** *Hbn.* (21 d) greatly approximates the following from which it differs by the wings being much more extensively suffused with a more radiant bluish-green; the vertex is also bluish-green. Cuba.
- euchloa.* **N. euchloa** *Hmps.* (= *chalybea* *Hmps.*). Body metallic bluish-green. Palpal base, vertex, the last 4 abdominal rings, and a part of the preceding ring orange. The black forewings show metallic bluish-green stripes below the costa, in and behind the cell and shorter ones at the base of the proximal margin. Hindwings metallic bluish-green, towards the margin of a pure blue. Expanse of the wings: 36 mm. Jamaica.
- albiplaga.* **N. albiplaga** *Wkr.* (= *apicalis* *H.-Schäff.*, *lelex* *Druce*) (21 e). The 4 wings are black with white apical spots and, particularly towards the proximal angle, white fringes. The forewings show a long, broad, metallic blue stripe below the median, much smaller ones at the base of the costal margin and at the cell-end. On the under surface, all the wings exhibit very intense lustrous bluish-green spots in the discocellulars with 2 dots each behind them. The front of the palpi, a spot at the antennal base, the forehips, middle and posterior tibiae are white, like the ventral side of the abdomen. Head, collar, mesothorax, shoulder-covers and legs are striped metallic blue. Abdomen with blue dorsal and lateral spots. From Mexico through the whole of Central America as far as Rio de Janeiro.
- quadristri-gata.* **N. quadristrigata** *Hmps.* (21 e) differs from the similar *albiplaga* by 4 metallic blue, small stripes on the forewing behind the cell; the abdomen is also sublaterally spotted blue. From the West Indies (Sa. Lucia; Dominica).
- superba.* **N. superba** *Druce* (21 e) is allied to the preceding species, but easily discernible by the metallic blue colour being extended upon the whole basal halves of both the wings; at the transverse vein 2 blue, small spots; apices of all the wings white. Peru.
- lelex.* **N. lelex** *Druce* (21 e). The black body is spotted metallic blue on the head, collar, shoulders, shoulder-covers, thorax, abdomen and legs, the antennae are of a deep metallic blue. The black forewings are spotted blue at the base of the costa and vein 1, the fringes being white at the apex. The hindwings show a blue lustre and a white apical spot. Distributed from Mexico through the whole of Central America as far as Colombia, Venezuela and Ecuador.

N. pseudolelex *Rothsch.* differs from *lelex* by the absence of the white fringes of the hindwings. Ecuador; *pseudolelex*. Colombia, Venezuela.

N. rhabdonota *Hmps.* (21 e). The body is black, with metallic blue spots and stripes, the palpi, basal joint of the antennae and forehips are white, the venter striped white. The forewings exhibit metallic blue stripes at the base of the costal margin and at the vein 1, the apex and proximal angle being spotted white; fringes of the hindwings at the apex white. Dominica.

N. terminalis *Wkr.* (21 f) differs from the preceding by the white fringes being present only at the extreme apex of the forewing. The ground-colour is a dull greyish-brown, the shoulders show white spots, the disc is very thinly scaled; the fringes of the hindwings are white towards the anal angle, the inner-marginal area beneath being white. Brazil (Pernambuco).

N. leucotelus *Btlr.* (21 f) is one of the smallest, insignificant species. Forewings black with a large, transparent, discal spot, the fringes being white at the apex, and a very small, metallic bluish-green spot at the base. Head, collar, mesothorax, and lateral spots on the abdomen metallic greenish-blue, the abdomen shows above a broad, greenish-brown median stripe. Underside of the palpi, legs, and centre of the venter white. Mexico, Guatemala, Honduras, Costa Rica, Venezuela, Surinam.

N. venezuelensis *Klages.* Blackish-brown. Forehead and front of the palpi white, body spotted blue, hips in the ♂ white. The abdomen shows a whitish dorsal line and lateral metallic blue spots turning more green posteriorly. Underneath the first 6 rings show a broad white middle stripe which may be absent or indistinct in the ♀. Forewings with a fine white costal stripe, at the base metallic blue, with hyaline stripes in and below the cell; fringes at the apex and proximal angle white. Hindwings black, with white fringes towards the proximal angle. Expanse of wings: 25 to 27 mm. Venezuela.

N. albimaculata *Hmps.* (21 f). The very long, narrow, blackish-brown forewings exhibit a white spot behind the cell, the hindwings are white except the margin and costal margin. The first abdominal segment shows subdorsal white spots, the 4th to 7th red spots. The ventral side is for the greatest part white. From Panama and Venezuela.

N. guatemalena *Druce* (21 f). The smallest species with black wings, the fringes being white at the apex. The black body is spotted metallic blue on the forehead, collar, sides of thorax, and legs; vertex, neck, and palpal base scarlet. The abdomen exhibits metallic blue dorsal and lateral lines, on the venter white spots. From Mexico to Guatemala.

N. munda *Wkr.* (21 f) is throughout metallic bluish-green on the body and wings. Palpal base, throat, and vertex carmine. The fringes are white at the apex and proximal angles. Known only from Hayti.

N. lena *Schaus.* Black, on the abdomen with a blue lustre. The basal joint of the palpi, hindhead, neck, and anal tuft are carmine. Sides of forehead, hips and stripes on the legs, as well as a broad ventral stripe are white. — The forewings are white at the basal half of the costal margin, at the apex and ends of the fringes. Expanse of wings: 40 mm. Peru.

N. cincticollis *Fldr.* (21 f) exhibits a square yellow spot in the cell-end of the brown forewings, and another one behind it, the black hindwings show a hyaline stripe below the cell. On the under surface the wings are suffused with a brilliant metallic blue. The anterior body is black, the forehead is laterally white; the hindhead, neck, and spots on the shoulders are carmine; forehips white. The abdomen is above metallic blue, beneath white. Colombia (Bogotá); it lies before me from the Rio Dagua (Coll. FASSL).

N. boettgeri *Druce.* The description of this species, being unknown to me in nature, coincides so completely with that of *Delphyre tetilla* *Dogn.* (= *elegans* *Lathy*) that it may possibly be the same animal; the 3 examples I was able to examine, all belong to *Delphyre*. *boettgeri* was described from Peru.

N. quadrimaculata *Möschl.* (21 f). Body blackish-brown, forehead and hips white; vertex and 1st palpal joint scarlet. Base of the shoulder-covers and of the abdomen metallic green. The black forewings with some green at the base exhibit a large, elliptic, white spot below the cell-end; apex white. Hindwings the same with a white spot below the cell-end, and a white apex, with a green-striped inner-marginal vein. Expanse of wings: 30 mm. Venezuela, Guiana.

N. sanguicincta *Hmps.* Anterior body dull black, abdomen metallic blue; palpal base and hindhead carmine; forehead, collar, thorax, and legs spotted blue. Forewings black with white fringes towards the apex. Hindwings with a blue lustre and a broad, carmine marginal band. Expanse of wings: 32 mm. Peru.

N. flaviceps *Hmps.* Black, suffused with metallic blue. Front of the palpi, forehead, borders of the shoulder-covers, chest and legs, a dorsal, lateral and ventral stripe on the abdomen are white. Femora and shoulder-spots of a brilliant orange. On the hindwings a fine subcostal stripe, a stripe below the base of the

cell, and an oblique band behind the cell with rounded ends between the upper median and lowest subcostal vein are white. Hindwings lustrous blue with a hyaline stripe in and behind the cell, the proximal margin being white. Expanse of wings: 42 mm. Panama.

broadwayi.

N. *broadwayi* *Schaus* (21 g) is distinguished by much shorter palpi not reaching the vertex. The body is black, with bluish-white spots on the forehead, collar, shoulders, and shoulder-covers. Forehips and the 1st joint of the tarsi white; anterior and middle tibiae inside spotted earmine. Metathorax, lateral and dorsal spots on the 1st abdominal ring brassy-green, as well as broad transverse bands on the other rings; underneath there is a large, white ventral spot on the first segments. Wings of a brassy-green lustre; the forewings exhibit hyaline spots in and below the middle of the cell, at the cell-end, 2 behind the cell, and a larger one below the 3rd radial. The hindwings with small hyaline spots at the base of the cell and in the upper cell-angle. Expanse of the wings: 46 mm. Trinidad.

102. Genus: **Trichromia** *Hbn.* (*Patreliura* *Hmps.*)

Distinguished from the preceding genus by long hair-tufts at the sides of the abdomen. On the forewings the upper radial rises below the upper cell-angle, the 2 uppermost subcostal veins rise separately from the cell. On the hindwings the upper median and the 3rd radial stand on a long pedicle; the middle radial rises from above the lower cell-angle.

capys.

T. *capys* *Cr.* (= *lacteinota* *Btlr.*) (21 g) has dark brown forewings with yellowish veins and a white apical spot, hyaline hindwings with greyish-blue veins and margins. The brown body exhibits orange-yellow spots on the head and neck. It flies in British Guiana, Brazil and Bolivia and copies *Episcepsis capysca* and *capysoides*, the differences of which are mentioned there.

103. Genus: **Lymire** *Wkr.*

In the veins rather near the genus *Atyphopsis*, but on the forewings the 1st median vein rises below the lower cell-angle, the upper radial from the upper cell-angle; on the hindwings the two lower radials stand on a longer pedicle; the costal vein is often rudimentarily present. The abdomen is not roughly haired at the base.

metamelas.

L. *metamelas* *Wkr.* (21 g). Body black, hindhead and thorax orange. The thinly scaled forewings are blackish, the hindwings hyaline, the margin and a broad inner-marginal area black. Guiana to the Amazon.

strigivenia.

L. *strigivenia* *Druce* (21 g). Like the preceding, but with a quite unicolorously blackish-brown thorax; forehead, chest, legs, and venter lighter greyish-brown. French Guiana.

melanocephala.

L. *melanocephala* *Wkr.* (21 g) is a large species with a dove-grey body and forewings with a white costal margin; the head is black; palpi, collar, shoulders, throat, hips, and femora yellow. The abdomen is posteriorly bluish-black; the venter and anus yellow. The hindwings are semi-diaphanous, on the veins and border pale brownish. Jamaica.

edwardsi.

L. *edwardsi* *Grote* (21 h) is smaller than the preceding, on the wings somewhat darker brownish grey, the abdomen posteriorly with a bluish-green lustre, beneath whitish; the head is greyish-brown like the other part of the body; palpi, vertex, neck and throat orange. From Florida and the Bahamas. — The grown-up larva is whitish with a red-brown head, a blackish dorsal stripe and orange-yellow subdorsal and lateral lines, with yellow bristly hairs standing on tubercles, on the 4th ring pencils of reddish-brown feathery hairs. It lives on *Ficus pedunculata* and changes in a cocoon interwoven with hair to an immobile, red-brown pupa.

albipennis.

L. *albipennis* *H.-Schäff.* (21 g) copies certain *Lithosids* from the genus *Agylla*: the forewings are white with a dark grey inner-marginal streak, the hindwings semi-diaphanous brownish-grey, at the border darker. The body is bluish-grey, parts of the palpi, collar, shoulders, base of shoulder-covers, throat and forehips orange, the posterior end of the shoulder-covers, and the venter white. Known only from Cuba.

104. Genus: **Loxozona** *Hmps.*

More stoutly built than *Lymire*, the base of the abdomen above roughly haired. In the veins of the forewings it differs by the 1st median vein rising with the lower radial veins from the same place. Veins of the hindwings not different.

lanceolata.

L. *lanceolata* *Wkr.* (21 h). Anterior body blackish-brown, abdomen with a blue lustre; the palpi are anteriorly white like the sides of the forehead and dots above the eyes, stripes at the legs, and sublateral stripes

on the venter. Shouldercovers striped grey. The blackish-brown forewing is crossed at the cell-end by a broad white band. Expanse of wings: 40 mm. Amazon (Pará).

L. acuminata *Wkr.* (= *hartmanni Schaus*). Head and thorax dark red-brown, chest orange. Abdomen *acuminata*. above blackish, beneath light-brown; orange are the last segment and lateral stripes which on each ring project into the dark dorsal colour in a triangular shape. Forewings dark red-brown, at the base purple-brown; at the cell-end there is a dark crescent, behind it a dark, strongly undulated line turning back to the cell on the upper median vein. Hindwings dark purple brown. Expanse of wings: 36 mm. Brazil.

105. Genus: **Horama** *Hbn.*

Distinguished by the very long hind legs mostly exhibiting a dense hairy fur-cover on the tibiae on two sides, so that the legs appear in the shape of oars. The shaft of the antennae is strongly thickened after the middle, ctenodont or serrate-dentate. The long, narrow wings are densely scaled, usually black or brown. On the forewings the 3 lower subcostal veins are petioled, the two upper ones rise from the cell; on the hindwings the lower median and lower radial vein rise from the lower cell-angle, the 1st median vein from the lower one close in front of the distal margin.

H. panthalon *F.* (= *tibialis Btlr.*) (21 h) differs from the following by the lighter red-brown colour *panthalon*. of the forewings, and the ochreous-yellow hindwings being bordered with blackish-brown; the head is not black. but orange. From Hayti and Venezuela.

H. texana *Grote* (21 h). Wings blackish-brown like the head and thorax. Tips of antennae, palpi, *texana*. forehead, collar, and shoulder-covers spotted or striped orange. Abdomen more bluish-black with orange-yellow margins, on the first segment a white dorsal spot. The second and third segments are ventrally banded white. Anterior and middle legs black, spotted orange; posterior tibiae and tarsi orange, in the middle black, Distributed from Texas through Mexico as far as Honduras, and common.

H. oedipus *Bsd.* (26 m). The body is black, on the forehead, antennae, neck, chest, hips and legs *oedipus*. yellow spots, the collar with white dots, the shoulder-covers, meso- and metathorax bordered with yellow. The first abdominal ring shows a broad, white transverse band, the other rings narrow, yellow ones, the venter being yellow. Wings purple-brown; the costa of the hindwings yellowish. Expanse of wings: 42 mm. Mexico; Guatemala.

H. pennipes *Grote* is one of the smallest species differing from all the others by hyaline spots on the *pennipes*. brownish-black forewings below the cell, in the cell-end and behind it between the upper median and lower radial vein. The body is black, on the forehead, collar, shouldercovers, hips, and legs spotted and striped white; shoulders and chest spotted yellow. The abdomen exhibits beneath and laterally rows of white dots, on the 2 first rings sublateral yellow spots. Venter white. Expanse of wings: 25 mm. Cuba.

H. castrensis *Jones* (21 i). Body blackish-brown, in some places with a slight metallic green lustre; *castrensis*. on each half of the collar 2 white dots; the first abdominal ring subdorsally spotted white, the 2nd and 3rd laterally, the latter also ventrally. The unicolorously blackish-brown wings show a white dot at the costal base. Brazil (Paraná).

H. plumipes *Drury* (= *punctata Guér.*, *jalapensis Neum.*) (21 h). Wings blackish-brown, a white *plumipes*. dot at the base. Head, thorax, and abdomen greenish-black or purple black, spotted or curled white. Antennae black with white tips. Anterior and posterior legs spotted black and white; on the posterior legs the bases of the tibiae and the ends of the tarsi are white, the rest black. Mexico (Jalapa, Orizaba, Misantla, Yucatan: May to November), Honduras, Guatemala, Nicaragua.

H. flavicans *Dogn.* Head, thorax, and abdomen are black; forehead, dots on the collar, hips and *flavicans*. femora beneath white; the distal margin of the shoulder-covers, sides of abdomen, ventral side, and the 3 last rings are yellow. The wings are yellow, on the forewing the costa, subcosta, the median veins, the lower radial, the distal and proximal margins are black, the same on the hindwing. Expanse of wings: 28 mm. Colombia.

H. clavipes *Bsd.* (21 i). Wings reddish-brown, broadly smoky blackish on the margins. At the base *clavipes*. of the forewing a black and metallic bluish-green spot. The black antennae have white tips. Body orange-yellow. On the forehead and collar metallic blue spots; shoulder-covers bordered with black. Abdomen with black rings, which are expanded on the dorsum and surround metallic blue spots. Hips black with blue spots, anterior and middle tibiae and tarsi black and orange; posterior tibiae orange; at the end black, tarsi orange. Mexico (Orizaba, Guerrero), Guatemala, Costa Rica, Venezuela.

H. flavata *Jones*. Head and palpi black and orange, between the antennae a yellow spot; collar *flavata*. greenish-black, bordered with white. Shoulder-covers black, striped red-brown; mesothorax black with 4 yellow-

reddish spots. Abdomen greenish-black, the posterior segmental margins brown; the 1st ring shows above 2 white, laterally large orange spots, the 2 next ones large white, the other rings orange lateral spots. Legs black and orange. Forewings greenish-black, dusted orange, at the base a white dot and 2 orange dots. Hindwing orange, at the border and apex black. Expanse of wings: 30 mm. Paraná.

fulvitarsis. **H. fulvitarsis** *Schrottky*. Head orange, on the vertex dark-brown; palpi orange, at the base dark-brown. Antennae dark-brown, at the tips lighter, above with a blue tint. Collar spotted white. Shoulder-covers dark-brown, with longitudinal orange stripes. Thorax above dark-brown, with anterior white, posterior orange-yellow spots. Abdomen brown, the 1st ring above with 2 white spots and an orange-yellow anal margin, the 2 next segments laterally and beneath with white, the others with orange-yellow spots. Legs brown and orange. Forewings dark-brown, hindwings orange, bordered with brown. Expanse of wings: 30 mm. Argentina. The description of this species having remained unknown to me greatly approximates the preceding.

tarsalis. **H. tarsalis** *Wkr.* (21 h) is easily recognizable by the bronze-green colour on the body and wings. The 1st palpal joint, the forehead, spots on the collar, chest and hips, as well as the ends of the tarsi are orange, as well as subdorsal and sublateral rows of spots on the abdomen. Expanse of wings: 40 mm. Patria unknown.

grotei. **H. grotei** *Btlr.* (21 i) is recognizable by the bare posterior tibiae, only the tarsi being above scaled. Head yellow, palpal terminal joint and a band on the forehead blackish; collar anteriorly black, posteriorly yellow. Thorax above red-brown, shoulder-covers striped yellow. Hips yellow, legs yellow and black. The 1st abdominal ring is blackish-brownish with a blue lustre, posteriorly with yellow rings, the others red-brown. Forewings red-brown, the hindwings more blackish with a yellow costa. Expanse of wings: 44 mm. Jamaica.

diffissa. **H. diffissa** *Grote* (= *pretellus* *H.-Schäff.*) has, like the following species, quite unscaled hindlegs. Head on the vertex purple brown; palpi and antennae yellow, the latter in the middle and at the tips blackish. Collar light yellow, thorax and shoulder-covers brown. Hips yellow, legs brown, tarsi more ochreous. First abdominal ring white, on the lateral tubercles spotted yellow; the 2 next rings are dark-brown, with dorsal and lateral yellow spots, the others light brown. Forewings orange-brown. Hindwings ochreous-yellow with a dark-brown border. Expanse of wings: 35 to 40 mm. Cuba.

pretus. **H. pretus** *Cr.* (= *eumolpus* *F.*, *vespina* *Harr.*) (21 i) has likewise quite unscaled hindlegs and differs from *diffissa* by the pale red-brown ground-colour, unicolorously blackish-brown hindwings, white forehips and the abdomen being black at the last ring, the 1st ring being yellow, not white, the following segments showing black and white ventral and lateral bands. Expanse of wings: 38 mm. St. Thomas; Venezuela.

106. Genus: **Empyreuma** *Hbn.*

The genus contains some very imposing species, of a more or less brilliant red colour, being particularly distributed in the West Indies. A characteristic mark is the hairy forehead, the thorax being very woolly haired, and hair-tufts at the end and at the sides of the last abdominal ring. On the long, narrow forewings the 1st median vein comes from below the lower cell-angle from which the two lower radial veins rise; the two uppermost subcostal veins come separately out of the cell. Hindwings as in *Horama*. ♂ antennae doubly combed.

mucro. **E. mucro** *Zerny* (= *lichas* *F.*, *pugione* *Hbn.*, *sanguinosa* *Martyn*, *sanguinea* *Rothsch.*) (21 k) is blackish-brown on the head and thorax, with minute white spots on the collar, shoulders, shoulder-covers, and hips. Antennae bluish black with orange tips. Abdomen metallic green, above on the 2 first rings spotted white, with white lateral spots. Forewings carmine, except the costa and base of the proximal margin dusted brown. *portoricensis.* Hindwings carmine with black fringes. Expanse of wings: 44 to 56 mm. Cuba; Hayti; Honduras. — **portoricensis** *Rothsch.* is characterized by the duller red colour and broader border of the forewing. Porto Rico.

affinis. **E. affinis** *Rothsch.* differs from *mucro* by the chocolate-brown, not scarlet forewings with a much broader, blackish-brown distal margin; the greatest part of the costa and the base of the proximal margin are carmine. Hindwings carmine with a much broader black border. Cuba. — **haitensis** *Rothsch.* differs by chestnut-red forewings and scarlet hindwings. Hayti; Domingo.

pugione. **E. pugione** *L.* (= *lichas* *Cr.*) (21 i) has a bluish-black thorax and a dull metallic blue abdomen, the latter with white subdorsal spots on the 3rd and 4th rings. Tips of antennae orange. Forewings carmine, dusted blackish, with black, lustrous-blue veins and distal margin. Hindwing carmine with a black marginal band. Expanse of wings: 50 mm. Jamaica. — The egg is light yellow, flattened at the base, finely netted pentagonally. The larva light yellowish-brown, with subdorsal, lateral and sublateral rows of small white spots bordered with blackish-brown; tubercles stellately haired; the 2nd ring shows on subdorsal tubercles long, porrect hairs, on the penultimate ring the hairs are turned backward. The larva lives on oleander.

107. Genus: **Zellatilla** Dyar.

The erect, small palpi extend as far as the middle of the forehead; it differs from the preceding genus by the absence of lateral hair-tufts on the abdomen. The ♂ is without the ventral valve. Antennae in both sexes doubly combed, shaft not thickened. The veins of the wings are almost exactly like in *Empyreuma*, but on the forewings both the lower radial veins do not rise quite from one place; on the hindwings the median veins stand on a long pedicle and rise from below the lower cell-angle, the lower radial vein from it.

Z. columbia Dyar. Body black, the thorax with a faint, the abdomen with a brighter blue lustre; at the base of the 3rd abdominal ring there is a white band being interrupted above, with a sublateral row of white spots. Tips of antennae orange. The orange-yellow forewings being broadly bordered with black are in the disc dusted in a smoky blackish, at the base black; the black distal margin is proximally sinuate. Hindwing towards the apex broadly bordered with black. Expanse of wings: ♂ 40 mm, ♀ 34 mm. Cuba; Colombia.

108. Genus: **Marecidia** Schaus.

The erect palpi are long; antennae shortly combed, at the ends serrate. The posterior tibiae exhibit a very large, glandular swelling which is above filled up with long hairs. On the long, narrow forewings the upper median vein rises with both the lower radials from the lower cell-angle, the upper radial from the upper angle. Hindwings narrow with a convex costal margin. The upper median and lower radial vein rise from the lower cell-angle, the middle radial above it, the upper one is on a short pedicle with the subcostal.

M. sanguipuncta Schaus. Head and thorax black, with metallic green spots and stripes; forehips white. Abdomen above metallic green with black, subdorsal and transverse lines, beneath green with a white basal spot. Forewings black, in the discal area subcostally and above the proximal margin suffused with greenish-blue; at the base there is a carmine spot. Hindwings black with a rosy cellular spot and a whitish inner-marginal stripe. Expanse of wings: 33 mm. Brazil (Sa. Catharina).

109. Genus: **Horamella** gen. nov.

An entirely isolated genus, exhibiting on the one hand resemblances to *Rhynchopyga*, on the other hand undoubtedly being nearer to *Horama*. The proboscis is well developed, the palpi are remarkably slender and thin, smoothly scaled, projecting beyond the forehead almost by the length of the head, and straightly porrect. The antennae, being ciliated in the ♀, combed in the ♂, are not thickened; legs very long and slender, spurs well developed. On the very long, narrow forewing the lower median vein rises far from the lower cell-angle, the upper one likewise a little before it, the lower radial veins on a short pedicle from it, the upper one from the upper cell-angle, the 1st subcostal vein from the cell. On the hindwing the lower median and lower radial vein rise on a long pedicle from the lower cell-angle, the 1st median vein is absent; the middle radial is rather feeble but rises distinctly below the middle of the transverse vein, being at the base rather strongly bent upwards; the 1st radial rises with the subcostal vein pedicellatedly from the upper cell-angle. The veins of the hindwings show the greatest resemblance to those of *Leucopleura*, but the forewings are entirely different. — Type: *H. fassli* Drt.

H. fassli spec. nov. (21 i). This peculiar, small species is undoubtedly one of the most interesting discoveries of the extremely successful explorer. Head and upperside of the thorax black with large, metallic green spots on the vertex and collar. The whole rest of the body is above and beneath of a Pompeian red, of the same colour are the inner margin of the shoulder-covers and a spot on the metathorax. The first abdominal ring shows above a longish-square, white transverse spot being bordered with black; the following rings exhibit triangular, white, small spots growing smaller posteriorly, with a bluish-green iridescence. The unicolorously brown forewings have a white apical spot; the hindwings are brown, in the disc thinly scaled. Antennae and palpi black, legs brown, hips red. Described according to a couple from East Colombia. Type in the Coll. FASSL.

110. Genus: **Leucopleura** Hmps.

The third palpal joint porrect. On the forewings the upper median vein rises before the lower cell-angle, which sends forth both the lower radial veins. The two uppermost subcostals rise on a joint pedicle from the 3 lower ones which are pedicellated. Cell of the hindwing rather short, the lower median and the lower radial vein pedicelled, the 1st median vein being absent; the middle radial from the lower cell-angle, the upper one and the subcostal vein on a short pedicle from the upper cell-angle.

cucadma. **L. cucadma** Druce (21 a) resembles *Cacostatia ossa* (22 c): bluish-black, the body spotted and striped white. Wings at the bases striped metallic blue; the forewings exhibit a hyaline spot below the cell and a post-discal band consisting of 4 spots, the hindwings two narrow hyaline spots below and behind the cell. Panama.

111. Genus: **Loxomima** gen. nov.

Exteriorly looking like a *Loxophlebia* (comp. p. 61 to 64). Palpi rising upwards so long that the middle joint already projects beyond the forehead. Antennae in the ♂ short-combed, in the terminal third serrate. Large ventral valve present. On the forewings the upper median vein rises before the lower cell-angle, the lower radial vein from it, and the middle one separated from it above it; the upper radial vein from below the upper cell-angle. The hindwings similar as in *Leucopleura*. The transverse vein extremely oblique, and the lower half of the cell, therefore, very narrow and short; the middle radial vein, being only feebly developed, rises rather close above the lower cell-angle; the lower one stands on a long pedicle with the lower median vein, from which the upper one rises close before the margin; the upper radial vein and the subcostal come from the upper cell-angle. Only one species.

imitans. **L. imitans** spec. nov. looks almost like *Heliura sanguipalpia* (24 g), but it differs far from it. Body above unicolorously black, posteriorly with a slight blue lustre. Large spots on the sides of the collar and the hair of the anal segment carmine. The hips and the 3 first ventral segments are white. Wings hyaline; veins, margins, apical and inner-angular spots black. Expanse of wings: 22 mm. Sa. Catharina (Joinville). Type in Coll. DRAUDT.

112. Genus: **Pseudosphenoptera** Bltr.

The abdomen is somewhat thinner towards the base, but not strangulated, and shows a feeble cover of hair on the sides of the last segments. The forewings are long and narrow in the ♀, the 1st median vein rises from the lower cell-angle, the lower radial veins from it, the uppermost subcostal from the cell; on the hindwings the lower median vein rises far from the lower cell-angle, the upper one from it shortly before the margin; both the lower radials from the cell-corner, the upper one and the subcostal being pedicelled. We include here *chimaera*, *cocho* and *pitthea* having been described as *Gymnelia*, since Dr. STAUDINGER received *P. basalis* and *pitthea* in copula from different collectors, so that, therefore, the latter probably represents the ♂ of *basalis* of which only ♀♀ are known. In the ♂♂, accordingly, the hindwings would be stunted to a small, triangular rudiment, the veins of which cannot be quite accurately ascertained, owing to this stunted growth.

basalis. **P. basalis** Wkr. (= lanceolatus Bltr.) (22 a) ♀: has a black body, being intermixed with white hair on the forehead, vertex and thorax, and spotted metallic blue on the collar, metathorax, sides of the thorax and legs; the abdomen exhibits on the first segment two white spots and dorsal and subdorsal streaks of metallic blue. The wings are suffused with metallic blue and exhibit at the base a series of hyaline stripes. — *pitthea* Druce (22 a) ♂: has white forehips, the body being otherwise similar. The forewings are hyaline with a black border, the very rudimentary hindwings being black, on the under surface with metallic blue spots. Peru, Amazon.

cocho. **P. cocho** Schaus (22 a) of which only ♂♂ are known, differs from *pitthea* chiefly by black forehips being laterally spotted blue, the hindhips being spotted white and yellow; collar and shoulder-covers are spotted white. The species varies greatly in the extent of the hyaline spots on the forewing: the wings may, like in the figured specimen, be entirely hyaline except the black border, they may also turn more or less black towards the margin, so that there only remain small hyaline spots at the base; in the latter case there appear metallic blue spots on the wing (= *chimaera*?). The hindwings are likewise stunted to a black rudiment. Peru; São Paulo.

chimaera. **G. chimaera** Rothsch. (22 a) is described according to a single ♂ from Peru and has a black body with metallic bluish-green spots, the forehead being grey. The black, distally brownish forewings are spotted metallic blue and exhibit small hyaline spots in and below the base of the cell. The hindwings are reduced to a hair-tuft of about 2 mm length.

113. Genus: **Pseudopompilia** Hmps.

Only one ichneumonid-like species. The first palpal joint is long-haired like a beard. Abdomen at the base somewhat strangulated, at the first segment with lateral tubercles, posteriorly tapering off with scant lateral hair. On the forewings the lower radial veins stand on a long pedicle, on the hindwings the lower radial vein is absent; the upper median vein and the middle radial rise from the lower cell-angle, the upper radial and the subcostal vein are unpetioled.

P. mimica *Druce* (22 k) strikingly copies *Phaeosphecia opaca* (10 c). Posterior tibiae and tarsi striped ochreous-yellow, forehips spotted white. On the bluish-black forewings there is at the base a green silvery spot; below the base of the cell a red-brown stripe in the prolongation of which there is a green silvery, blurred spot. The hindwings are hyaline below the base of the cell. — The species was described from the Amazon, it is before me also from French Guiana (Nouveau Chantier) and East Colombia (Villavicencio), thus apparently widely distributed.

114. Genus: **Xanthopleura** *Hmps.*

The genus contains rather large species mostly resembling *Calonotus*. On the forewings the upper median vein rises near the cell-angle from which the lower radial veins rise. Cell of the hindwing long, the lower median vein far from its lower angle, from which the 1st median vein and the lower radial rise; the middle radial rises rudimentarily from the middle of the transverse vein, the upper one and the subcostal vein on a short pedicle from the upper cell-angle; the costal vein is short and rudimentary.

N. perspicua *Wkr.* (= sandion *Druce*) (21 k) entirely resembles the following species and differs only by the light greenish-yellow colour of the abdominal stripe and a minute hyaline spot above the rise of the 2nd median vein of the forewing. Colombia; Ecuador; Peru (Pachitea); Amazon (Pará).

N. troetschi *Druce* (21 k) is perhaps only a northern race of the preceding; it merely differs by the orange-yellow colour of the abdominal stripes; of the small hyaline spot above the 2nd median of the forewing which is said to be absent, there are anyhow traces noticeable in one specimen before me. Only from Panama (Chiriqui).

N. flavocincta *Guér.* Black, antennae at the base of the shaft striped white; spots on the collar, as well as narrow dorsal and broad lateral stripes on the abdomen are metallic green. Shoulders, chest and legs spotted white. The 1st abdominal ring and the anal tuft are yellow. Some lateral spots on the abdomen are white. Wings hyaline with broad black borders and median band. Expanse of wings: 45 mm. Cayenne.

115. Genus: **Chlorostola** *Hmps.*

Only 2 large species coloured black and golden green, with hyaline spots, erect palpi and doubly combed antennae. Thorax long-haired. On the hindwings the lower median vein rises before the cell-angle, the upper one and the lower radial on a common pedicle, the middle radial being absent. The abdomen shows on the posterior rings lateral, short hair-tufts and on the last segment longer ones.

Ch. interrupta *Wkr.* (22 b) differs from the following species by the abdomen exhibiting metallic green transverse bands above the second and third segments and green subdorsal spots on the other rings, lateral and sublateral rows of white spots. On the forewings the 2 small hyaline spots in the middle of the cell are absent. Mexico.

Ch. corydon *Druce* (22 b). Black, forewings in some places suffused with metallic green, with 2 small hyaline spots in the middle of the cell and one below them, 2 at the cell-end and one below it and 4 behind the cell; hindwings with 3 small hyaline spots at the base and 2 behind the cell. Antennae black, before the tips white. White spots on the collar and shoulders. The abdomen exhibits bluish-white subdorsal spots. Mexico: Jalapa, Orizaba (March to July); Guatemala: Vera Paz.

116. Genus: **Ixylasia** *Btlr.*

It differs from the preceding genus merely by the thorax not being woolly haired and by the absence of hair-tufts on the last rings. On the hindwings the middle radial is imperceptibly represented. Some species show lateral hair-tufts at the base of the abdomen.

I. trogonoides *Wkr.* (22 b). Black; tips of the antennae and palpal base white. Hindhead, collar, shoulders, shoulder-covers, and hips with white dots. The hair-tufts at the abdominal base are brown. Lateral bands on the abdomen and long stripes in the basal half of the black forewing are metallic green. Lateral spots on the 2nd abdominal ring and sublateral rows on the others are white. Hindwings hyaline with black veins and marginal band. Expanse of wings: 56 mm. Brazil.

I. pyroproctis *Druce* (= *kelleri Klages*) has a black body; palpal base and dots behind the eyes are white. Collar, shoulders, shoulder-covers, and thorax spotted white and metallic blue. Forehips spotted white. Hair-tufts at the abdominal base of the ♂ brown and white. The abdomen exhibits on the 1st ring a dorsal bluish-white dot; the last segment and a band at the penultimate ring are above scarlet; laterally and sublaterally there are rows of white spots, the lower ones being longer; the 2 last rings are beneath spotted orange. Wings

hyaline with black veins, margins, discal and apical spots; at the base of the proximal margin of the forewing there is in the ♂ a metallic green stripe. In the ♀ the forehead is white, the body without any blue and white spots. Expanse of wings: 44 to 48 mm. Venezuela.

schausi. **I. schausi** Druce is black; hindhead, collar, shoulders, shoulder-covers, and thorax with bluish-white dots. Hips and a dorsal dot on the 1st abdominal ring are white; moreover, the abdomen shows subdorsal rows of metallic green spots, white lateral spots on the 2nd and 3rd rings and a sublateral row. Forewings black, in the discal area and at the proximal angle metallic green, with minute hyaline spots in the cell-end and below the middle of the cell, a dot at the rise of the lower median vein, and behind the cell between the 1st median and 5th subcostal vein larger spots. Hindwings with a large hyaline spot in the proximal half and a smaller one behind the cell. Expanse of wings: 42 mm. Mexico (Orizaba).

semivitreata. **I. semivitreata** Hmps. (= almon Hmps.) (11 e) looks very much like *Autochloris almon*. Black; small spots on the collar, broad subdorsal abdominal stripes, and the base of the proximal margin on the forewing metallic green. Wings hyaline with black veins, margins and discal spots. Expanse of wings: 54 mm. Brazil (Rio de Janeiro; Blumenau).

117. Genus: **Xantharete** gen. nov.

Proboscis well developed. The obliquely rising palpi project beyond the forehead and are smoothly scaled. Antennae filiform, in the ♀ ciliated, of $\frac{3}{4}$ of the length of the costal margin. On the forewings the lower median vein rises somewhat behind the middle of the median, the upper one before the lower cell-angle, from which the lower radial veins rise, the upper one comes from the upper cell-angle, the 1st subcostal vein from the cell. Hindwings with a broad inner-marginal area the cell short, the lower median vein rises close before the lower cell-angle, the upper one and the 3rd radial on a very long pedicle from it; the middle radial is absent; the upper radial and the subcostal vein stand on a very long pedicle, the costal vein is rudimentarily present, but does not reach the costal margin.

stellans. **X. stellans** spec. nov. (22 b). Head, thorax and legs are blackish-brown, on the collar and shoulder-covers a faint greenish lustre. Abdomen unicolorously orange-yellow. The hyaline forewings show a bright iridescence, the veins are broadly covered with rough blackish-brown scales; the proximal margin being broad blackish-brown as far as to the submedian fold has, in the neighbourhood of vein 1, the shape of a large longitudinal spot intermixed with intensely iridescent, amethyst-coloured scales; the blackish-brown distal margin expands towards the apex; the costal margin and discal spot likewise blackish-brown. The hyaline hindwings have blackish-brown veins and a very broad border, the whole inner-marginal area is blackish-grey. Described according to a ♀ from the Coll. Serritz: East Colombia. Rio Negro, 500 m.

118. Genus: **Phaenarete** Druce.

Head, thorax, and base of abdomen are roughly scaled, at the end of the abdomen feeble lateral hair-tufts. The long-extended forewings do not show any difference in the veins from the usual course; on the hindwings the upper median and the lower radial vein rise pediculate from the cell-angle, the middle radial rudimentarily from the middle of the transverse vein, the upper one and the subcostal vein from the upper cell-angle. — Only one species.

diana. **Ph. diana** Druce (22 b). The body is brown with small white spots at the palpal base, behind the eyes, on the collar, shoulder-covers, and metathorax, hips and tibiae. The abdomen shows subdorsal and lateral white spots. The forewings are hyaline with a broad brown base, discal and apical spot, veins and margins. The hyaline hindwings exhibit a narrower brown distal margin. Panama.

119. Genus: **Cacostatia** Hmps.

Few species of a deep blue reflection, with hyaline spots on the broad wings. Palpi erect, antennae doubly combed. Cell of the hindwing large; the upper median vein rises with the lower radial on a common pedicle from the lower cell-angle, the lower median vein far below it.

sapphira. **C. sapphira** Stgr. (22 c). Black with a deep ultramarine blue, magnificent lustre. At the base of the forewing a large hyaline spot extending yet somewhat into the lower part of the discocellular, a second, oblique, oblong, transparent band is behind the cell and extends from the lower median vein to near the costal margin. Hindwings transparent, with a blackish-blue margin and white inner-angular fringes. Venter and stripes on the legs white. Occurring from Mexico as far as Panama.

ossa. **C. ossa** Druce (22 c) differs from *sapphira* by another hyaline spot between the median veins, the longitudinal spot in the cell is longer extended. Panama, Colombia, Guiana.

flaviventralis. **C. flaviventralis** Dogn. (22 c) has hyaline spots similar to the preceding species, but the ventral side is of a fiery orange-yellow except the black terminal segment. The blue colour is more radiant, brighter. Colombia.

C. discalis *Wkr.* (22 a) has no hyaline spot in the cell and only a very minute spot below the rise of *discalis*. the 2nd median vein. The blue abdomen exhibits white stripes subdorsally, laterally and on the venter. The hyaline hindwings have a rather narrow, bluish-black border. — **assuta** *form. nov.*: the small hyaline spot is *assuta*. larger and extends above beyond the median, and as far as below the rise from the lower median vein; also below the base of the cell there appears another small hyaline spot. Amazon.

C. umbraticola *Klages* is smaller than *discalis* which it otherwise greatly resembles in all parts, but *umbraticola*. with a large, triangular hyaline spot expanding in and below the cell, as well as between the median veins. The proximal margin of the hindwing is black as far as the base; fringes at the proximal angle white. Expanse of wings: 30 to 32 mm. Venezuela.

120. Genus: **Schasiura** *Btlr.*

Distinguished from *Ixylasia* by the unpetioled rise of the upper median and lower radial vein of the hindwing; the middle radial vein is absent.

Sch. mimica *Btlr.* (22c) looks very much like *Ixylasia pyroproctis*. Body black. Forehead and palpal *mimica*. base white, as well as spots on the shoulders, shoulder-covers, thorax and hips, above and at the sides of the 1st abdominal ring. The last ring and a spot on the penultimate are carmine. Wings hyaline with black veins, margins and discal spots. Expanse of wings: 50 mm. Amazon.

Sch. gymnelioides *Zerny* has broader, shorter wings and a stouter shape of the body than *mimica*, *gymnelioides*. and much rather resembles a *Gymnelia* in the habitus. Body black, posteriorly and on the venter with a blue lustre. Anterior body spotted and striped orange. The 2nd to 7th abdominal rings are above narrowly, ventrally broadly bordered with orange. Wings faintly yellowish hyaline; the costal margin of the forewing of an intenser yellow. Veins, the narrow apices of the wings, and an orange-striped inner-marginal longitudinal band black. Hindwings with a broad black proximal margin. Expanse of wings: 35 mm. South America (?).

121. Genus: **Eupyra** *H. Schöff.*

A small group of species greatly reminding us of the genus *Chrysocale* by their exterior: the structure of the body and hairiness, the scheme of colouring and marking are the same. On the forewings the lower radial veins rise in common from the lower cell-angle; on the hindwings, with a comparatively long cell, the lower median vein rises far before the lower cell-angle, the upper one shortly before it, the middle radial, being well developed, rises above it.

E. distincta *Rothsch.* Body black; the chest, a dot on each side behind the eyes, the basal half of *distincta*. the shoulder-covers, and a dot at their apex white. The 3 penultimate abdominal rings with a cream-coloured transverse band. Forewings black, at the base and between the median and lower radial veins dusted with green, 2 hyaline spots in the cell, one below it, one behind it, and on each side of the lower radial vein one. Hindwings black with a purple lustre, a hyaline spot in the cell and one below it; costal margin, median, and proximal angle are of a brilliant metallic blue. Length of forewings: 21 mm. Venezuela.

E. disticta *Hmps.* (22 d). Body black, forehead, collar, shoulders and shoulder-covers, metathorax, hips *disticta*. and ends of the posterior tibiae spotted bluish-white; abdomen with metallic green subdorsal spots, the middle segments on the ventral side white. The forewings, being for the greater part suffused with metallic green, show, in the cell-end, a square hyaline spot and a round one above the middle of the lower median vein; the hindwings are bluish-black, with white spots above and below the lower median vein. Bolivia.

E. imperialis *H.-Schöff.* (= *florella* *Btlr.*) (22 d) has black wings suffused with metallic green, and *imperialis*. with a coppery lustre, which changes into red-violet in the submedian area; black are only the margins and the cell-end; in the latter a square hyaline spot; the hindwings, being dusted with green, have likewise a large hyaline spot in the cell-end. The body is black, the abdomen with a green lustre. Spots on the collar and sub-lateral stripes on the abdomen white. Colombia (Bogotá), Venezuela, Peru. — In **ducalis** *Maass.* the hindwing *ducalis*. exhibits no hyaline spot, whereas the one on the forewing is larger; the green dusting is more extensive. Found in Colombia.

E. affinis *Rothsch.* differs from *imperialis* by the shorter but broader wings, the coppery green, not *affinis*. red colour of the forewings, the green, not black costal margin, the green, not black proximal margin with a black middle spot, and the disc of the hindwing, being green in the ♂, black in the ♀. Peru and Ecuador.

E. sages *Druce* (22 d) differs from the following species by white dorsal spots on the abdomen; the *sages*. forewing, being dusted with green, shows a large, elliptic hyaline spot below the middle of the cell, round hyaline spots in the cell-end and above the 1st median and upper radial vein, between the two latter veins small hyaline dots. The hindwings show long hyaline spots below the cell and at the proximal margin, one in the cell-end, and two small ones behind it. Bolivia. — **reducta** *form. nov.* (22 d) lying before me from Colombia, to a certain *reducta*.

degree forms a transition to the following species: the white dorsal spots are smaller, all the hyaline spots on the wings likewise smaller, on the forewings the spots below the upper radial are absent altogether.

sarama. **E. sarama** Dogn. (22 d) resembles the preceding, but the abdomen does not exhibit any white dorsal spots. The hyaline spots of the forewings are smaller, and there are only three: below the middle of the cell, in the cell-end, and above the upper radial, the latter occasionally with a punctiform spot below it; the hyaline spots on the forewings, being likewise much smaller, are situated below the cell, and a very small one at the proximal margin, one behind the cell. Venezuela.

dorata. **E. dorata** Dogn. has a black body. Between the eyes and on the collar white dots. Spots on the thorax, one dorsal and on each side a double lateral row of spots on the abdomen are golden; underside white. Forewings bronze-golden, at the costal base a white dot; between the median veins is a round, white spot. Hindwings dull black with an oblong coiled and 2 connected small hyaline spots. Expanse of wings: 49 mm. Ecuador (Loja).

consors. **E. consors** Schaus (22 e). Body black; forehead, collar, shoulders, shoulder-covers, and posterior femora with white dots, hips white. Abdomen with broad, golden green lateral stripes, and dorsal and subdorsal rows of white spots. Forewings golden green with black veins and a broad black distal margin; in the upper cell-end a small hyaline spot and a small dot behind it above the upper radial vein. Hindwings black, in the cell and towards the apex with a green lustre, below the cell with some small hyaline stripes which may be reduced to a single one (= ab. 1. *Hmps.*). Expanse of wings: 50 mm. Peru, Bolivia.

psittacus. **E. psittacus** Schaus (22 c) has unmarked wings being dusted quite unicolorously with green. The body is black, on the forehead, collar, shoulders, metathorax, and femora white spots. The abdomen is laterally striped green and shows dorsal and sublateral rows of white spots; the posterior margins of the last segments are yellowish-white. Peru and Bolivia.

122. Genus: **Diaxanthia** *Hmps.*

The anterior body is rather hairy, the palpi are haired above. The forewings exhibit the usual neuration; on the hindwings the lower median vein rises before the lower cell-angle, the upper one from it; the lower radial vein is absent; the middle radial vein strongly bent from below the middle of the cell. Only one species:

lucinia. **D. lucinia** Druce (22 e) has a black body with metallic blue spots. The black forewings exhibit an orange-yellow oblique band extending perhaps from the middle of the innermarginal vein to the middle radial towards the margin; the costal base is orange, too. The hindwings are orange with a black marginal band. Occurring from Costa Rica (Irazu) as far as Panama (Chiriqui).

123. Genus: **Tipulodes** *Bsd.*

Only two small species with long, narrow wings, being characterized by the upper median and lower radial vein of the hindwing rising on a joint, long pedicle from the lower cell-angle; the 2nd median vein rises below it, the middle radial above it; on the forewings the 1st median and the 1st radial vein rise from below the corresponding cell-angles.

ima. **T. ima** Bsd. (22 e). The easily recognizable, small, black and red animal is widely distributed in Brazil, as well as in Paraguay.

rubriceps. **T. rubriceps** Dogn. (22 e) from Colombia is smaller, it has an entirely red head and collar, and the red longitudinal band of the forewing is narrower and ends more pointedly.

124. Genus: **Callopepla** *Hmps.*

Separated from the following, very similar genus by the uppermost subcostal vein of the forewing, rising on a common pedicle with the other subcostal veins. On the hindwings both the lower radial veins come from above the lower cell-angle.

inachia. **C. inachia** Schaus (= *katima* Schaus) (22 e). Black, on the anterior body and legs spotted metallic blue; abdomen of a brilliant blue, the forehips in the ♂ white. Forewings black, at the proximal margin, vein 1 and above it fine orange stripes with an oblique orange band behind the cell. Hindwings black, in the basal half metallic blue. In the ♀♀ the orange oblique spot is united with spots in the cell to a large, triangular discal spot. Expanse of wings: 38 mm. Brazil, Paraguay.

grandis. **C. grandis** Rothschild. Head with antennae and thorax greyish-black. The abdomen is above light metallic blue, beneath brownish-black. Forewings black, in the cell with spot-like orange scales, the proximal

margin, inner-marginal vein and a stripe above it orange as well as a broad, postdiscal oblique band extending from the subcosta to the lower median vein at the margin. Hindwings black, at the base and proximal margin metallic blue. Expanse of wings: 42 mm. Rio Grande do Sul.

C. emarginata *Wkr.* (22 f) shows on the black forewings a large, orange transverse spot, the upper, *emarginata*, proximal corner of which projects towards the base with a long tooth, the basal lower cell-end, however, remains black. Distributed in Brazil.

C. flammula *Hbn.-G.* (22 f) is larger than the preceding and differs from it by the much larger orange *flammula*, spot entirely filling up the cell of the forewing and the upper half of the submedian area. Brazil (Rio de Janeiro; Espiritu Santo).

C. similis *Heyl.* is easily distinguishable from the two preceding by 3 long teeth the orange oblique *similis*, spot sends forth towards the margin below the costa, on the 3rd radial, and below the upper median vein: its proximal border is rounded. Forehead and vertex are spotted metallic blue, thorax and abdomen striped blue. Fringes of the forewings white at the apex, those of the hindwings in the middle white. On the under surface the veins are suffused with blue. Expanse of wings: ♂ 36, ♀ 40 mm. Brazil (São Paulo).

125. Genus: **Cyanopepla** *Clem.*

This genus, with many widely distributed species in Tropical America, contains the most magnificently coloured representatives of the *Syntomidae*. Beside red and yellow spots, intensely lustrous blue and green metal-colours are spread over the wings. The wings are broad, the cell of the hindwing large, the lower median vein rises considerably before the lower cell-angle, from which the upper one and 3rd radial vein rise either separated or on a short pedicle. The middle radial vein rises above it. On the forewing the 1st subcostal vein rises from the cell.

C. scintillans *Btlr.* (22 f) has carmine fringes on both wings, the forewing exhibits a carmine transverse *scintillans*, band, and the base is covered with metallic blue, as well as the body being otherwise black. Costa Rica and Panama.

C. panamensis *Druce* (22 e) entirely resembles the preceding, but the spots and fringes are red-yellow *panamensis*, instead of carmine. Panama (Chiriqui).

C. quadricolor *Fldr.* (22 f). Head and thorax black, suffused with metallic green. Hips white. Abdomen *quadricolor*, of a brilliant metallic green with black angular lines and double, black spots on the last rings; the venter exhibits a white median stripe. Forewings blackish-brown, the base spotted green; below the base of the median there is a short red stripe, fringes purely white, on the ends of the veins yellowish. Hindwings black, in the disc blue, at the margin a carmine, dentate spot. Expanse of wings: 42 mm. Colombia.

C. lystra *Druce* (22 f) has much broader wings than the following, and no orange-yellow costal margin. *lystra*. The fringes are yellowish white at the apex, and the base of the forewing is spotted metallic blue. Colombia.

C. cinctipennis *Wkr.* (= *azetas* *Druce*) (22 g) has entirely black forewings except a very fine, red, small *cinctipennis*, stripe at the base; the costal margin and fringes are orange-yellow; the hindwings are intensely lustrous blue at the base and disc, exhibiting a carmine spot at the margin, and orange-yellow fringes. The abdomen is spotted metallic bluish-green. Colombia, Venezuela, Ecuador. — The typical form exhibits a large red spot on the under surface of the forewing. In **obsolescens** *form. nov.* (= subsp. 1. *Hmps.*) occurring more frequently in *obsolescens*, Ecuador, this spot disappears more or less, all the other red and yellow colours being also greatly reduced.

C. micans *H.-Schäff.* (22 g). The forewings are black at the base, at the proximal margin metallic *micans*, bluish-green, with an orange-yellow spot below the base of the cell, and two smaller ones behind the cell. — ♂-f. **luxurians** *form. nov.*: occasionally there is a streak-like spot in the lower cell-angle also in the ♂, being always *luxurians*, exhibited by the ♀. The deep blue hindwings, with yellow fringes, have a large, orange spot at the distal margin. — In f. **fulgens** *H.-Schäff.* (22 g) the orange-yellow spots are carmine. Both forms are found in Colombia and *fulgens*, Venezuela.

C. fastuosa *Wkr.* (= *fulgida* *H.-Schäff.*) (22 g). The blackish-brown forewings, being metallic blue *fastuosa*, at the base, exhibit below the base of the cell, and in the cell-end, one red spot each, the hindwings, with a blue lustre, show a large red spot at the distal margin. On the under surface of the forewing there is also a small red spot behind the lower cell-angle, appearing sometimes also above. From Venezuela to Brazil, occurring also in Jamaica.

C. alonzo *Btlr.* (= *imogena* *Btlr.*) (22 g). Like *fastuosa*, but besides with a red oblique band behind *alonzo*, the cell. Common in Colombia, Bolivia, Venezuela, Ecuador, and Peru.

C. arrogans *Wkr.* (22 a). The black forewings, being metallic bluish-green at the base, exhibit 3 dark *arrogans*, orange-red spots: an oblong one below the cell, a small square one at the cell-end, and a large, oblique subapical

- band. The black hindwings, being likewise blue at the base, exhibit at the border a large, irregular, scarlet spot. Body metallic bluish-green with an extraordinarily intense lustre. Forehips white. On the under surface of the wings the metallic bluish-green is much more extensive than above. Distributed from Mexico (Orizaba, Vera Cruz, Cordoba) through Honduras, Guatemala, Costa Rica, Panama as far as Venezuela. — ab. **costaricensis** Druce (22 h) occurring in Costa Rica and Panama (Chiriqui), has a yellowish-red, not scarlet marginal spot of the hindwing.
- xenodice.* **C. xenodice** Druce (22 h). Blackish-brown; anterior body and legs spotted metallic green, abdomen finely curled green. Forewing at the costal base with a green dot; behind the cell there is a large, orange spot.
- pallascens.* Hindwings suffused with blue, with a triangular orange spot behind the cell. Costa Rica. — In ab. **pallascens** ab. nov. (= ab. 1. *Hmps.*) the orange spots are much lighter.
- submacula.* **C. submacula** Wkr. (22 h) is distinguished by yellow spots being more or less tinted orange-red at the margins: a stripe below the cell and a transverse band behind the cell. On the black hindwings suffused with blue, behind and below the cell, one small red spot each shines through, being beneath large and distinct. Venezuela. — Whereas the name-type has the costal margin carmine in the basal half, in Central American
- borealis.* specimens: — subsp. **borealis** Rothsch. this costal margin is generally blackish-brown; the red submedian band is much broader, the hindwings are not spotted red, and the body is much more extensively suffused with a bluish-green silvery colour. Mexico, Guatemala, Honduras, Panama.
- melinda.* **C. melinda** Dyar. Black; on the thorax and abdomen suffused with bluish-green, also on head, palpi and legs; hips, tibiae, tarsi and venter dusted with white. Forewings with a metallic blue dot at the costal base and a similar stripe in the submedian area; from the cell-end, a carmine band runs to the proximal angle, and a smaller oblique spot is situate towards the apex between the middle radial and the lowest subcostal vein. Hindwing in the basal two thirds of a bluish-green lustre with a round, red spot before the margin between the lower median and lower radial vein, being intersected in black by the upper median vein. Expanse of wings: 41 mm. Brazil (Petropolis). The description runs very similarly to that of *Napata banghaasi* (21 d) described by me, which, however, is surely a *Napata*, so that the name *Melinda* must perhaps be placed there.
- jucunda.* **C. jucunda** Wkr. (= *fastuosa* Mén.) (22 h) is much smaller than the preceding, on the forewings the same markings, but the spots are unicolorously carmine. The hindwings are of a more intense blue lustre and do not exhibit any red spots at all. Distributed from Brazil to Paraguay, Uruguay and Argentina.
- griseldis.* **C. griseldis** Druce (22 k) differs greatly from all the other species by almost entirely red forewings and entirely black hindwings. Fringes at the apices of the wings white. Mexico.
- bella.* **C. bella** Guér. (= *cruenta* Clem., *haematodes* Bsd.). The nomenclatural type is a rare form with orange-yellow spots on the forewings; a long spot extends through the cell, one part being also yet situate below the median, another oval spot is behind the cell; in the type these spots are connected, and as often as not separated. On vein 1 and at the proximal margin there extends one metallic blue stripe each. The hindwings are entirely black, at the base suffused with metallic bluish-green. The whole body and the under surface are of a magnificent
- gloriosa.* metallic blue. In the ♀ the blue is very much less extensive. — **gloriosa** Wkr. (22 i) is the most common form,
- bivulnerata.* in which the spots of the forewings are scarlet and separated. — In **bivulnerata** Grote a. Rob. the cellular spot
- eximia.* is much broader; — and in **eximia** Bsd. the two red spots are combined to one. — The species and its forms fly in Mexico, British Honduras, and Guatemala.
- julia.* **C. julia** Druce (22 i), on the black wings, being striped metallic blue towards the base, shows a broad, carmine, oblique postdiscal band; the blue hindwings are bordered with black, the fringes at the apex white. From Peru, Brazil, and Paraguay.
- orbana.* **C. orbana** Druce (22 i). Black. Head, thorax and legs spotted metallic blue; abdomen dorsally and laterally striped blue, beneath white. On the forewings the costal base is striped blue; behind the cell is a broad, orange oblique band from the subcosta to the margin above the lower median vein. Expanse of wings: 44 mm. Sa. Catharina; Argentina.
- imperialis.* **C. imperialis** Druce (22 i). Body black with a brilliant blue lustre. Forewings blackish-brown; bluish-green are: a dot at the costal base, a stripe above the inner-marginal vein, and a shorter one at the base of the proximal margin; a large, carmine oblique spot extends from the subcosta behind the cell to the proximal angle. Hindwings of a brilliant blue with a black apex. Expanse of wings: 38 mm. Ecuador.
- beata.* **C. beata** Rothsch. is distinguished by very narrow wings. The body is lustrous metallic blue. Forewings black with a blue subcostal stripe; a long, carmine, cuneiform spot extends from the base to the margin between the inner-marginal vein and the median. Hindwings black with a carmine apical spot. Expanse of wings: 28 to 32 mm. Panama (Chiriqui).
- phoenicia.* **C. phoenicia** Hmps. (22 k). This pretty species, being on both wings marked with one very large, red spot each, is unmistakable. It seems only to fly in Brazil.

C. samarca *Schaus* (22 k) bears an extraordinary resemblance to the preceding, but it is smaller *samarca*. and of a much more graceful structure. Palpi above black, beneath white. Body above of a brilliant blue, abdomen with subdorsal and lateral white stripes, below which there is a black sublateral band, the underside being white; forehips white. Wings almost exactly coloured and marked as in the preceding. Expanse of wings: 25 mm. Bolivia.

C. amata *Druce* (22 i) is very much like *phoenicia*, but the red spot of the forewing is smaller and *amata*. does not extend as far as the base; on the hindwings the red is confined to an oval antemarginal spot, the inner-marginal area being broad and extensively metallic blue, and on the forewing the blue basal spot is considerably larger, too; the ♂ shows almost no red at all on the hindwings above. The species is besides considerably larger. Colombia; Peru (Chanchamayo).

C. baroni *Rothsch.* Head and collar metallic green, abdomen above metallic blue, the underside is *baroni*. yellow. Forewings chocolate-brown, costa, and base of the inner margin orange, below the base of the cell a short scarlet stripe. Hindwings dark brown, fringes yellow and orange. A large, cuneiform discal spot, being metallic blue in the proximal half, distally red, extends from the base to the margin. Ecuador.

C. hurama *Bltr.* (22 k) has the forewings marked similarly as in *alonzo*, but the streak in the cell- *hurama*. end is longer. The hindwings are entirely black, with a blue tinge at the base, and broad, yellowish-white fringes. Ecuador, Bolivia, Amazon. — In *subgloriosa* *Stgr.* (22 a) there appear bluish-green, silvery, postdiscal stripes *subgloriosa*. in the cell-spaces.

C. pretiosa *Burm.* Blackish-brown, suffused with metallic blue. Forehips, femora and tibiae inside *pretiosa*. white. Forewings at the base with blue spots; in and below the base of the cell, as well as behind the lower cell-angle there are carmine spots. Hindwings blue. Fringes of both wings white. Expanse of wings: 24 mm. Argentina.

C. perilla *Druce* (23 a). Head and thorax blackish-brown, with bluish-green spots, the abdomen *perilla*. with narrow, metallic green segmental lines. The brown forewings exhibit a bluish-green spot at the base of the costal margin, below the base of the cell, and behind the cell, small red spots. The hindwings are, in the ♀, red in the larger costal halves. Known only from Ecuador.

C. basimacula *Hmps.* (23 a) is distinguished by deep-blue hindwings being bordered with black, *basimacula*. without any red above, whilst it is so beneath; the brown forewings are spotted bluish-green, at the base with a small carmine spot below the base of the cell, beneath extensively blue with a large, red, post-discal spot. The abdomen is of an extremely intensely metallic lustrous light bluish-green, with a white ventral stripe. Fringes of the hindwings white. Amazon, Ecuador.

C. berthia *Druce* (22 k). The body is blackish-brown, with green spots on the head, thorax and legs, *berthia*. the abdomen finely curled in a metallic green. Forewings dark brown, with green stripes at the costal base, carmine stripes below the cell-base. Hindwings suffused with blue, with a carmine spot behind the cell, turning round the lower cell-angle. Expanse of wings: 40 mm. Ecuador.

C. obscura *Druce* (22 k) extremely resembles *chloë*, but the fringes of the forewings are brown, those *obscura*. of the hindwings whitish. The underside is extensively metallic blue, without any red spots. Peru.

C. buckleyi *Druce* (23 a) is one of the largest species, greatly resembling *berthia* above, though *buckleyi*. it is very much distinguished by quite orange-yellow fringes. The abdomen, being blackish-brown above, with silvery green ring-indentations, is beneath entirely golden green. The hindwings exhibit a large red spot behind the cell and 2 sharply defined ones below it. Ecuador and Bolivia.

C. chloe *Druce* (23 a) is much smaller than the preceding, the hindwings exhibit only a small red *chloe*. spot behind the cell at the costal margin. The forewings are beneath not spotted red behind the cell, as is the case in *buckleyi*. Ecuador.

C. agyrtidia *Hmps.* (23 b) is one of the smallest species resembling *Agyrta*, with a large, cuneiform *agyrtidia*. hyaline spot below the cell, and a postdiscal spot being composed of 3 spots, the hindwings being extensively hyaline, with a black border and white proximal margin. Forehead, collar and shoulder-covers spotted white, legs striped white; the abdomen is suffused with blue, and beneath white. Peru (Pachitea); Bolivia.

C. chelidon *Druce* (23 b) is very easily recognizable by the large, postdiscal hyaline spot being *chelidon*. bordered with smalt; the forewings, being otherwise black, exhibit metallic light blue stripes subcostally and on vein 1. The hindwings exhibit a narrow hyaline stripe bordered with blue in, below and behind the cell. The fringes at the apex of the forewing are white. Distributed from Colombia to the Amazon.

C. glaucopoides *Wkr.* (23 b) is smaller than the preceding, the postdiscal hyaline spot of the forewing *glaucopoides*. is not bordered with blue, on the whole somewhat smaller and narrower; the metallic greenish-blue stripes on the innermarginal vein and the subcostal are much narrower. Peru, Venezuela, Amazon.

C. dognini *Rothsch.* Head, antennae, and terminal joint of the palpi black, the rest of the palpi *dognini*. and chest orange-yellow, thorax sooty blackish-brown. Abdomen black, suffused with purple blue, with an

orange anal tuft. Forewings blackish-brown with grey veins. A large, cream-coloured spot behind the cell and a small indistinct one between the median veins; fringes at the apex white, otherwise grey. Hindwings black, suffused with purple blue, fringes white. Length of forewings: 18 mm. Paraná; Paraguay.

girardi. **C. girardi** Dogn. differs from *dognini* by its somewhat smaller size, black palpi being anteriorly white-haired, yellow spots on the shoulders and mesothorax, the abdomen being more bluish-green with white dorsal and lateral dots, and the anal tuft being only beneath white, not orange; collar black, with white dots, laterally white. The spots on the forewings are white. Expanse of wings: 20 mm. Argentina.

perspicua. **C. perspicua** Schaus. Head black, neck red. Thorax and abdomen above dark blue, the latter subdorsally whitish. Shoulder-covers brown, striped white and bordered with blue. Underside white. Legs blue and white with brown tarsi. Forewings black, with a large hyaline area in and below the cell, below and above the lower median vein; behind the cell an oblique hyaline band from the subcosta to the distal margin; above the submedian a lavender-grey stripe. Hindwings hyaline with dark blue veins and margins. Expanse of wings: 35 mm. Bolivia.

hyaloptera. **C. hyaloptera** Dogn. is larger than the preceding, the body very similar, palpal base dark red; thorax and abdomen dorsally striped white. The wings are much more extensively hyaline, of a bluish milky iridescence; there only remain black: uniformly narrow margins and an oblique band at the cell-end extending from the costa to the distal margin between the median veins, as well as the veins with a deep blue lustre. Expanse of wings: 42 to 44 mm. Colombia.

ribbei. **C. ribbei** Druce (23 b) is a larger, broad-winged species, with a black body of an intense blue lustre, and an orange-yellow first palpal joint, hindhead and neck; sides of the forehead, hips and venter white. The intensely lustrous blue forewings exhibit a hyaline band behind the cell, the hindwings show insignificant, small hyaline stripes near the border between the median and radial veins. Panama.

masia. **C. masia** Dogn. (23 b). Black with a blue lustre. The 1st palpal joint, neck and collar carmine; sides of forehead white. Abdomen dorsally white. On the broad forewings there is a hyaline band behind the cell, extending from the lowest subcostal vein to below the lower median vein and turning beneath somewhat round the lower cell-end; the veins traversing it are scaled blue and white. On the hindwings there are traces of small hyaline spots. Between the upper median and middle radial vein the ends of the fringes are white. Expanse of wings: 46 mm. Ecuador.

126. Genus: **Desmotricha** Hmps.

Base of abdomen roughly haired. On the forewings the uppermost radial rises below the upper cell-angle. The cell of the hindwing is long, from the lower cell-angle there rise the 1st median and 3rd radial veins, the middle radial above it. The under surface in the ♂ is covered with rough scent-scales or hair. More than a dozen of mostly brown species marked with yellow transverse spots.

ursula. **D. ursula** Cr. (23 c) is one of the larger species, distinguished by the yellow oblique band of the forewing, extending from the costal margin to the proximal angle; the veins in the basal half are indistinctly striped yellow. The underside of the body is yellow. The under surface of the hindwings is bluish-grey in the inner-marginal half. Widely distributed from Costa Rica through Colombia and Guiana, the Amazon down as far as Sa. Catharina.

trita. **D. trita** Dogn. is much smaller than the preceding, distinguished by the entire black collar and shoulder-covers, the abdomen being lustrous blue above, blackish-brown beneath. On the forewings the veins are not marked yellow; the hindwings exhibit a club-shaped spot between the 2nd median and 3rd radial vein. Expanse of wings: 30 to 31 mm. Colombia; Ecuador.

metapolia. **D. metapolia** Dogn. is allied to *trita*. Thorax and forewings dull black with a somewhat greenish tint; abdomen and hindwings more lustrous blue. The underside of the abdomen is whitish, so is the inner-marginal half of the hindwing beneath. Forewing with a broad, yellow transverse band behind the cell, not touching the costa. Hindwings unmarked. Expanse of wings: 30 mm. Colombia.

nitens. **D. nitens** Rothsch. is distinguished by an intense purple lustre on the thorax and abdomen, the latter being sublaterally striped white. The chest, the inside of the brown legs, the front of the palpi, and 2 small spots on the black head are white. The blackish-brown forewings show a broad, vermilion-reddish oblique band behind the cell from the costal margin to the proximal angle; hindwings with a very intense purple lustre. Length of forewings: 20 mm. Venezuela.

similis. **D. similis** Rothsch. is much larger and has broader wings than *nitens*. The body and the forewings are of a purer black, the veins of the forewings marked lighter, the oblique band is orange-reddish. The hindwings are black in the costal halves, towards the proximal margin sooty grey. Length of forewings: 22 mm. Amazon.

D. imitata Druce (23 b). The blackish-brown body shows a purple blue lustre on the forehead. hips *imitata*. and abdomen. The forewings exhibit a round, orange spot in the cell-end and a square one behind it. On the hindwing there is in the costal half a large, orange spot, in which there is a brown discal streak cohering with the costal margin. Expanse of wings: 40 mm. Ecuador.

D. obliqua Schaus (23 e) exhibits, on the forewing, a yellow oblique band crossing the cell, and *obliqua*. orange-yellow hindwings being very broadly bordered with blackish-brown. Front of palpi white, so is the lower part of the forehead, the upper part being orange, as well as spots on the collar and shoulders, and the posterior margins of the abdominal rings. Venter white. Brazil (São Paulo, Rio de Janeiro).

D. albicincta Hmps. is smaller than the preceding which it greatly resembles, distinguished by *albicincta*. the yellowish-white forehead and equally striped shoulder-covers, and white-curved abdomen; the veins, costa, and submedian fold are striped lighter; the hindwings are more extensively blackish-brown, in and below the cell dusted yellow, with a yellow oblique spot behind the cell. Beneath the bases of the wings are strewn with white. Expanse of wings: 30 mm. Venezuela.

D. klagesi Rothsch. Head orange-reddish, antennae brown. Collar olive; thorax brown, the shoulder- *klagesi*. covers striped and bordered with olive. The abdomen is above blackish-brown, beneath white. Forewings dark brown, subeostally, on the median, submedian fold and inner-marginal vein striped greyish-yellow; behind the cell is a broad, orange-reddish oblique band extending from the costa to the proximal angle. On the hindwings in the ♂ the proximal two thirds are semidiaphanous blackish-grey, the distal third brownish-black; in the ♀ the hindwings are quite brownish-black, in the basal part only slightly diaphanous. Length of forewings: 18 mm. Amazon; Venezuela.

D. perplexa Rothsch. differs from *klagesi* by much broader forewings with a much smaller oblique *perplexa*. band, the hindwings being unicolorously blackish-brown, and the venter brown, not white. Amazon.

D. hoffmannsi Rothsch. differs from *perplexa* by narrower wings. The hindwings above exhibit a *hoffmannsi*. broad, reddish orange-yellow, longitudinal band in the middle, extending from the base to the margin; beneath they are equally marked, with a broad, greyish-white proximal margin. Peru and Bolivia.

D. oecola Dyar, which is known to me only from the description, seems to be allied to *klagesi oecola*. and its allies. Head and thorax brownish black; along the inner margin of the shoulder-covers runs a yellow line across the collar as far as the base of the antennae. Abdomen above bluish-black, beneath more greyish-black. Forewings blackish-brown, the veins towards the base with yellowish stripes, with the usual ochreous-yellow oblique band from the costal margin to the proximal angle. Hindwings bluish-black, beneath at the margin grey. Expanse of wings: 38 mm. Mexico (Orizaba).

D. aurimacula Schaus (23 c). Body blackish-brown, forehead and underside as well as the posterior *aurimacula*. margins of the abdominal rings white; collar and shoulders spotted yellow. The brown forewing exhibits a yellow oblique band behind the cell; the black hindwing a white longitudinal spot in the centre. From Colombia, Venezuela, and French Guiana (Nouveau Chantier).

D. parva Rothsch. (23 c) is the smallest species with narrow brown wings, and a yellow, oval, oblique *parva*. spot on the forewing, partly penetrating into the cell. The under surface is whitish. Venezuela, French Guiana.

D. uniformis Hmps. (23 e) differs from all the other species by the uniformly light yellowish-brown *uniformis*. colour on the body and wings, only the palpal base, forehead, basal joint of the antennae, and throat being carmine like the anal hairing and the posterior margins of the ventral segments; the upperside of the abdomen is somewhat darker brown. From Rio de Janeiro.

127. Genus: **Coreura** Wkr.

A small group of large, magnificently coloured species, rather unlike the *Syntomidae*, and resembling certain *Hypsiidae*. The long palpi are straightly porrect; head and thorax covered with woolly hair. On the forewing the 1st median vein rises from the lower cell-angle, the lower radial above it, the upper radial vein from below the upper cell-angle. On the hindwing the upper median and lower radial vein rise from the lower cell-angle, the middle radial vein above it; the lowest subcostal vein rises before the upper cell-angle. Very peculiar are the secondary sexual marks of the ♂ of some species, consisting of bare, unscaled patches on the under surface of the forewings and being accompanied by peculiar fusions of veins.

Sect. I. ♂ on the under surface of the forewings with bare stripes above and below the 2nd radial, both the upper radial veins being fused in the middle of their course. In the ♀ the 2nd radial is rudimentary.

C. euchromioides Wkr. (23 e). The red collar makes the species well recognizable; the hindwings *euchromioides*. in the ♂ are above quite blue, only beneath provided with a series of small, red, triangular, marginal spots, in

the ♀ the red band of the forewing is broader and extends at the costal margin for some distance towards the base; the hindwings exhibit also above a red marginal band. Colombia; Venezuela.

lysima- **C. lysimachides** Druce (23 d) differs from the preceding by the black collar, white forehips, and the
des. margin of the hindwing being red also in the ♂. Ecuador; Peru.

adamsi. **C. adamsi** Lathy differs from *lysimachides* by the black head, being somewhat red only in the neck, and by the absence of the red marginal band on the hindwings above; only the fringes are carmine. On the forewings the red oblique band at the proximal angle is strongly narrowed and dusted with orange. Fringes at the apex white. Ecuador.

eion. **C. eion** Druce (26 i) is black, on the body suffused with metallic blue; forehips in the ♂ white. Forewings at the base and in the cell striped blue; a broad, orange-yellow band extends from the costal middle to the proximal angle. The hindwings are of a brilliant blue in the basal halves, at the border there is an orange band, not reaching the apex and proximal angle and being expanded to a spot between the median veins. Expanse of wings: 42 mm. Costa Rica, Panama.

Sect. II. ♂ forewings with normal veins, but with 2 bare stripes on the under surface of the forewings.

interposita. **C. interposita** Hmps. Black, with a blue lustre. Palpal base, prothorax, and neck orange, forehead bluish-white. Shoulder-covers, thorax, abdomen, and legs striped white. The forewings are striped white on the submedian fold; behind the cell, between the lowest subcostal and lower median vein, there is a white oblique band. Hindwings of a brilliant metallic blue, fringes white. Expanse of wings: 40 mm. Venezuela.

albicosta. **C. albicosta** spec. nov. (23 d) is recognizable by the snow-white costal margin of the ♂ forewing, which, however, seems to be soon worn off by flying. The head is quite scarlet, also the palpi, except the black terminal joint; forehead, hips and shoulders white. The forewings exhibit a narrow, red oblique band, in which the veins do not appear white; the distal margin of the hindwing is narrow red. Beneath the red bands are somewhat broader than above. In the ♂, the forehead, forehips, shoulders, and costal margin are black. Obtained in numbers of both sexes from Mexico (Presidio, Vera Cruz).

Sect. III. ♂ forewings normal, without any bare stripes.

fida. **C. fida** Hbn. (= *atavia* Hmps.) (23 d). Black with a deep blue lustre; the 2 first palpal joints, vertex and throat carmine. A broad, carmine oblique band behind the cell of the forewing extends from the costa to the proximal angle, growing a little narrower from the lower median vein towards the proximal margin and being traversed by whitish-dusted veins. The hindwing exhibits a broad, carmine marginal band with an undulated, proximal bordering. Expanse of wings: 50 mm. Widely distributed in Brazil. The statement „Mexico“ refers perhaps to *albicosta*.

engelkei. **C. engelkei** Rothsch. differs from *fida* by its smaller size, quite red palpi, red margins of the collar, white chest, and unicolorously brilliant lustrous blue hindwings with red fringes. Length of forewings: 21 mm. North Colombia (Sa. Marta).

hampsoni. **C. hampsoni** Dogn. is distinguished by quite unicolorously black forewings with white fringes at the apex. Hindwings metallic blue, with a fine scarlet marginal line and red fringes. Beneath the forewing shows a broad, red oblique band, the hindwing a broader marginal band. Head black, on the forehead white and bluish, the hindhead a little red. Thorax black; abdomen above deep blue, beneath with a metallic lustre. Palpal terminal joint black, the two first ones black mixed with red. Expanse of wings: 46 mm. Ecuador.

alcedo. **C. alcedo** spec. nov. (23 d) somewhat resembles *Ctenucha virginica* and has a black body being suffused with a bright metallic greenish-blue. The palpi, except the black terminal joint, a stripe between the antennae, the throat, forehips, and neck are orange; of the same colour are beneath the 4 last abdominal rings, the anal hairing, and dorsal spots growing larger posteriorly on the 3 last rings above. The forewings are black, at the base of a bright bluish-green; in the marginal half between the veins with a dull bluish-green lustre. The black hindwings exhibit a very intense, peacock-blue lustre on being exposed obliquely to the light. Fringes of the forewings white, of the hindwings blackish-grey. Under surface like above. Described according to a ♂ without the patria being stated (BANG-HAAS).

128. Genus: **Aclytia** Hbn.

This genus contains a number of mostly dark coloured species with a metallic abdomen which is covered with long hair at the base. The ♂ exhibits a distensible hair-tuft in a fold on the anterior tibiae. On the hindwing the lower cell-angle is very much produced, the discocellular forms an acute angle. The lower median vein rises far from the lower cell-angle, the upper one and the 3rd radial from it on a long pedicle, and the middle radial vein above it.

A. mariamne *Druce* (23 d). Body black, with a blue lustre. Palpal base, hips, and a middle stripe *mariamne* on the venter white. The wings are black, in the basal halves metallie blue, on the hindwing more extensive. The hindwings exhibit an orange oblique band from the costal centre to the proximal angle. Expanse of wings; 38 mm. Colombia.

A. flavicaput *Rothsch.* Head and neck orange, vertex black. Thorax sooty black, shoulder-covers *flavicaput* striped yellowish-grey. Chest and underside of abdomen orange. Abdomen above lustrous greenish-blue with a broad, sooty black dorsal band on the 4 first rings. Forewings brownish-black with lighter veins. Hindwings bluish-black with a white, transparent discal area. Length of forewings: 16 mm. Colombia; Venezuela; Guiana.

A. flavigutta *Wkr.* (= *simulatrix* *Wkr.*) (23 e). Blackish-brown; the front of the palpi, hips, and *flavigutta* a median stripe on the venter are white. The hindhead, collar and shoulders are spotted orange. Abdomen with broad, metallic blue lateral stripes. Forewings blackish-brown with yellowish veins and, in the ♂, round orange discal spot, in the ♀, an oblique band. Hindwings black with hyaline stripes in the disc. Expanse of wings: 34 mm. São Paulo.

A. punctata *Btlr.* (= *heber* *Wkr.*) (23 e) is recognizable by the base of the palpi, forehips and ventral *punctata* side being white. The abdomen is only laterally striped bluish-green, the dorsum remains blackish-brown. The veins of the basal half of the forewing are striped yellowish-grey. The nomenclatural type shows a yellow, small spot at the transverse vein, which is entirely absent in **astigma** *Strand*, whilst it grows to a large, yellow, *astigma* round spot in — **megastigma** *Strand*. Distributed from British Honduras through Guatemala, Costa Rica *megastigma* as far as Pará.

A. petra *Schaus.* Blackish-brown; palpi, sides of the forehead, and hindhead spotted and striped *petra* white. Forehead and lateral spots on the abdomen metallic blue, venter white. Forewings blackish-brown with darker veins. Hindwings hyaline with black veins and margins. Expanse of wings: 34 mm. Peru.

A. klagesi *Rothsch.* (23 e) is immediately recognizable by the subdorsal, black abdominal stripes on *klagesi* the 4 first rings, which are united to a dorsal stripe beginning from the 5th ring. Hips and venter isabel-coloured, forehead metallie blue. The forewings are unicolorously brown. Distinguished from *terra* by the yellowish-white underside. From Venezuela and Bolivia.

A. affinis *Rothsch.* differs from *klagesi* by its purely white chest and underside of the abdomen, *affinis* smaller size, only one black dorsal band on the abdomen, and with a reduced white, only very little transparent disc of the hindwing. Length of forewings: 15 mm. Venezuela.

A. coeruleonitens *Rothsch.* Head and thorax blackish-brown; palpal base and small spots on the *coeruleo-* collar orange; chest and venter white. Abdomen lustrous greenish-blue, the 1st ring above spotted sooty black. *nitens* Forewings brownish-black, hindwings bluish-black with a white, transparent disc. Length of forewings: 16 mm. East Bolivia.

A. hoffmannsi *Rothsch.* (23 e) is recognizable by the orange-yellow basal joint of the palpi, the underside *hoffmannsi* being white. The collar shows laterally a small, orange-yellow spot which may also be absent. Shoulder-covers striped grey; abdomen above blue. The forewings are brown, the veins in the basal half striped yellowish-grey, at the cell-end a round, orange-yellow spot to which, in some specimens, a yellow streak is attached below, which in its further development may grow into a yellow oblique band: **taeniata** *form. nov.* (23 e). — Numerous *taeniata* specimens of every possible transitions from Peru, and also from Cuyaba (Matto Grosso).

A. jonesi *Rothsch.* Head blackish-brown, thorax more greyish-brown, on the shoulder-covers striped *jonesi* yellowish-grey. Neck, distal half of the collar, and a spot at the base of the forewing orange. Chest and venter white. Abdomen sooty black, with lustrous bluish-green lateral spots. Forewings velvety brown with greyish-yellow veins, at the cell-end there is a brilliant orange-yellow spot. Hindwings bluish-black, in the disc hyaline white. Length of forewings: 19 mm. São Paulo; Paraná.

A. reducta *Rothsch.* Head and antennae black; thorax blackish-brown with 2 white, small discal *reducta* spots. Abdomen above lustrous bluish-green with a broad, black dorsal band, beneath white, like the chest. Forewings brownish-black with an orange spot at the cell-end. Hindwings black with a strongly reduced, hyaline white disc. Length of forewings: 16,5 mm. Venezuela.

A. albistriga *Schaus.* Head and thorax black; forehead and shoulder-covers striped white; 1st palpal *albistriga* joint, spots on the hindhead and on the sides of the collar ochreous-yellow. Abdomen above blue, beneath white, like the hips. Forewings black, veins at the base grey; across the cell-end runs a white oblique stripe from the subcosta to the proximal angle. Hindwings blackish-blue with a broad hyaline stripe below the cell; shorter, small hyaline spots are in the cell-end, between the median veins and at the base of the proximal margin. Expanse of wings: 31 mm. Costa Rica.

A. gynamorpha *Hmps.* (= *flavigutta* *Btlr.*) (23 e). Deep blackish-brown, palpal base, forehead, vertex, *gyna-* collar, and hips spotted orange. Abdomen suffused with blue, beneath on the first 6 rings orange-yellow. The *morpha* blackish-brown forewings also in the ♂ exhibit a broad, orange-yellow transverse band, the black hindwings with a blue lustre are hyaline in the disc. French Guiana, Amazon.

- heber.* **A. heber** Cr. (= *halys* Cr., *flaviventris* Möschl.) (23 f), from Mexico to Brazil, differs from *ventralis* by the presence of a round, yolk-coloured discal spot in the ♂, whereas the ♀ has a broad, oblique, yellow band. Besides, the palpal base, 2 spots on the forehead and on the vertex orange; the hips are orange-yellow in both sexes. Of this extremely common insect there are 8 specimens of both sexes before me from Mexico (Orizaba, *insignata*. Misantla), which I denominate — **insignata** ab. nov. (23 f). It has above no traces whatever of the yellow spots; beneath they are usually slightly indicated at the costal margin. The animal thereby greatly resembles *ventralis* and *terra*.
- ventralis.* **A. ventralis** Guér. (= *conspicua* Druce, *lucania* Schaus) (23 f), from Mexico and Central America as far as Panama, has dark blackish-brown forewings, transparent, hyaline hindwings with a greyish-black, irregular border. Vertex, as well as dorsal and lateral spots on the abdomen metallic blue. Collar and shoulders with small red spots. Venter yolk-coloured. In the ♂ the hips are orange-yellow.
- terra.* **A. terra** Schaus (23 f) entirely resembles *ventralis*, but it has no orange-red spots on the collar and shoulders. The subdorsal black colour of the abdomen is united to a broad dorsal stripe on the posterior rings. The ♀ is without the orange colouring of the hips and ventral side. *klagesi* is similar, but its underside is isabel-coloured. From Brazil and Paraguay.
- bractea.* **A. bractea** Möschl. (23 f). Anterior body and wings blackish-brown. Palpal base, sides of forehead, hindhead, shoulders, throat, and hips white. Abdomen above golden green, 1st ring and last ring, as well as dorsal spots black; the venter exhibits a white median stripe. Hindwings with a blue lustre and hyaline stripe in, below and behind the cell. Expanse of wings: 36 mm. Surinam.
- signatura.* **A. signatura** Wkr. (23 g) differs from all the species known by the orange abdomen. Thorax and wings are uniformly brown, the hindwing transparent in the disc. Palpal base, vertex, collar, and forehips spotted orange. West Indies (?).
- pydna.* **A. pydna** Druce. Anterior body dark brown, forehead and hips white; on the head, on each side a small, yellow spot. The abdomen is above brilliant metallic blue, laterally brown, underneath white. Forewings dark brown, the veins of the base yellowish; a broad, yellow oblique band crosses the forewing behind the middle from the costal margin to the proximal angle. Hindwings black with a hyaline stripe in the disc. Expanse of wings: 32 mm. Ecuador.

129. Genus: **Procalypta** Btlr.

Thorax and base of abdomen with thick, woolly hair. Veins on the forewings without any peculiarities; the costal margin of the hindwing is bent strongly convex before the middle; the cell is very long, the upper median and lower radial vein rise from the lower cell-angle, the middle radial above it. Only one beautiful, large species.

- subcyanea.* **P. subcyanea** Wkr. (23 g). The anterior body is black with white spots, the abdomen lustrous metallic blue, the two last segments above, the 4 last ones beneath deep carmine. The black forewings exhibit large, white, diaphanous spots in the cell-end and below the middle of the cell, and 2 below and above the upper radial. The hindwings being suffused with blue show hyaline spots in, below and behind the cell; the latter are absent in — subsp. **victorina** Druce (23 g) from Costa Rica and Panama. The nomenclatural type occurs in Mexico.

131. Genus: **Uraga** Wkr.

Siphon well-developed; 2nd palpal joint obliquely rising, the 3rd long and straightly porrect. Tibiae with short spurs. On the forewings, the upper radial rises far behind the upper cell-angle; the 3 lower subcostal veins are long-pedicelled, the 2nd subcostal vein from the upper cell-angle, the 1st freely from the cell. The cell of the hindwing is very long, the lower median vein comes about from the middle of the median, the upper one from below the lower cell-angle, from which both the lower radial veins rise.

- haemorrhoea.* **U. haemorrhoea** Wkr. (23 g). The head and the underside of the 3 last abdominal rings are carmine; thorax dark brown, the abdomen metallic blue. Forewings with a narrow, white, postdiseal oblique band bordered with yellow. Hindwings grey with a metallic blue lustre, in the disc transparent. Expanse of wings: 42 mm. Jamaica.
- rubricollis.* **U. rubricollis** Hmps. The body is brownish-black, on the abdomen above lustrous blue; palpal base and neck scarlet. Sides of forehead, hips and venter whitish. On the forewing, a white oblique band runs across the cell-end from the subcostal to the lower median vein. Hindwings suffused with metallic blue. Expanse of wings: 40 mm. Colombia.
- trifida.* **U. trifida** Dogn. Head and thorax brownish-black. Palpal base and border of the shoulder-covers scarlet; the front of the palpi, sides of the forehead, a central spot on the vertex, a dorsal line on the thorax

and the hips are white. The borders of the shoulders-covers, dorsal and lateral lines on the abdomen, as well as the venter are yellowish-white. Abdomen above with a blue lustre. Forewing in the basal half brownish-grey with darker veins, in and below the cell intermixed with orange scales, in the distal half brownish-black with 3 longish, light subapical spots between the upper radial and lowest subcostal vein. Hindwing in the costal half white, otherwise bluish-black. Expanse of wings: 32 mm. Peru.

131. Genus: **Gangamela** Wkr.

Distinguished from the preceding genus by the shorter, rising palpi, the abdomen being at the base above provided with rough hair, and lateral tubercles. On the forewings, the upper radial rises from the upper cell-angle, only the 1st subcostal vein comes freely from the cell. On the hindwings, the middle radial vein rises from above the lower cell-angle.

G. saturata Wkr. (23 g). Body black, front of the palpi, forehead, spots on the collar and shoulders, *saturata*, as well as stripes on the shoulder-covers and legs are white; narrow lateral lines and broad subdorsal stripes on the abdomen are likewise white. The basal half of the black forewing and an oblique spot behind the cell are yellow; the same is the case on the costal half of the hindwing; the proximal half, the distal margin and apex are black. Expanse of wings: 36 mm. Brazil.

G. ira Druce (26 i) has a black body, being spotted metallic blue on the head and thorax, with *ira*, metallic blue bands on the abdomen. Anterior femora striped white. Forewings black, with blue spots at the base of the proximal margin; in the submedian area, from the base to the margin, there extends a earmine longitudinal band bending down distally to the proximal angle. Hindwings with a red apical spot. Expanse of wings: 34 mm. Panama (Chiriqui).

132. Genus: **Euagra** Wkr.

Medium-sized species of a magnificent blue lustre, with hyaline spots on the wings, characterized by the lower radial veins rising on a long pedicle from the long, narrow cell of the hindwing; the upper radial of the forewing rises from the upper cell-angle.

E. caelestina Cr. (= *interclusa* Wkr.) (23 g). The large hyaline spot extends still beyond the upper *caelestina*, median vein, so that it is thus intersected by the vein. The first palpal joint, vertex and neck red. French Guiana, Amazon.

E. cerymica Druce (23 h) is recognizable by the earmine head. By the lower median vein rising *cerymica*, before the middle of the cell, the lower base of the large hyaline spot, lying on the said vein, almost becomes parallel to the proximal margin. Ecuador, Panama.

E. angelica Btlr. (23 h) greatly resembles *cerymica*, but has a black head, spotted metallic blue; *angelica*, the sides of the forehead are white. The ventral side of the abdomen is white. From Colombia and Ecuador.

E. delectans Schaus greatly approximates the preceding; is somewhat larger and different by the *delectans*, red palpal base, the forehead being isabel-coloured, the vertex and neck carmine; the abdomen is above of a deeper bluish-black. Expanse of wings: 34 mm. Costa Rica.

E. chica Hmps. (23 h). In this species the lower median vein of the forewing rises almost at the base, *chica*, whereby the hyaline spot grows extremely long, its lower side exactly parallel to the proximal margin. The head is black except the white forehead. Shoulder-covers and abdomen with white stripes. Peru and Bolivia.

E. haemanthus Wkr. (23 h). In this species and the two following ones, by the lower median vein *haemanthus*, only rising behind the middle of the cell, the hyaline spot is removed more towards the margin and is placed more obliquely; discernible from *azurea* by the carmine head and first palpal joint, the forehead being red, too. The fringes are dark. A common species, from Mexico, Guatemala, Costa Rica as far as Panama.

E. azurea Wkr. (23 h) has orange-yellow spots behind the eyes and in the neck, as well as on the *azurea*, palpi. The lower median vein rises behind the middle of the cell, the hyaline spot is, therefore, small. On vein 1 there is a white streak, as well as on the middle of the dorsum of the abdomen. Brazil (Santos).

E. klagesi Rothsch. The head is white, the vertex black; neck and the 2 first palpal joints carmine, *klagesi*, the terminal joint black. Thorax black with a blue lustre, abdomen of a brilliant deep blue, a dorsal line and the sides of the 1st ring lavender-grey; chest and venter white. Forewings black with a deep blue lustre. Subcostal area in the first fifth striped lavender-grey; in the cell there is a transparent bluish-white spot, a larger one between the median veins, and a smaller one above the upper median vein; fringes at the apex white. Hindwings like in *azurea*. Length of forewings: ♂ 21 mm, ♀ 17 mm. Surinam.

- caerulea.* **E. caerulea** Dogn. (23 i) is on the head quite black and blue without any red or orange. Forewings blackish-brown with a small, triangular, diaphanous spot above the base of the lower median vein. Hindwings with a metallic blue lustre and a hyaline stripe below the cell and above the base of the lower median vein. The body is unicolorously black, suffused with blue, the venter not white. Forehips whitish. Expanse of wings: 32 mm. Ecuador.
- splendida.* **E. splendida** Btlr. (23 h) exhibits, like most of the *Agyrta*-species, beside the hyaline spot of the basal half, yet a subapical hyaline spot between the radial veins. The first palpal joint, vertex and neck are red, the forehips and venter white. Brazil (Sa. Catharina).
- intercisa.* **E. intercisa** Btlr. (= auxo Wkr.) (23 i) differs from the following by the white venter and forehips. The hyaline spot in the lower part of the cell of the hindwing is absent.
- fenestra.* **E. fenestra** Wkr. (23 i) greatly resembles *intercisa*, and the hyaline spots on the forewings are the same. It is discernible by the black venter and hips; besides, the hyaline spot of the hindwing is much more extensive by another one being situate also in the lower part of the cell. Brazil.
- latera.* **E. latera** Druce (23 i) is the largest and most beautiful species, greatly deviating from the general type by only one large, oblique hyaline spot situate behind the middle, just cutting yet a piece off from the cell-apex. The forewings exhibit radiantly blue stripes at the costal margin and above vein 1. The hindwings are black with a blue lustre, without any hyaline spots. From Colombia, Ecuador, and Brazil.

133. Genus: **Mydromera** Btlr.

Only one, rather large species. The long cell of the hindwing sends forth the lower median vein long before the lower cell-angle, also the upper one rises before it, whereas the lower radial veins stand only on a short, common pedicle and rise from the corner. On the forewings, the upper radial vein rises from below the upper cell-angle.

- isthmia.* **M. isthmia** Fldr. (= notochloris Bsd., nolkeni Stgr.) (23 i). This beautiful, large species, being distributed from Mexico to the Amazon, is of a deep velvety black. The forewings exhibit distally an oblique hyaline spot and a metallic blue stripe above vein 1, the hindwings a narrow hyaline stripe below the cell as far as near the border. Fringes at the apex of the forewing and at the anal angle of the hindwing white. Palpi, forehead, vertex, collar, shoulder-covers and legs spotted metallic greenish-blue; abdomen with blue dorsal and lateral stripes, underneath white.

134. Genus: **Micragra** Hmps.

Distinguished from the preceding genus by the shorter palpi, broader and shorter forewings, on which the lower radial veins rise on a short pedicle; the upper one comes from the upper cell-angle or also from beneath (*ochrea*). On the forewings, the upper median vein comes from the same place with the two lower radials.

- sanguiceps.* **M. sanguiceps** Hmps. (23 i). Blackish-brown; 1st palpal joint, vertex and neck carmine, forehead blue, margined with white. Collar, shoulder-covers, metathorax, chest, and legs spotted metallic bluish-green, abdomen above suffused with bluish-green. Forewing at the base of the inner-marginal vein bluish-green. Between the median veins is a cream-coloured spot extending yet for some distance below the lower median vein; fringes at the apex white. Hindwings blackish-brown. Expanse of wings: 28 mm. Brazil (Lake Iguarazu).
- borealis.* **M. borealis** Rothsch. greatly resembles the preceding and differs at once by the entirely white underside of the body. Thorax lustrous green, only the terminal halves of the shoulder-covers are blackish-brown. The abdomen is above lustrous green with a broad, blackish-brown dorsal band except the entirely green 1st segment. On the forewings the creamy white spot extends to the proximal angle. The blackish-brown hindwings exhibit in the lower half of the wing an oval white spot, the inner-marginal vein is metallic-green. Length of forewings: 14 mm. Venezuela.
- ochrea.* **M. ochrea** Hmps. (23 k). Body ochreous-brownish, neck orange, anal tuft yellow. Forewings with darker-striped veins; in the middle of the cell and on the transverse vein dark dots, being connected by a streak on the discal fold; from the lower cell-angle an oblique, indistinct line runs to the proximal margin; behind an oblique, curved postmedian, in the marginal area, there are dark streaks in the cell-spaces. The thinly scaled hindwings are whitish, at the border blackish-brown. Expanse of wings: 30 mm. Brazil (Rio Grande). The species greatly resembles *Atyphopsis obscura* (21 b).

135. Genus: **Mevania** Wkr.

Distinguished from the preceding by the lower radial veins of the forewing rising unpetioled, whereas the upper one comes from far below the upper cell-angle; on the hindwings, the upper median vein comes from below the lower cell-angle which sends forth both the lower radial veins. Female antennae doubly short-combed.

M. quadricolor Wkr. (23 k). Blackish-brown; palpal base and neck orange; head and thorax spotted *quadricolor*. metallic blue. Abdomen with blue transverse bands, beneath whitish. The forewings are metallic green at the base; the centre is crossed by a broad, yellow transverse band. Hindwing with a yellow oblique spot from the costal centre to behind the lower cell-angle; base of the median blue. Expanse of wings: 36 mm. Venezuela; Ecuador.

136. Genus: **Paramevania** gen. nov.

It forms the transition between *Mevania* and *Parastatia*, to the latter of which it is closely allied in the veins. Siphon well developed. Palpi slender, erect, projecting beyond the vertex. Antennae doubly combed with rather short dents; tibiae with rather long spurs, base of abdomen roughly haired. On the forewings, the lower median vein rises from behind the middle of the median, the upper one before the lower cell-angle, from which the 2 lower radial veins proceed on very short pedicle. The upper radial vein comes from far below the upper cell-angle, the 1st subcostal freely from the cell. Cell of the hindwing rather long, the 1st median vein from below the lower cell-angle, the middle radial vein, being proximally strongly curved, above it. The subcostal vein rises before the upper cell-angle.

P. inconspicua spec. nov. (23 k) is a unicolorously dull greyish-brown insect. Neck, throat and *inconspicua*. base of palpi orange-yellow. The first abdominal rings above with a slight slate-blue lustre. At the cell-end, an entirely faded, darker median band crosses the forewing from the costa to the proximal margin. The hindwings are of a somewhat greyer tinge with a very feeble purple lustre. Expanse of wings: 29 mm. A ♂ from BANG-HAAS, the patria not being stated.

137. Genus: **Microgiton** Fldr.

Very near to *Mevania*; palpi longer and more slender, more porrect; tibiae with very short spurs. Female antennae doubly serrate-dentate. On the forewings, the upper median vein and the 2 lower radial veins are all separated. On the hindwings, the 1st median and the 3rd radial veins rise on a joint pedicle from the lower cell-angle, the middle radial vein proceeds above it.

M. submacula Wkr. (= *selene* Fldr.) (13 k). Blackish-brown; hips and venter whitish. Veins of the *submacula*. forewings striped yellowish. Hindwings light yellow, the distal and proximal margins broadly black. Expanse of wings: 30 mm. Venezuela; Colombia; Amazon.

138 Genus: **Hyparphara** Hmps.

Differs from the preceding merely by the uppermost radial vein of the forewing rising from the upper cell-angle. Male antennae doubly combed.

H. junctura Wkr. (= *cingulosus* Fldr.) (23 k). Body blackish-brown, anteriorly with single, light *junctura*. yellow hairs; forehead spotted white. The abdomen exhibits square, light yellow, small subdorsal spot; the venter is banded white. At the cell-end the forewing exhibits a yellow oblique spot. Hindwings with yellow stripe-shaped spots at the costa, in the cell and at the proximal margin. Expanse of wings: 34 mm. Colombia.

139. Genus: **Parastatia** Hmps.

Siphon well developed; the erect palpi reach the vertex; antennae doubly combed. Abdomen on the last segments laterally and at the end with hair-tufts. On the forewings, the 1st median vein and the two lower radials rise all separated. The upper radial comes from below the upper cell-angle; all the subcostal veins rise on a joint pedicle. On the hindwings, all the veins rise separated; the subcostal vein proceeds far before the upper cell-angle.

P. parnassia Möschl. (23 k) has a black body with a deep blue lustre. Front of the palpi, sides of *parnassia*. the forehead, throat and spots on the shoulders, chest, hips and legs white. The abdomen is spotted white above, laterally and sublaterally; the anal tuft carmine. Forewings hyaline with broad black margins, apical spot and discal band being fused with an inner-angular spot; in the broadly blackish-blue base of the proximal margin there is a whitish-blue spot. Hindwings hyaline with black veins, a black spot in the base of the cell, and a brightly lustrous blue border. Expanse of wings: 40 mm. Surinam.

140. Genus: **Agyrta** Hbn.

The species look like the *Euagra*-species and are discernible by the unpetioled course of the two lower radial veins of the hindwing. On the forewing, the lower radials do not rise from the same place, but separately, the upper one from below the upper cell-angle, the 3rd subcostal vein rising nearer to the margin than the 5th.

- dux.* **A. dux** Wkr. (= *aestiva* Blr., *phylla* Druce) (24 a) is one of the largest species, black with a deep blue lustre and large hyaline spots, one of which on the forewing extends from the base almost to the proximal angle. Palpal base and sides of the neck are carmine. Honduras, Guatemala, Panama, Venezuela, and Sa. Lucia, also from Santos. — In *superba* Druce the hyaline spot of the hindwing is narrower, the part in the cell being absent altogether.
- micilia.* **A. micilia** Cr. (24 a) is smaller than the preceding and the proximal hyaline spot is shortened, does not extend as far as the base, but only to a little behind the rise of the lower median vein; the subapical hyaline spot only extends down as far as the 3rd radial. Widely distributed, from Panama; Guiana; Brazil, Ecuador.
- chena.* **A. chena** Druce (23 k) has a black head; palpal base and vertex are carmine. The inner-marginal area of the forewing is blue, on vein 1 striped white. The hyaline spot comprises the lower cell-end, a narrow, small stripe below the lower median vein and a larger spot above it; a subapical hyaline spot is between the radial veins. From the Amazon. — The Bolivian form: **garleppi** Rothsch. (= ab. 1. *Hmps.*) is distinguished by somewhat larger hyaline spots, particularly the submedian spot extending to the base of the forewing, the light blue stripe on the inner-marginal vein being longer and broader, too.
- flavitineta.* **A. flavitineta** Hmps. (24 a), by the arrangement of the spots of the forewing, entirely resembles *chena garleppi*, but the spots are tinged yellow, the whole animal being larger and the hindwings of a more radiant light blue. Bolivia.
- auxo.* **A. auxo** L. (24 a). Black, suffused with blue. The 1st palpal joint and the vertex carmine; forehead white. Thorax and legs striped white. Abdomen with dorsal and lateral white stripes and with a white underside. Forewings black, below the base of the cell blue, the inner-marginal vein striped white. From the middle of the cell above the lower median vein to near the distal margin there extends a cuneiform, hyaline oblique spot; above it is an elliptic, white oblique spot. Hindwings at the proximal margin whitish with a hyaline stripe below the cell almost as far as the border. Expanse of wings: 36 mm. Venezuela; Surinam; Pará.
- bifasciata.* **A. bifasciata** Rothsch. Head blackish-brown, laterally white, vertex and neck scarlet. Thorax and abdomen blackish-brown, suffused with a lilac-blue, and with white median and lateral lines. Forewings sooty blackish-brown; the proximal half of the inner-marginal vein striped lavender-grey. The middle of the cell is crossed by an oblique hyaline band from the subcosta to two thirds of the length of the lower median vein; a similar band is behind the cell between the radial veins. Hindwings brownish-black, suffused with blue, with a median hyaline band. Length of forewings: 19 mm. British Guiana.
- klagesi.* **A. klagesi** Rothsch. Head blue, vertex and antennae black. Thorax velvety, on the collar and shoulder-covers lustrous bluish-green spots. Chest snow-white. Abdomen black, dorsally bluish-grey, laterally spotted bluish-green. Forewings velvety black, on the subcosta and inner-marginal vein towards the base striped bluish-green; at the cell-end there is a white, diaphanous, oblique spot extending from the subcosta to $\frac{3}{4}$ of the length of the lower median vein; at the apex a white spot. The ♀ has shorter and more obtuse wings. Length of forewings: ♂ 19 mm, ♀ 17.5 mm. Venezuela.
- abdominalis.* **A. abdominalis** Rothsch. Head and thorax black with white dots, abdomen suffused with blue, with greyish-white subdorsal lines, beneath white. Forewings black with a broad, lustrous blue longitudinal band above the inner-marginal vein, a hyaline spot in the cell and a larger one below the median; behind the cell is a hyaline oblique spot extending from the subcosta to the border on the 1st median vein. Hindwings black with a lustrous blue proximal margin and hyaline discal band. Length of forewings: ♂ 15 mm, ♀ 17 mm. Guiana; Venezuela.
- ockendeni.* **A. ockendeni** Rothsch. looks very much like *abdominalis* on the wings. The whole body, however, is above unicolorously lustrous blue; beneath the chest is sooty black, the venter white with a dark median band. The basal part of the forewing is more extensively radiant blue, the hindwings, beside the brilliantly metallic blue inner-marginal area, all over covered with blue. Length of forewings: 17 mm. Peru.
- semihyalina.* **A. semihyalina** Rothsch. Body sooty black, on the forehead and vertex, collar and shoulder-covers spotted white; abdomen with dorsal and sublateral white stripes. Forewings sooty black with a broad, semi-diaphanous white band above the inner-marginal vein to $\frac{3}{5}$ of its length, and an oblique, semi-diaphanous postdiscal spot extending from the subcosta to the upper median vein at the border. Hindwing black with a very broad, semi-diaphanous, white median band. Length of forewings: 16 mm. Amazon.
- monoplaga.* **A. monoplaga** Druce (24 a) is easily recognizable by the very large hyaline spot of the hindwing, filling up the distal two thirds of the cell and expanding above and below the lower median vein; there is no subapical hyaline spot. The hindwings are blue without any hyaline spots. Palpal base, throat, and vertex carmine. Ecuador.

A. pandemia Druce (24 b) resembles *monoplaga*, but it has a considerably smaller hyaline spot being *pandemia*. placed more towards the margin. The hindwing exhibits a discal hyaline spot. The head is black and white, not red. Amazon (Pará).

A. rubroanalis Rothsch. Body sooty black, suffused with blue; the last abdominal ring carmine with *rubroanalis*. a black anal tuft. The forewing is in the basal half hyaline with a lustrous blue costa and proximal margin; behind the cell there is a very large, hyaline oblique spot from the subcosta to the border as far as the upper median vein. Hindwings are not mentioned in the description of this species having remained unknown to me. Length of forewings: 17 mm. West Ecuador.

A. mathani Rothsch., unknown to me, according to the description, most exactly resembles *Cyanopepla mathani*. *chelidon* Druce. (23 b). Described from Colombia and Ecuador.

A. porphyria Cr. (= *cryptolenca* Wkr.) (24 a) is a large species with preponderantly black forewings *porphyria*. and a greenish-blue stripe being usually broadly interrupted by black in the middle, in the submedian fold. The hyaline spot outside on the 3rd radial is divided in two parts by the black ground-colour entering it in a tooth-like fashion. The entirely black hindwings are lustrous blue on the median and its veins; between the median veins there are indistinct, whitish, blurred spots. From Venezuela, Guiana, Brazil, Bolivia. — **rothschildi** *rothschildi*. *subsp. nov.* (24 b) is distinguished by the green submedian stripe being very broad and extending as far as the margin; on the hindwings there appear distinct hyaline spots below the median. Before me from Peru (Tarapoto).

A. conspicua Schaus. Head earmine, as well as the palpi with a black terminal joint. Body above *conspicua*. dark blue; above, on the abdomen, a whitish dorsal line, the venter dusted with whitish. Forehips white, wings bluish-black, at the costa and proximal margin of a brilliant metallic blue. Forewing with a large hyaline area in and below the cell, extending near the distal margin. Hindwing with a long hyaline stripe from the base above and below the median as far as near the distal margin. Expanse of wings: 45 mm. Costa Rica.

A. birchi Rothsch. Head white, on the vertex black. Thorax brownish-black; abdomen blue with *birchi*. an obsolete, interrupted, white median line. Forewing velvety black with a white oblique stripe through the middle from the subcosta towards the proximal margin as far as the middle between the median and inner-marginal vein. Fringes at the apex white. Hindwing velvety black with white fringes at the apex and a broad, drab proximal margin. Length of forewings: 14 mm. Minas Geraes. — **borealis** Rothsch. is larger, and the *borealis*. proximal margin of the hindwing is white. Length of forewings: 16 mm. Venezuela. — **pumila** Rothsch. from *pumila*. the Rio Madeira is smaller, with narrower and more pointed wings, the proximal margin of the hindwing being likewise white. Length of forewings: 12 mm.

A. pseudodelphire Rothsch. Head and thorax blackish-brown, shoulder-covers striped white. Abdomen *pseudo-* above brown, suffused with blue, beneath with sublateral white stripes. Chest yellow-reddish. The forewings *delphire*. are purple brown, on the subcosta towards the base striped white, with a white, postcellular oblique band from the subcosta to the proximal angle. Hindwings black with a blue lustre and a white discal band from the base as far as half the length of the lower median vein. The ♀ has shorter and much broader wings, a white forehead and inner-marginal vein of the forewing. Length of forewings: ♂ 20 mm, ♀ 18 mm. Venezuela.

A. buchwaldi Rothsch. This species having remained unknown to me, according to the description *buchwaldi*. exactly resembles *Cacostatia flaviventralis* (23 c), only a little smaller. Described from Colombia, Ecuador, Bolivia.

A. acutipennis Rothsch. greatly resembles *nitens*, but the apex of the forewing is extended into a *acutipennis*. sharp point. Head, thorax, and abdomen are above purple blue; chest sooty black, venter white. Wings marked as in the preceding, but the postdiscal hyaline spot extends farther down as far as the lower median vein. Length of forewings: 21 mm. Colombia (Bogotá).

A. nitens Rothsch. Body of a brilliant deep blue; a spot on the forehead, the chest and venter are *nitens*. white. Forewing of a brilliant deep blue, at the base above the inner-marginal vein and below the subcostal hyaline, a hyaline oblique spot extends from the subcosta at the cell-end as far as the border. Hindwings hyaline with a broad distal margin and veins of a brilliant blue colour. The ♀ is blacker on the dark places of the wings, suffused with blue. Length of forewings: ♂ 20 mm, ♀ 19 mm. Colombia; Ecuador and Peru.

A. germana Rothsch., at first sight greatly resembles *nitens*, but the dark margin of the hindwing *germana*. extends at the proximal margin farther towards the base and is broader on the median. The species is smaller, with narrower wings and may immediately be distinguished by white spots on the collar and base of the shoulder-covers, as well as by subdorsal and sublateral, lavender-grey lines on the abdomen. From Surinam and Venezuela.

A. pulchiformis Rothsch. Head black, forehead spotted white; thorax and abdomen blue; shoulder- *pulchri-* covers light bluish-grey; chest and venter greyish-white. Forewings black with a blue lustre; above the inner- *formis*. marginal vein a large hyaline spot extends as far as $\frac{4}{5}$ of its length; behind the cell there is a hyaline oblique spot from the subcosta to the margin on the lower radial. Hindwings hyaline with a black margin suffused with blue, being very much broader at the proximal margin and apex. Length of forewings: 14 mm. Peru.

- vitrea*. **A. vitrea** *Schaus* (24 b) on the forewing has two extremely large hyaline spots, so that only the margins, an apical spot and an oblique band from the costal margin across the cell-end and along the upper median vein as far as the margin remain black; the hindwings are entirely hyaline with black veins and margins with a blue lustre. The first palpal joint and the neck are carmine. The blue abdomen is dorsally striped white, underneath entirely white like the hips. Described from Costa Rica, a couple is before me also from Peru (Marcapata), thus apparently widely distributed.
- albisparsa*. **A. albisparsa** *Hmps.* (24 b) is distinguished by a particularly narrow shape of the wings and by the black forewings being peculiarly densely strewn with white scales; in some places these scales are strewn more densely, so that there appear 3 indistinct transverse lines. The hyaline spot is strewn with brownish. The neck is orange. Sa. Catharina.
- varuna*. **A. varuna** *Druce*. Head and thorax black, neck and palpi carmine, shaft of antennae white, the teeth of the comb black. Collar black, bordered with white. Abdomen above metallic blue, beneath white; across the thorax and abdomen extends a white dorsal stripe. Forewing black with a semi-diaphanous, white band from the base as far as the cell-end; near the apex a white spot. Hindwings yellowish, at the apex and distal margin black, with a brilliant blue lustre. Expanse of wings: 40 mm. Peru.
- lacteicolor*. **A. lacteicolor** *Rothsch.*, according to the description, greatly resembles *varuna*. Head black, laterally white; palpal base and neck carmine. Antennae white with black serrations. Thorax sooty brown, abdomen blue, both with a white median band. Underside white. Forewings black; a small, semi-diaphanous, longitudinal spot in the cell, a larger one at the basal half of the lower median vein are cream-coloured; on each side of the middle radial a semi-diaphanous, white spot. The wings are in the basal halves reddish cream-coloured, distally black, suffused with blue. Length of forewings: 23 mm. Peru.

141. Genus: **Phara** *Wkr.*

Few smaller species being above all distinguished by long, straightly porrect palpi with the terminal joint turned downward. On the forewings, the upper median vein rises close at the lower cell-angle, the lower radial veins from it, the 1st radial from the upper cell-angle, the 1st subcostal vein from the cell. On the hindwings, the long cell sends forth the upper median vein and the lower radial veins from its lower cell-angle, the 1st radial and the subcostal vein from the upper one.

- flavicosta*. **Ph. flavicosta** *H.-Schäff.* (24 b) has a black body with orange-yellow shoulder-covers and spots at the penultimate abdominal ring; $\frac{3}{4}$ of the costal margin of the brown forewings are orange-yellow, too. The transparent hindwings are broadly bordered with black; the proximal margin exhibits a tuft of long, light brown hair. Brazil (São Paulo; Rio Grande do Sul). — **missionum** *Jørgensen* from Argentina has the two penultimate abdominal rings entirely whitish-yellow. Taken in September on blossoming Eupatorium, in day-time.
- sanguipalpis*. **Ph. sanguipalpis** *Dogn.* Vertex, neck and palpi scarlet except the black terminal joint; forehead black, with metallic green spots. The other part of the body is black, suffused with a lustrous bluish-green on the abdomen, hips and femora. Forewings brownish-black, hindwings bluish-black. Expanse of wings: 27 mm. Peru.
- trivittata*. **Ph. trivittata** *Wkr.* (24 c) is blackish-brown on the anterior body and forewings; palpal base and hindhead carmine. Abdomen lustrous blue with a white dorsal stripe like on the metathorax; beginning from the 4th ring with white lateral stripes, and the 3 last rings underneath white. On the forewing, in the cell-end, there is a small, square, white spot, and below the cell between the lower radial veins a larger, longish one. Costal and proximal margin towards the base white. Hindwings black, with a bright blue lustre with a large, diaphanous white discal spot extending as far as the base. Expanse of wings: 40 mm. Patria unknown.
- nycthemeroides*. **Ph. nycthemeroides** *Wkr.* (24 c) greatly resembles the preceding; distinguished by the underside of the hindwings, the costal margin of which is white from the base to the middle. Patria unknown. The original example lacks the abdomen.

142. Genus: **Ptychotrichus** *Schaus.*

Only 2 large species of a robust structure with long, narrow forewings with a very oblique distal margin and small, triangular hindwings. Base of abdomen roughly haired. Proboscis well-developed; the erect palpi extend beyond the vertex. The male antennae doubly short-combed. On the forewings, both the lower radial veins are petioled; all the subcostal veins are on a joint pedicle. On the hindwings, the lowest radial vein is absent; the 1st median vein and the middle radial come from the same place from the lower cell-angle. In the ♂ the proximal angle is pointed, an inner-marginal fold contains a tuft of long hair.

P. zeus *Schaus* (24 c). Head and thorax blackish-brown with an orange-yellow neck; forehips white; *zeus*. on the metathorax an orange dot. Abdomen black with blue subdorsal spots and single orange ring-indentations. The 3rd and 4th rings are underneath banded white, the 2 next ones sublaterally spotted. Forewings blackish-brown with lighter veins, dull olive-yellow dentate lines before the middle and before the margin with very long, sharp teeth; in the middle of the cell there is a triangular, at the cell-end a square, olive-grey spot; behind the cell 2 similar ones above and below the 1st radial. Hindwings diaphanous white with black veins and a deep bluish-black, broad border. The inner-marginal hair-tufts are ochreous-yellow. Expanse of wings: 54 mm. Venezuela.

P. elongata *Schaus*. Anterior body brown, shoulder-covers striped orange; a reddish olive-yellow *elongata*. stripe extends from the base of the antennae to the shoulders. Abdomen orange, with black bands, the last ring all black; the first 4 rings exhibit above a broad, brown dorsal band narrowed on the others to an interrupted dorsal line; underside white. Forewings light grey; costa, apex and proximal margin dark brownish-grey, the veins light reddish-brown. In the middle, in and below the cell there is a large, round, dark brownish-grey spot bordered with whitish-grey; at the cell-end there is a similar, irregular spot; a similar line extends from the subcosta towards the 1st median vein and borders on the darker apex. Before the margin a dentate line above the middle radial; in the marginal area between the veins there are darker streaks being bordered with an isabel-colour below R². Hindwings hyaline, veins and margins black. Expanse of wings: 43 mm. Brazil (Rio de Janeiro).

143. Genus: **Delphyre** *Wkr.*

Rather large, mostly dark coloured species. Cell of the hindwing very long, the lower median vein rises from below the cell-angle sending forth the upper median vein and the middle radial, whereas the upper radial is absent. A costal vein may occasionally be present, though only traceably so.

D. hebes *Wkr.* (*tristis* *Schaus*). Pale fawn-coloured; hindwings blackish with a light brick-coloured *hebes*. costal margin; the species is rather small. Described from Honduras.

D. brunnea *Druce* (24 c) is dark red-brown on the body and forewings; palpi in front and chest grey. *brunnea*. The forewings show traces of darker, undulate, transverse lines before and behind the middle and a discal luna. Hindwings blackish-brown, in the disc hyaline. Expanse of wings: 30 mm. Brazil (Espiritu Santo).

D. rubricincta *Hmps.* (24 c) has whitish, in some places brownish forewings, with black spots; the *rubricincta*. hindwings, being hyaline in the disc, are bordered with black. Anterior body greyish-brown; spotted black, hindhead with 2 orange spots. Abdomen above blackish-brown, curled carmine, venter with whitish bands. Panama.

D. minuta *Möschl.* (24 d). Head and thorax grey, spotted black, the neck and abdomen above carmine, *minuta*. underneath white; the last ring black. Forewings grey, quite similarly arranged as in the preceding, spotted black. Hindwings hyaline with black veins and margins. Expanse of wings: 26 mm. Venezuela; Surinam. — *Subsp. nov. extensa* (= subsp. I. *Hmps.*) from Bolivia (Rio Songo) has much more extensively black-spotted *extensa*. forewings.

D. maculosa *Hmps.* (24 c). Head grey, palpi, antennae and a spot on the vertex are black, the hindhead *maculosa*. orange. Thorax black, collar and shoulder-covers grey. Legs grey and black with yellow hips. The abdomen is yellow, on the first 4 rings with large, coherent, black dorsal spots, and on the 2 next ones with smaller ones; the 2 last rings are black with a grey anal tuft. Forewings greyish-brown with black spots arranged similarly as in *rubricincta*. Hindwings brownish-black, at the base whitish. Expanse of wings: 40 mm. Amazon (Pará).

D. roseiceps *Dogn.* (24 c) has whitish wings, slightly tinged brownish at the margins, with slightly *roseiceps*. brownish veins and numerous black spots; head and thorax pale grey, spotted black, the neck and base of the collar rosy-carmine. Abdomen carmine with a black lateral line and black anal apex, on the dorsum of the two first segments yellowish; underneath, inclusive of the hips, pale rosy. French Guiana.

D. pusilla *Btlr.* (? *dares* *Cr.*) (24 d) looks very much like *roseiceps* on the wings, but it is considerably *pusilla*. smaller and its abdomen is above entirely blackish-brown, only beneath rosy. The neck shows two carmine spots. Anal hairing in the ♂ white. — In **flaviventris** *form. nov.* (24 d) the ventral side as well as the spots on *flaviventris*. the neck are yellow. Distributed from Guiana to the Amazon.

D. discalis *Druce* is on the body above unicolorously black, the collar spotted red at the base, *discalis*. underneath white. Forewings blackish diaphanous, the veins, a large spot at the cell-end, the apex, distal and proximal margin black; hindwings hyaline, broadly bordered with black. Expanse of wings: 40 mm. Venezuela.

D. albiventus *Druce* (24 e) is easily recognizable by the brown forewings with a white, transparent *albiventus*. oblique spot at the cell-end; fringes at the apex white. The brown hindwings are semi-diaphanous whitish towards the proximal margin. The abdomen, being above blue, is white on the ventral side. Brazil (Amazon; Minas Geraes; Rio de Janeiro).

- aelytioides*. **D. aelytioides** *Hmps.* Blackish-brown; palpal base, forehead, sides of the forehips and transverse bands on the ventral side are yellow. The last abdominal rings above with metallie blue bands. Forewings with lighter veins and an orange spot behind the costal centre, from which a yellowish oblique band runs to the proximal angle. Expanse of wings: 36 mm. Cayenne.
- varians*. **D. varians** *Hmps.* (24 e) is larger than the preceding, on the body quite unicolorously blackish-brown, only the posterior abdominal segments blue, on the others lateral and sublateral spots. Forewings marked as in *aelytioides*, but without any lighter veins. Hindwing at the base diaphanous. The ♂ has very broad forewings and small hindwings, the latter with a strongly arehed costal margin covering an unsealed patch on the under surface of the forewings. Expanse of wings: 40 mm. Amazon. — *ab. nov. reducta* (= *ab. 1. Hmps.*) exhibits only a small orange spot at the upper cell-angle.
- rufiventris*. **D. rufiventris** *Schaus* (24 d) is above brown, the hindhead and collar spotted earmine, the 5th to 7th abdominal rings narrowly bordered with red; the venter is all red, so are the forehips and base of the palpi. The hindwings are of a blackish colour with a blue lustre, in the disc semi-diaphanous. From Mexico (Misantla, Jalapa). — *subsp. hampsoni* *Rothsch.* from Peru has a drab ground-colour, the red being more brick-red; the veins of the forewings are prominently darker, and some of the cell-spaces in the basal half and behind the cell *orientalis*. are more thinly scaled. — f. **orientalis** *Rothsch.* from the Rio Madeira is smaller, of a more brownish-grey colour, *meridensis*. and f. **meridensis** *Rothsch.* from Venezuela is distinguished by a large, yellowish-grey, reniform discal spot; the hindwings are not lustrous blue, and the abdomen is sooty black.
- pyroperas*. **D. pyroperas** *Hmps.* (24 d). Head and thorax light red-brown, on the hindhead and shoulders spotted earmine; palpal base and hips rosy. Abdomen above blackish-brown, the 4 last rings earmine, bordered with black, beneath all red. Forewings light red-brown with darker veins, cellular and submedian folds; the discal spot and apex faded darker. Hindwings blackish-brown, in the disc hyaline. Expanse of wings: 42 mm. Occurring from Brazil (São Paulo, Rio Grande do Sul) as far as Paraguay.
- pyrozona*. **D. pyrozona** *Druce* is coloured black on the body above; the abdomen is yellow at the base, on the 4th to 6th rings of a brilliant red; the underside is rosy. Forewings blackish brown with yellowish veins; a spot in the cell and 4 near the apex greyish-white of varying distinctness. Hindwings hyaline with a broad black margin. Expanse of wings: 32 mm. Venezuela.
- dizona*. **D. dizona** *Druce* (24 d) is blackish-brown on the body and wings; the first palpal joint and two spots on the hindhead are carmine; hips and ventral side white. The forewing shows oblique, transparent spots, one before the cell-end, one behind it. The hyaline hindwings exhibit a black margin. French Guiana. — Occurs *aurantiiceps*. also with an orange-yellow neck and palpal base: **aurantiiceps** *form. nov.*
- suffusa*. **D. suffusa** *Lathy* (24 e) looks rather like *dizona* above, but it is larger and easily discernible by metallie blue subdorsal spots on the abdomen and earmine forehips. Distributed from French Guiana as far as Santos.
- macella*. **D. macella** *Dogn.* (24 e) is a smaller species which is easily recognized by the peculiar hindwings: the very broad inner-marginal area being semi-diaphanous whitish with a black border and a black stripe along vein 1 as far as the base. The costal part is hyaline, of an intense iridescence. The brown forewings with lighter veins and indistinct transverse lines exhibit hyaline spots in the cell and behind it. The anterior body is brown, in the neck spotted orange. The abdomen is above light carmine, on the 2 first segments dorsally yellowish-white, the two last ones black with a rosy spot on the last ring. Venter and hips white. French Guiana.
- lemoulti*. **D. lemoulti** *spec. nov.* (24 f). Body blackish-brown, abdomen posteriorly with a faint greenish-blue lustre, neck, throat, palpal base, hips and 2 spots on the metathorax light ochreous-yellow; venter somewhat lighter olive-grey. The dark-brown forewings are similarly marked as in *macella*: veins and a spotted ante-marginal line indistinctly lighter yellowish-grey, a minute spot in the cell, 4 similar ones behind the cell, the two lower ones of which are situate more towards the margin, and a blurred spot in the submedian space diaphanous. The hindwings are hyaline in the basal part, in the marginal half blackish-brown. One ♂ from French Guiana (Nouveau Chantier). Type in the Coll. DRAUDT.
- subapicalis*. **D. subapicalis** *Jones*. Smoky black; palpi at the base, head and chest orange, collar tinted orange, shoulder-covers bordered with a light brown. Ventral side yellowish-white. Forewings smoky-blackish with somewhat lighter veins; near the apex there is a large white spot, extending from the costa as far as below the 3rd radial. Hindwings black, in the disc diaphanous. Expanse of wings: 39 mm. Paraná.
- atava*. **D. atava** *Druce* (24 f). A large species with dark brown forewings; the hindwings are hyaline with a black margin. Thorax dark brown; forehips red, as well as two spots on the hindhead. Abdomen black, with subdorsal blue spots. Panama.
- nigra*. **D. nigra** *Schaus* is black on the body, the hindhead spotted blue; abdomen with yellow transverse bands, growing particularly conspicuous on the sides, as they are above covered by long black hairy scales.

Forewings black, at the base a blue dot. Hindwings black, towards the base thinly sealed, whitish. Expanse of wings: 38 mm. Chiriqui. The following species may possibly belong to it as a subspecies.

D. spreta *spec. nov.* (24 e) greatly reminds us of certain *Opharus*-species, particularly *procroides* Wkr.: *spretu*. the forewings are brown, towards the base of a somewhat more olive-yellowish tinge with darker veins and a diffuse darkening at the cell-end; the blackish hindwings are diaphanous in and below the cell. The anterior body is blackish brown, on the vertex and at the bases of the wings spotted silvery blue; the metathorax exhibits a white spot. The abdomen is above black, beginning from the second segment with lateral, orange-yellow bands, from the 4th ring these spots are united to complete belts across the dorsum. Described according to 3 ♂♂ from Colombia (January 1910 Cañon del Tolima; May 09 San Antonio — captured by the light of a lamp — and from the Upper Rio Negro: FASSL).

D. flaviventralis *Hmps.* Brownish-black; the palpal base, 2 small spots in the neck and a broad median stripe on the venter orange. The forewings show a whitish oblique band across the cell-end from the subcosta to the submedian fold, another one behind it between the lowest subcostal vein and the upper median vein. Hindwings black with a hyaline disc. Expanse of wings: 45 mm. Venezuela. *flaviventralis*.

D. monotona *Dyar* greatly approximates *flaviceps*, but it is smaller, much less distinctly marked, and the border of the hindwing is considerably narrower; the forehead is greyish-brown. Mexico (Santa Rosa). *monotona*.

D. testacea *Druce* (24 f) has brown forewings with a lighter spot being very faintly indicated by a thinner scaling in and below the cell and a similar oblique band behind the cell which is beneath much more distinct. Hindwings diaphanous with a broad, black margin. The body is greyish-brown, the first palpal joint and vertex olive-yellow; forehips and venter orange. Guatemala and Panama. *testacea*.

D. klagesi *Rothsch.* greatly resembles *testacea*, but it is darker and more distinctly marked. The body is brownish-grey with a blue lustre. The basal palpal joint and the vertex orange, not olive-yellow. Forewings dark brownish-grey; the proximal spot is only situate below the median. Hindwings bluish-black, in the disc hyaline. The ♀ has an entirely orange-yellow head and lighter, yellowish grey-brown forewings. Length of forewings: 22 mm. Guiana; Venezuela. *klagesi*.

D. infraalba *Rothsch.* Anterior body above blackish brown, in the neck and minute spots on the collar carmine. Abdomen above sooty black with a dark blue lustre. The underside is white. Forewings blackish-brown, in the basal half subcostally with hyaline stripes; an indistinct, postdiscal transverse band whitish diaphanous. Hindwings black with a hyaline discal band. The ♀ is similar, but more sooty brownish-grey. Length of forewings: 19 mm. Venezuela; Cayenne. *infraalba*.

D. rhodocrypta *Druce.* The anterior body is above greyish-brown; spots on the collar and the upperside of the abdomen are black, as well as the legs. The whole underside is yellowish-white. Forewings dark brown, in the cell and near the apex spotted greyish white. Hindwings hyaline, broadly bordered with black. Expanse of wings: 32 mm. Venezuela. *rhodocrypta*.

D. tetilla *Dogn.* (= *elegans* *Lathy*, *bimaculata* *Rothsch.*) (24 e) is a pretty, very deviating species: *tetilla*. The deep brownish-black forewings exhibit a hyaline spot in the cell, another one behind it; the hyaline hindwings, being traversed by lustrous blue veins, are bordered with black; underneath with an intense blue lustre. Head black, spotted white, neck carmine; thorax blackish-brown, hips white. Abdomen above metallic blue, underneath white. Colombia; Ecuador; Peru (Macrapata). Probably also (*Napata*) *boettgeri* *Druce* belongs to it as a synonym (vide p. 141).

144. Genus: **Heliura** *Btlr.*

Extremely near to the next genus, distinguished chiefly by the middle radial of the hindwing rising from above the lower cell-angle, and by the absence of the hairing on the abdominal base and sides. The upper median vein of the forewing always rises distinctly below the cell-angle, the lower radial veins from it or also on a short pedicle, the upper radial distinctly from below the upper cell-angle. The cell of the hindwing is long, the upper median vein with the lower radial come from the lower cell-angle always distinctly petioled, the 1st radial and the subcostal vein rise unpetioled from the upper cell-angle. The species partly greatly resemble *Eucereon*-species, a small part of them, however, looks most remarkably different.

H. rhodophila *Wkr.* (= *tetragramma* var. *Wkr.*, *pyrrhosoma* *Btlr.*, *solicauda* *Btlr.*) (24 f). Head and thorax brown, with brick-red spots and stripes; the red abdomen exhibits black lateral lines, the first and last segment are black. The brownish forewings with brick-red veins are spotted black and exhibit hyaline *rhodophila*.

spots in and below the cell, as well as 4 behind it, the two lower ones of which are placed more towards the margin. The hyaline hindwings are bordered with black, the anal-angular appendage being black. Hips and femora are ochreous-yellow, the legs black. Honduras; Costa Rica; Guiana; Pará.

tetra-
gramma. **H. tetragramma** *Wkr.* (24 f) greatly resembles the preceding, and is distinguished by its brick-red chest, hips, femora and ventral side, and similarly spotted legs; the postdiscal hyaline spots exhibit blackish-brown dots. Amazon.

assimilis. **H. assimilis** *Rothsch.* greatly approximates *tetragramma*, and differs by the white ventral side and hips, by black, not orange-red veins on the forewings; the red colour of the abdomen is more brilliant carmine, in the basal half blackish-brown. Described from Peru.

fulvipicta. **H. fulvipicta** *Kaye* is distinguished by the very long, narrow shape of the wings. The head is black, behind the eyes spotted yellow; thorax and shoulder-covers blackish-brown. Abdomen black with a yellow basal spot; on the ventral side of the 3rd and 4th rings there are large, white spots. Forewings brownish with blackish-brown veins and transverse bands in the disc and at the apex, the basal area being black with a golden yellow spot. Hindwings hyaline with a broad black border. Expanse of wing: 35 mm. British-Guiana.

elongata. **H. elongata** *Rothsch.* is unknown to me and may perhaps be synonymous with the preceding. The description is almost the same, but there are yet some yellow olive-grey spots mentioned on the thorax, and the posterior transverse band of the forewing is not denoted as apical, but as „postmedian“. Described from Venezuela.

umbrimacula. **H. umbrimacula** *Schaus* perhaps also belongs to the preceding. Body black, neck orange-red; on the metathorax there is a yellow spot; the forehips and a spot in the middle of the venter are white. The forewings are reddish olive-yellow with black veins; behind the middle, from the costal margin near to the proximal angle, there runs a broad, black nebulous stripe. The apex is broadly black, at the border with small spots of the darkened ground-colour in it; the costal base is spotted orange. The hindwings are white in the basal halves with black veins, distally black. Expanse of wings: 31 mm. French Guiana.

dolens. **H. dolens** *Schaus* is black on the body, with a blue lustre on the shoulder-covers and abdomen, in the neck orange-haired; the forehips and the first ventral rings are yellow-reddish. The forewings are dull black with velvety black nebulous stripes before and in the middle, subapically and antemarginally between the lower median and middle radial vein. Hindwings hyaline with a broad black margin. Expanse of wings: 27 mm. Venezuela.

postflavida. **H. postflavida** *Rothsch.* is larger than *dolens*, and the 2 last abdominal rings are orange, not black. The forewings are comparatively somewhat broader, otherwise similarly coloured and marked. Venezuela.

fumata. **H. fumata** *Rothsch.* This species has been established according to 2 much flown ♂♂ from Ecuador and Peru. The body is sooty brownish-black, posteriorly with a blue lustre, on the collar carmine spots. The abdomen exhibits beneath two white bands. Forewings sooty brown, the hindwings sooty black, with 2 whitish longitudinal spots in the inner-marginal area. Length of forewings: 20 mm.

fuliginosa. **H. fuliginosa** *Rothsch.* is sooty black on the whole body above and underneath. The forewings are more grey, in the discal area between the veins thinly scaled. Hindwings hyaline with a black margin, being spottedly expanded at the proximal angle. Length of forewings: 16 mm. Peru.

hecale. **H. hecale** *Schaus* is blackish-brown on the body, at the sides of the abdomen with metallic blue spots; 2 spots in the neck, and the hips are carmine. Forewings blackish-brown, in the disc in the cellular spaces thinly scaled, so that a hyaline, round, discal spot is produced. Hindwings hyaline, veins and margins broadly black. Expanse of wings: 42 mm. Peru.

caeruleocephala. **H. caeruleocephala** *Rothsch.* Head lustrous blue; thorax metallic blue and yellowish. On the collar there is a carmine spot; the shoulder-covers are brown with lighter stripes. Abdomen of a brilliant metallic blue, on the 3 first rings above with long black hair. The forewings are of a wooden brown with dark brown veins, the hindwings black with a blue lustre, the cellular spaces in the disc diaphanous grey. Length of forewings: 20 mm. Peru.

emerentia. **H. emerentia** *Dogn.* (24 g) resembles *Delphyre tetilla*, but the hyaline spots are differently distributed: the proximal one is situated below the middle of the cell; the head is all black, so is the neck, and not red, otherwise all is the same. Described from Ecuador (Loja), before me also from Colombia from the Upper Rio Negro, 800 m.

lemoulti. **H. lemoulti** *Rothsch.* greatly resembles *Delphyre suffusa*, but the forewings are not marked so speckled. The body is blackish-brown; chest and base of hips, as well as 2 small spots in the neck are carmine-rosy. The abdomen is laterally spotted or striped bluish-green. The forewings are blackish-brown with an indistinct

brownish-grey spot in the cell and a similar one behind it. Hindwings diaphanous greyish-white with an irregular, broad, black margin. Length of forewings: 20 mm. Cayenne.

H. viridicingulata Rothsch. Head and antennae are black, with white dots; thorax brownish-black, on the collar a white dot. Abdomen black with metallic green rings interrupted above. Forewings brownish-black, below the median a hyaline stripe, and behind the cell a broad, hyaline oblique band extending from the subcosta to the uppermost median vein. Hindwings hyaline, veins and distal margin black in an irregular extent. Length of forewings: 15 mm. Rio Toro. *viridicingulata*.

H. phaeosoma Druce (24 g) looks on the wings exactly like *rhodophila*, but the abdomen is above one-coloured black, below white, and the hindwings also in the ♂ have the normal shape without the anal angle being produced; hindhead and neck reddish-brown. Venezuela; French Guiana (Nouveau Chantier). *phaeosoma*.

H. klagesi Rothsch. resembles the preceding, but the underside is not white, but yellowish-rosy, the veins of the forewings are not red, but olive-brown, and the transparent basal part of the hindwing is not so distinctly defined towards the black distal margin. Venezuela. — *subsp. meridionalis* Rothsch. is a much larger and darker form from Suriman to Peru. *klagesi*. *meridionalis*.

H. distincta Rothsch. is on the head and thorax above olive-brownish, beneath yellow and rosy. The first two thirds of the abdomen are black, at the base above with a minute orange spot, the rest is sooty grey. The forewings are olive-brown with yellowish-grey veins, some small costal spots, and a double row of small, antemarginal sagittal spots. An indistinct, antemedian transverse band and a distinctly postmedian one from the costa to the upper median vein are whitish olive, with a rosy hue. Hindwings velvety black with a blue lustre, in the middle of the basal area with a large, white, semi-hyaline spot. Length of forewings: 19 mm. San Antonio (Rio Madeira). *distincta*.

H. thysbe Möschl. (24f) is blackish-brown on the body; the vertex and tips of the shoulder-covers are white. The 3 last abdominal rings exhibit large, carmine, dorsal spots with black pupils. Forewings white with numerous black spots. Hindwings in the basal halves white, veins and distal halves blackish. Expanse of wings: 36 mm. Surinam. *thysbe*.

H. ockendeni Rothsch. The head is black, on the vertex yellowish-grey, in the neck golden-yellow; collar black, anteriorly yellowish-grey, thorax yellowish-grey, striped and margined with black. The 4 first abdominal rings are above black, the 3 next ones orange, the last again black with a yellow-reddish, small spot; beneath the whole body is yellow-reddish. Forewings white, at the margins and veins yellow-reddish; from a subbasal, black transverse band there proceed short, black streaks along the costa and veins; behind it black spots subcostally and in the cell; an irregular, sooty black discal band extends from the costal margin to the proximal margin, a similar, postmedian one from the costa to the lower radial vein; before the margin a series of spots. Hindwings diaphanous greyish-white, the margin broad black, at the proximal margin drab. Length of forewings: 17 mm. Peru. *ockendeni*.

H. rubrocincta Rothsch. Head and antennae brown; thorax yellowish olive-brown, with brownish-black spots and stripes. Abdomen above sooty black, the 4th to 6th rings scarlet; the whole underside is yellowish rosy. Forewings, yellowish olive-grey with a number of sooty-brown stripes and spots being more or less confluent in the median area. Hindwings in the basal third diaphanous white, distally velvety black. Length of forewings: 17 mm. Venezuela. *rubrocincta*.

H. rufipes Rothsch. Head yellowish brownish-grey, with black spots, in the neck carmine-rosy; thorax olive-grey with dull brown spots, the shoulder-covers with yellow stripes. Abdomen light carmine-rosy, curled black, beneath unicolorously pale rosy. Legs rosy. Forewings grey with yellow veins, in the basal third with a number of black, yellow-ringed spots; the disc is traversed by an irregular, broad, sooty brownish-black transverse band, behind it a similar band from the costa to the middle radial; an antemarginal series of blackish-brown spots. Hindwings sooty black, in the disc diaphanous white. Length of forewings: 21 mm. Peru. *rufipes*.

H. balia Hmps. (24 g) has a greyish-brownish, darker spotted head and thorax; neck orange. Abdomen red with a black anal apex. Forewings white with blackish-brown spots, hindwings semi-diaphanous white with a greyish-brownish, narrow border. Honduras; Costa Rica (San Carlos). *balia*.

H. griseipuncta Rothsch. is smaller than *balium* and differs otherwise by its carmine neck and light reddish-yellow ventral side, the chest being scarlet-rosy. Length of forewings: 13 mm. British Guiana. *griseipuncta*.

H. zonata Druce (24 f) approximates *griseipuncta*. The spots of the forewing are compressed to 3 transverse bands: a basal one, one crossing the cell-apex, and an apical one being irregularly defined and with lighter, yellowish patches. Veins distinct and fine black. All the rest as in *balium*. Colombia (Rio Negro), Venezuela, Guiana. *zonata*.

H. hoffmannsi Rothsch. differs from the preceding by the orange abdomen being yellow-reddish beneath; the vertex and neck are more extensively orange. The forewings are more greyish-white, of a less

yellowish tinge with darker veins and a marking very much like *zonata*. Venezuela and North Colombia.

- pierus*. **H. pierus** Cr. (= *lucis* Btlr.) (24 g). This species and the two next ones, being often mixed up with each other, form a group of very similar animals. Head and thorax olive-grey, with blackish-brown spots and stripes, 2 spots in the neck and hips are carmine. The abdomen is brownish-black with traces of carmine segmental lines. Forewings greyish, towards the base with an olive-yellow tinge; at the base short, black stripes, the lowest of which is bent and extends as far as the middle of the proximal margin; a round spot in the cell, above it a small stripe at the costa; at the cell-end a transverse stripe and 3 irregular spots below it; behind the cell there is a row of spots, containing longer spots between the upper median and middle radial vein. An antemarginal macular band extends from the costa to the middle radial, and at the margin itself a row of small spots. Hindwings blackish-brown, in the disc diaphanous. Expanse of wings: 34 mm. Amazon (Rio Jutahi).
- picroides*. **H. pieroides** Rothsch. is somewhat larger and differs besides by a more yellow neck, the thorax being of a purer drab colour; the whole underside and a basal spot above on the 3 first abdominal rings are yellow-reddish; there are not any red segmental lines. The forewings are more whitish-grey with olive-grey veins. Amazon (Fonte Boa).
- stolli*. **H. stolli** Rothsch. is beneath of a deeper rosy colour; above the vertex and neck are more extensively carmine; thorax and abdomen are dark drab, the base of the collar and shoulder-covers more yellowish-grey. Hindwings dark sooty-grey without being discally lighter. The forewings are olive-yellow in the larger basal parts, sooty-grey in the apical parts with a lighter transverse line in the middle. The spots at the margin are obsolete. In the ♂ the basal part is of a greyer tint, not so yellow. Amazon (Fonte Boa; Teffé). —
- meridionalis*. subsp. **meridionalis** Rothsch. from San Antonio (Rio Madeira) has a black abdomen, grey thorax, and the forewings of a beautiful pearl-grey with bluish-grey veins and spots.
- sanguipalpia*. **H. sanguipalpia** Hmps. (24 g) is entirely unlike all the other species and looks, owing to the hyaline wings, something like a *Loxophlebia*. The body is black, the palpi, a spot between the antennae, spots on the thorax, and the underside of the anal tuft are carmine. The lower half of the forehead, the hips and the ventral side are white. Wings hyaline with fine black veins, margins and apical spots. Expanse of wings: 26 mm. Brazil (Blumenau).
- germana*. **H. germana** Rothsch. The description runs: „similar to *sericea*, but the abdomen above velvety black“, but it is not said which *sericea* it is. Described from Surinam.

145. Genus: **Eucereum** Hbn.

Beside *Cosmosoma*, this is the most diversified Syntomid genus containing species ranging from small sizes to the largest, the wings being mostly brown or grey with various markings, yellow or black spots, streaks, dentate lines etc. The abdomen is mostly red or yellow, but also brown. The genus already greatly approximates the Aretiids by the presence of a fragment of the costal on the hindwing— The rise of the uppermost subcostal vein on the forewing from the cell separates the genus from *Hyaleucerea*. The middle radial vein of the hindwing rises close at the lower and upper median veins or together with them.

- archias*. **E. archias** Stoll (24 g) is not to be mistaken by the long, yellow hair-tufts at the sides of the first abdominal ring, and by the lobularly widened, yellow proximal margin of the hindwing in the ♂. The hindwings are otherwise blackish-brown, the forewings greyish-brownish, with dark brown-spots. Forehips, spots on the neck, and abdomen carmine, the anal end black, the venter yellow. Guiana. — The larva is light yellow with long white hair-tufts on the anterior and posterior segments, and black dorsal spots on the same segments. It lives on Citrus and changes into a grey cocoon.
- albitorna*. **E. albitorna** Dogn. is much smaller than *minutum*, the anal angle of the hindwing being still more extended. It differs besides by its orange-yellow neck, sometimes also vertex, and brown abdomen on which only the anal tuft is ochreous-yellow. The hindwings are entirely black, with a broad whitish proximal angle and white fringes. Expanse of wings: 21 mm. East Colombia (Medina: 500 m).
- minutum*. **E. minutum** Druce (= *drucei* Kirby) (24 g) has a reddish-brown body, the 3 last abdominal rings are above orange-yellow. Forewings light brownish-grey with darker brown veins and spots; before the middle there is an indefinite undulate line; in the middle of the cell and at the end one small dark spot each; traces of an oblique, dark discal line; an antemarginal, irregular, dentate line and on the border short, small sagittal spots. Hindwings light yellowish-brown; the whitish proximal angle is pointedly produced, the proximal margin turned over and in this fold roughly sealed. Expanse of wings: 26 mm. Panama.

E. metalobum *Hmps.* differs from *minutum* (24 g) by the lobularly extended, but not turned over *metalobum*. and roughly haired proximal angle and anal angle of the ♂. The body is blackish-brown, mixed with grey; neck yellow. Palpal base, forehips and spots on the legs are whitish. Abdomen blackish-brown with yellow lateral spots on the last rings, beneath white. Forewings similarly marked as in *minutum*, greyish-white with brown veins, spots and dentate lines. Hindwings diaphanous grey, towards the margin tinted brownish-black. Expanse of wings: 30 mm. Peru.

E. phaeophlebium *Hmps.* The ♂ hindwing exhibits a cover of yellow hair in a fold on the under *phaeophlebium*. surface at the proximal margin. Head and thorax yellowish-brown, the abdomen more blackish-brown. Palpal base, hips and ventral side light rosy red. Forewings yellowish-brown with darker veins, the hindwings blackish-brown. Expanse of wings: 30 mm. Argentina.

E. integrum *Rothsch.* resembles the following species, but the border of the hindwing is convex, *integrum*. not concave. Head and thorax grey, with darker spots and stripes; palpi and legs are of a deep black. The abdomen is carmine, above at the base spotted yellow, with a black anal apex. Forewings yellowish drab, with black spots being similarly arranged as in *excavatum*. Hindwings dark grey, above the cell lighter diaphanous. Length of forewings: 19 mm. Amazon (Fonte Boa).

E. excavatum *Dogn.* and the following species are very characteristic by the peculiar shape of the *excavatum*. wings: both pair of wings are very broad, the hindwings between the greatly produced anterior and posterior angles concavely indented. The species before us has white forewings with black spots, the hindwings are whitish diaphanous in the basal halves, at the margins broadly black. The abdomen is carmine, at the base black, at the apex black and white.

E. flavum *Dogn.* (24 h) is apparently not a form of *excavatum*, but rather a good species distinguish- *flavum*. ed by its larger size, the abdomen being above and beneath yellow, and by the peculiarly blurred, dull not distinctly black spots of the forewings, French Guiana (St. Laurent du Maroni, Nouveau Chantier).

E. perexcavatum *Rothsch.* is somewhat larger than *excavatum*, with a unicolorously slate-grey abdomen, *perexcavatum*. a sooty-black, not rosy-red underside, a unicolorously grey thorax, olive-yellow, not whitish-grey ground-colour of the basal $\frac{4}{5}$ of the forewing, dark grey hindwings with a still more deeply concave border and a longer pointed proximal angle, Length of forewings: 19 mm. Amazon (Fonte Boa).

E. kennedyi *Rothsch.* Head and thorax sooty-grey, marked lighter, neck orange. The abdomen is *kennedyi*. black, the 3 last rings above carmine-rosy; the whole underside is light carmine rosy. Forewings orange-yellowish, with a rosy tint, in the basal two fifths with a number of grey spots; in the disc there is a broad, irregular band composed of similar spots, behind the cell a dark-grey spot from the costa to the middle radial, and an antemarginal series of spots. Hindwings dark grey, towards the base extensively diaphanous lighter. Length of forewings: 16 mm. South Brazil (Minas Geraes).

E. cinctum *Schaus.* Very much like the two following species, as large as *metoidesis*. Forewings *cinctum*. and thorax greyish-brown with black markings. Abdomen black, above from the 5th to 7th segments red, beneath yellow-reddish. Described from Trinidad.

E. rubroanale *Rothsch.* is very near to *cinctum* (24 g) and differs by the sooty black, not yellow- *rubroanale*. reddish or whitish colour of the ventral side, much darker thorax and blackish-brown forewings on which the light markings are confined to a small spot in the cell and a very fine, undulate, postmedian transverse line. The hindwings are darker and more uniform by the much less diaphanous basal half. The present species is besides much smaller. Length of forewings: 12 mm. Venezuela, Bolivia.

E. metoidesis *Hmps.* (= *cinctum* *Hmps.*, *latifascia* *Btlr.*) (24 h) is easily recognized by the costal *metoidesis*. margin of the hindwing being very concave at the base. Head and thorax brown, spotted black with two carmine spots in the neck. The black abdomen is carmine from the fifth to half of the 7th segment. The grey forewings, being more brownish at the margins, are spotted black, the semi-diaphanous whitish hindwings at the border black. Distributed from French Guiana as far as the Amazon.

E. obscurum *Möschl.* (= *stellifera* *Btlr.*) (24 g) is a small species with narrow wings, easily recog- *obscurum*. nizable by the bronze-lustrous black colour into which bluish-white scales, being partly in the shape of dentate transverse lines, are interspersed. The black abdomen has posteriorly a metallic blue lustre. Distributed from Mexico through Central America as far as the Amazon.

E. lemoulti *Schaus.* The body is black, on the collar and thorax with a leaden lustre, in the neck *lemoulti*. orange. Forewings bluish-grey, with black veins and base of the proximal margin. Hindwings black, in the disc diaphanous. Expanse of wings: 29 mm. French Guiana (Maroni River).

E. meruloides *Schaus.* Head, thorax and forewings dark leaden grey, the veins velvety black; a *meruloides*. black postmedian shade. The abdomen is black. Hindwings bluish-black, in the disc diaphanous. Expanse of wings: 39 mm. Peru.

- merula.* **E. merula** Dogn. (24 h). Head and thorax are bluish-grey, with blackish-brown spots and stripes. The abdomen is bluish-black, above at the base with brownish hair, the penultimate segment brown. Forewings bluish-grey with black veins, a faded black discal shade and spot at the cell-end; also an antemarginal, dark shade. Hindwings hyaline, the margin being irregularly clouded grey and black. Expanse of wings: 24 mm. Ecuador.
- fanum.* **E. fanum** Druce. Anterior body black, head and base of collar spotted white; abdomen bluish-black with a series of white lateral spots, chest yellow, the black legs underneath white. Forewings black with a large grey spot round the cell-end, the costal and proximal margin striped grey. Hindwings black, in the disc whitish diaphanous with black veins. Expanse of wings: 52 mm. Venezuela. It seems to be doubtful whether this peculiar animal, being known to me only from the description, belongs to the genus.
- maricum.* **E. maricum** Cr. (= *grylloides* Wkr., *thalassica* Fldr., *virescens* Möschl.) (24 i) has a blackish-brown body; in the neck two red dots; the thorax is marked orange-yellow. The forewings are bluish-white, veins and spots at the proximal margin and costa yellow, with numerous blackish-brown spots, which are more like streaks in the inner-marginal area and at the base; in the middle of the cell an isolated, small, round spot. The hindwings are bluish-white with a very broad, black border. Brazil, Bolivia. — subsp. **amazonicum** Rothsch. has the spots of the forewings more blurred, the postdiscal band being of a more yellow tinge, and the margin of the hindwing not so deep black and more irregularly defined. From the Amazon. —
- postcoeruleum.* **postcoeruleum** Rothsch. (24 i) differs from *amazonicum* by the very narrow black border of the hindwing, only an apical spot being more extensively black. Distributed from British Guiana through Venezuela as far as Bolivia.
- appunctatum.* **E. appunctatum** Dogn. (24 i) is similarly marked as *casca* and *albinotum*, but the abdomen is above carmine, the 2 first rings brown. Head and thorax likewise blackish-brown, in the neck a carmine ring. The blackish-brown forewings are veined light yellowish. Below the base of the cell is a small, white spot, in the cell-end a square, behind the cell a large, reniform, white spot between the 2nd subcostal vein and the middle radial. An antemarginal, indistinct, curved row of whitish dots. The hindwings are blackish-brown, towards the base whitish. Expanse of wings: 34 mm. Ecuador (Loja).
- rosa.* **E. rosa** Wkr. (24 h) has dark brown forewings with somewhat lighter yellowish veins with pale brownish markings, 2 antemedian small spots, a square one in the cell, an irregular, distal transverse line and an indistinct marginal dentate line. Hindwings blackish-grey. 2 spots on the vertex, and the neck are carmine. Thorax and first abdominal ring dark brown. Abdomen otherwise carmine, with a dark brown lateral line. Venter yellow. Mexico, Honduras, Paraná.
- rosadora.* **E. rosadora** Dyar (24 h) from Mexico is smaller, darker and much more indistinctly marked. —
- xanthodora.* In *xanthodora* Dyar the red colour turns yellow.
- rosina.* **E. rosina** Wkr. (= *rhodophila* Druce) (24 i). Head and thorax light grey, on the vertex a blackish spot, neck carmine, collar with a black spot, shoulder-covers margined with black. Abdomen light carmine, at the anus whitish, laterally more or less developed black spots. Forewings whitish, mixed with grey; the veins in the discal area yellowish. Blackish basal spots bordered with yellow, a series of 6 antemedian spots, the one above vein 1 longish, connected with the proximal margin by a yellow line running towards the base, median and submarginal, irregular rows of spots, as well as some marginal streak-shaped spots. Hindwings diaphanous white, at the border narrowly dark. Mexico, Venezuela, Trinidad, Brazil. — f. **imprimatum** Wkr. is distinguished by the yellow colour being greatly increased round the spots, so that the basal spots turn almost entirely yellow; the dark border of the hindwings is confined.
- hoegei.* **E. hoegei** Druce (24 i) has whitish forewings with quite pale, reddish-grey spots and transverse bands; on the transverse vein there is a somewhat larger spot, and below it a streak more towards the base, crossing vein 2. The anterior body is whitish, with faint brownish markings, the neck and abdomen pale carmine rosy, the latter with a white anal end. The red colour may be changed into yellow: **lutescens** form. nov. — From Mexico.
- arenosum.* **E. arenosum** Btlr. (24 i) has a pale grey-brownish head and thorax, the vertex and collar with small black spots. Abdomen light carmine, at the end blackish-brown, the anal tuft whitish; black lateral spots; venter yellowish white. Forewing whitish-grey, in the basal half mixed with a darker colour. Some dark basal and 5 antemedian spots are bordered light; a straight median and an irregular distal transverse row of darker spots touch each other in the disc by the large spots near the cell-end; a submarginal row of smaller spots is parallel to the border; at the base of the fringes there is another row of blackish marginal dots. Hindwings brownish-grey. — Mexico, Guatemala, Panama, Amazon, Espiritu Santo.
- trinita.* **E. trinita** Schaus. Head and thorax grey with small black spots. Abdomen above rosy with a black anus, beneath yellow-reddish with a black lateral stripe. Forehips rosy, legs otherwise grey. Forewings grey

with black small spots being arranged similarly as in *arenosum*. Fringes speckled black. Hindwings black, towards the base more grey. Expanse of wings: 25 mm. Trinidad.

E. rufidorsale *Rothsch.* is dark grey on the head and thorax, in the neck orange. The abdomen *rufidorsale* is unicolorously scarlet, with a grey anal apex. The underside is yellowish light rosy. The forewings are in the basal half of a pure white, at the base there is a black spot with a grey one below it, before the middle a transverse line, behind it one being broken up into grey spots. The distal half of the wing is white with yellow veins; across the cell-end runs a broad band, being composed of irregular, grey, confluent spots, extending from the costa to the proximal angle; before the apex we notice a dark grey band from the costa to the middle radial; the apex and a series of spots in front of the margin are likewise dark grey. Hindwings diaphanous drab. Length of forewings: 17 mm. Ecuador.

E. formosum *Dogn.* Head and thorax white with black dots, collar anteriorly somewhat bordered *formosum* with rosy. Abdomen rosy with one dorsal, 2 lateral and one ventral, black macular stripe, the last ring all black. Legs black, white and rosy. Forewings milky white with small black spots round which the white is somewhat brownish: 5 at the costal margin at equal distances, one in the middle of the cell, and one more towards the base, 2 each before and behind the transverse vein; behind them 4 more, then 6 before the margin and 3 more at the proximal margin. Fringes white. Hindwings somewhat smoke-coloured. Expanse of wings: 44 mm. South East Peru. — **dognini** *Rothsch.* from Mexico and Costa Rica has a dirty yellowish grey- *dognini* white ground-colour of the forewings and more brownish-grey hindwings.

E. ruficollis *Lathy* differs from *Hel. balia* (24 g) by its carmine neck and orange-yellow ventral *ruficollis* side. Venezuela.

E. leria *Druce* (24 k) has white forewings with very irregular, blackish-brown spots bordered with *leria* yellow, with grey dusting between them; hindwings light grey, at the border somewhat darker. Head and thorax white, spotted grey and black, neck red. Abdomen with black lateral spots and a blackish-brown anal apex. Ventral side yellowish, the segments margined with red. Palpi and legs spotted black and white, forehips inside red. — Mexico, Panama, Ecuador and Bolivia. — Occurs also with a yellow abdomen and neck: *lerioides* *Schaus.*

E. dilutius *Rothsch.* differs from *leria* (24 k) by its somewhat larger size, the spots on the forewings *dilutius* being much larger, though not so confluent and partly obsolete; besides the veins and margins of the spots are much more extensively orange-yellow. Length of forewings: 21 mm. Minas Geraes; Sa. Marta.

E. tarona *Hmps.* (24 k) is considerably larger than the preceding species, but otherwise it greatly *tarona* resembles them; it differs by the vertex being almost entirely black and the colours on the forewing being more clearly distributed; the black spots are more brightly bordered with orange. Mexico (Misantla), Panama, Brazil (São Paulo).

E. conspicuum *Rothsch.* is a very beautiful, large species from Costa Rica and Ecuador, being allied *conspicuum* to the following. The head and palpi are quite yellow, the thorax velvety black with a large yellow spot on the metathorax and a yellow proximal half of the collar. The abdomen is in the ♂ carmine like the whole underside, in the ♂ golden orange, the 1st and last segment and series of dorsal spots dark sooty grey. Forewings in the ♂ yellowish olive-grey, in the ♀ of a purer yellow. The veins, a spot near the base with an undulate line behind it, a spot at the costa and in the cell, a very large discal spot, an undulate postmedian line, a spot from the costa to the middle radial, a series of antemarginal spots, and a marginal line are velvety black. Hindwings whitish diaphanous, veins brown and margins grey. Length of forewings: 26 mm. Costa Rica; Ecuador.

E. giganteum *Druce.* Head black, neck carmine; collar and thorax black, with yellowish-brown *giganteum* stripes, and a large yellow spot on the metathorax. Abdomen black, above with carmine bands, the last rings all red. Forewings brownish-black with light yellowish veins; at the cell-end there is a brownish white spot, behind it a band of a similar colour; a light brownish antemarginal line extends from the apex to the proximal angle. Hindwings white, broadly bordered with black, with black veins. Expanse of wings: 58 mm. Colombia.

E. punctatum *Guér.* (= *mitigata* *Wkr.*, *cribrum* *Möschl.*, *zamorae* *Dogn.*, *reticulatum* *Btlr.*, *arcno-* *punctatum* *Druce*) (24 k). Head and thorax brownish-grey, spotted black, in the neck yellow and red. Abdomen red with a black terminal segment and lateral rows of black spots. Forewings whitish with grey veins and between them oblong, blackish-brown spots. Hindwings blackish-brown with a whitish diffuse patch below the cell. Distributed from Guatemala as far as Paraguay.

E. buchwaldi *Rothsch.* Closely allied to *punctatum* and discernible by the yellowish grey-white, not *buchwaldi* dark grey underside, by dark grey markings on the thorax, by a series of dark grey dorsal spots on the abdomen and by irregular, often sagittal spots and stripes on the forewing in the place of regular oval spots. West Ecuador (Quevedo).

E. hyalinum *Kaye* (24 k). Anterior body ochreous-brownish, marked black; neck yellowish-red, collar *hyalinum* black; on the metathorax a yellow spot. Abdomen black with subdorsal, almost contiguous, carmine spots

from the 5th to 7th rings. Forewing dark brown with lighter veins, at the distal margin from the lowest radial vein to the lower median vein of a lighter, isabel colour with rows of black spots arranged in the same way as in *punctatum*. Hindwings bluish transparent, at the border broadly black. Expanse of wings: 38 mm. Trinidad.

- leprotum*. **E. leprotum** Druce. Head, collar and anterior part of the thorax greyish, metathorax and the upper side of the abdomen as far as behind the middle blackish-brown; the abdominal sides and the last rings above brilliant red, apex black; underneath yellowish-white; laterally a series of small black spots. Forewings grey, the base, a round cellular spot, a spotted band at the cell-end, and a series of spots near the apex are greyish-black, as well as minute spots along the proximal and distal margins. Hindwings greyish-white, at the apex and distal margin greyish-brown. Expanse of wings: 42 mm. Venezuela.
- fosteri*. **E. fosteri** Rothsch. differs from *leprotum* by the entirely red abdomen, only the last segment being dark, by more densely spotted forewings and grey-white diaphanous hindwings. Length of forewings: ♂ 19 mm, ♀ 22 mm. Paraguay.
- dentatum*. **E. dentatum** Schaus (24 k). Anterior body grey, with blackish stripes, in the neck carmine. Abdomen above carmine, beneath white, laterally black like the last segment; the 1st ring is grey, often also 1 or 2 more rings exhibit small grey spots. Forewings light grey with numerous, darker, small spots and dentate lines. Hindwings grey, in the disc diaphanous. Expanse of wings: 31 mm. Mexico (Coatepec, Misantla).
- melanoperas*. **E. melanoperas** Hmps. (24 k) is distinguished by dark red-brown forewings with reddish-grey veins and narrow transverse lines; the one before the margin is strongly dentate. Two spots on the vertex, hips and abdomen pale carmine, the latter with brown lateral lines, and the first and last segment being brown.
- bolivianum*. Amazon. — subsp. **bolivianum** Rothsch. differs by lighter grey, almost white markings. Bolivia.
- rosenbergi*. **E. rosenbergi** Rothsch. is larger than *melanoperas*, with a large white spot behind the cell of the forewing and a quite sooty-black, not red underside of the abdomen. Length of forewings: ♂ 17 mm, ♀ 14 mm. Ecuador.
- pallada*. **E. pallada** Druce. Anterior body light fawn-coloured with black stripes; antennae and palpi black. Abdomen above brilliant red; the first and last segment, as well as lateral lines black; underside orange-yellow. Forewings light fawn-coloured, between the veins with blackish stripes. Hindwings diaphanous brownish, at the apex and distal margin darker. Expanse of wings: 46 mm. Paraná.
- flavopunctatum*. **E. flavopunctatum** Dogn. Anterior body black; forehead and vertex spotted black, collar and shoulder-covers bordered with yellow; shoulders and mesothorax spotted yellow. The abdomen is above brilliant red, the last ring and the underside black; hips yellow. Forewings white with yellow veins and rows of black spots, covering the wing to such an extent that there remain of the ground-colour spots only in the middle of the cell and below the median, as well as a band behind the cell from the subcosta to the upper median vein. Fringes black and white. Hindwings white with a black marginal band and veins. Expanse of wings: 33 mm. Colombia (Cali).
- dorsipunctum*. **E. dorsipunctum** Hmps. Head and thorax with small black spots and stripes; neck with 2 yellow spots. Forehips and abdomen above carmine, the latter with dorsal black spots, black lateral stripes and a black anal ring, underneath yellowish-white. Forewings white, veins, costal and proximal margins light brown with rows of black spots; in the middle of the cell there is a black spot with a light centre, but parted by a light longitudinal streak. Hindwings white with a marginal band of blackish-brown, being broad at the costa and narrow at the proximal angle. Expanse of wings: 34 mm. Venezuela; Paraguay.
- leopardinum*. **E. leopardinum** spec. nov. (24 l) greatly approximates *dorsipunctum*; it is smaller and differs above all by the absence of the black dorsal spots on the red abdomen; the palpi are at the base and at the terminal joint white; the hindhead is yellow and the neck exhibits 2 carmine spots. From the uniformly light yellowish-grey ground-colour of the forewings the margins and veins do not stand out darker. Peru (Hallapani), from BANG-HAAS.
- quadricolor*. **E. quadricolor** Wkr. (24 l). Head, thorax and forewings yellowish-grey-white with very prominent, black, small spots being bordered with orange, an especially long one above vein 1 at the base. Hindwings dark blackish-grey. Abdomen above carmine with a series of minute black dorsal spots, black anal apex and black lateral spots. Ventral side reddish-white. Brazil: Rio de Janeiro. — **centrale** form. nov. (= subsp. 1. Hmps.) (24 l), flying in Mexico, Costa Rica and Panama, is a form with considerably smaller spots of the forewings, the longish one on vein 1 being parted in two, the hindwings are of a paler grey, whereas the form from the northern parts of South America, Venezuela: **boreale** Rothsch. is smaller, but more brightly coloured, exhibiting larger black spots on a grey ground, and darker hindwings. — The southernmost form from Paraguay: **meridionale** Rothsch. is still smaller, the ♂ has quite grey forewings, the ♀ more purely white ones, the hindwings being yellowish brown-grey.
- atrigruttum*. **E. atrigruttum** Druce (24 l) greatly resembles the Mexican form of *quadricolor*, being about smaller by half, the black spots still smaller and paler, not margined at all with yellow; the hindwing in the disc white, at the border pale grey. The abdomen is of a dull rosy-red, beneath dirty white. It flies in Mexico and Venezuela.

E. marcatum *Schaus* is allied to the preceding. Head and thorax white with black spots. Abdomen *marcatum*. rosy with a brown first segment and a black apex; with short brown subdorsal stripes and a lateral row of black dots; underneath yellow-reddish. Forewings white with similar black spots as the preceding, and black margins; the most distal one of the costal-marginal spots is confluent with a large spot between the median veins, extending as far as the proximal angle. Fringes white, at the ends of the veins spotted black. Hindwings white with grey veins and border which grows broader at the apex and proximal angle. Expanse of wings: 33 mm. Paraguay.

E. clements *Schaus* differs from all the species by the forewings being marked carmine. *clements*. Anterior body and forewings are of a deep dark brown; rings on the palpi, the basal joint of the antennae, the neck, 2 spots on the metathorax, hips and rings on the legs are carmine. Abdomen carmine with a triangular, brown dorsal spot at the base as far as the 3rd ring; the last ring and lateral stripes are likewise brown. The forewings exhibit 3 red spots at the costal base, dentate and undulate red transverse lines before and behind the middle, ring-spots and reniform spots and oblong-oval rings before the margin. Hindwings blackish-brownish, in the disc diaphanous. Expanse of wings: ♂ 36 mm, ♀ 42 mm. Sa. Lucia (West Indies).

E. imriei *Druce* (241) is very easily recognizable by the black forewings being thinly strewn with *imriei*. yellowish-white scales, with 2 large, irregular, whitish costal spots before and behind the middle; the anterior one extends as far as the median, the posterior one to the upper median vein. Before and on the margin there are rows of more or less distinct dots. Hindwings blackish-brownish, towards the base diaphanous. The anterior body is black, on the thorax mixed with ochreous-yellowish. The neck, 2 spots on the metathorax, hips and abdomen are carmine, the latter above with a triangular basal spot, black apex and lateral macular stripes. Expanse of wings: ♂ 34 mm, ♀ 42 mm. Guadeloupe; Dominica.

E. chalcodon *Druce* (241, 261) differs from the allied, very similar species by the antennae being *chalcodon*. white above. Forewings with a round cellular macula being prominently bordered with whitish. The basal joint of the antennae, and the neck are carmine. On the carmine abdomen only the 2 first rings are above black, the 3rd ring shows a black spot. Rio de Janeiro; São Paulo.

E. pyrozonum *Hmps.* (25 f) differs from *chalcodon* by the abdomen being black above and beneath, *pyrozonum*. with orange subdorsal spots on the 5th ring and orange dorsal bands on the following rings. Hindhead and shoulders spotted orange or carmine; hips carmine or orange. On the blackish-brown forewings the veins and linear markings are olive-yellow, arranged about as in *chalcodon*. Particularly conspicuous is a whitish, four-cornered spot behind the round, black cellular spot and a yellow-white marginal spot with 2 black dashes in it. Expanse of wings: 40 to 45 mm. Venezuela; British Guiana as far as Bolivia.

E. sylvius *Stoll* (= *lutulentum* *Möschl.*) (25 a) is only half as large as *latifascium* which the species *sylvius*. resembles otherwise in the marking of the forewings and in the colouring of the abdomen, though the black dorsal spots are absent. The hindwings are much darker, almost one-coloured blackish-brown. Distributed from Mexico to Brazil (Amazon). The larva is densely covered with black and grey hair which grow much longer and thicker towards the posterior segments; the first segment exhibits some thick, yellow hair-tufts. It lives on orange-trees and makes itself a greyish-brown cocoon for the pupation.

E. antonia *Druce* is larger than the preceding species, head and palpi black, the neck yellow; on *antonia*. the brown abdomen only the 4 last rings above are red, the anus itself is black. The wings are more yellowish-brown with yellowish veins, the markings of a deeper black. Hindwings blackish-brown, the disc not being lighter. Expanse of wings: 40 mm. South East Peru.

E. pseudarchias *Hmps.* (= *archias* *Druce*) is a rather large species, distinguishable by the doubly *pseudarchias*. contoured pointed arch formed by the anterior transverse line between the submedian fold and proximal margin, and by the carmine abdomen with a black terminal segment and a large, triangular, jet-black dorsal spot at the base. — The species is very common and distributed from Mexico to the Amazon. — The red colour of the abdomen may be replaced by a burning orange: **aurantiaca** *form. nov.* (25 a) which is before *aurantiaca*. us from Guiana and the Amazon. — **completa** *form. nov.* is another form from the same habitats, in which *completa*. the apical spot at the base of the proximal margin is entirely filled up with black, forming a large black spot.

E. aeolum *Hmps.* (= *rhodophila* *Druce*) (25 a), from Mexico and Guatemala, has brownish-white *aeolum*. forewings with numerous, small, black-streak like spots: at the base on vein 1, two curved streaks form an oval being distally bordered by 2 spots of the anterior row converging into two rectangular spots; in the cell 2 spots being situate above each other; a middle row gets very irregular towards the cell-end. Some submarginal and marginal punctiform spots. Hindwings blackish-grey, somewhat transparent. Head and thorax grey, spotted black, in the neck two small orange spots. Abdomen at the base and at the end blackish-brown, otherwise carmine with black dorsal spots and lateral stripes, beneath yellowish.

E. hampsoni *Rothsch.* extremely approximates *aeolum* and differs by the underside being rosy-red, *hampsoni*. not yellow. The forewings are spotted more indistinctly, and the spots are partly inclined to converge. The hindwings are diaphanous sooty-black, not light grey. Length of forewings: 16 mm. Bolivia.

- tessellatum*. **E. tessellatum** Schaus likewise greatly resembles *aeolum*, but it is much larger. The colour of the anterior body and of the forewings is more lilac-grey, the spots in the neck of a salmon-rosy colour like the underside. The hindwings are somewhat darker. Expanse of wings: 38 mm. Costa Rica.
- cimonis*. **E. cimonis** Schaus. Head dark grey, sides of forehead and vertex, below the eyes and collar spotted yellow; palpi blackish-brown, at the base yellowish. Thorax olive-brown, striped black. The abdomen is above carmine, a large dorsal spot on the 3 first rings, subdorsal rows of spots on the others, broad lateral stripes, and the anal segment are black. The venter and hips of a salmon-rosy colour. Wings rosy grey, veins and cell-fold light olive-brown, black spots arranged similarly as in *latifascia*. Hindwings diaphanous blackish brown, veins and distal margin darker. Expanse of wings: 43 mm. Costa Rica; Venezuela; Ecuador.
- latifascia*. **E. latifascia** Wkr. (25 a) is a rather large species from Mexico, the whole of Central America, Pará as far as Pern. — The forewings are brown with black spots; the largest are situate: at the base of vein 1 and in the surroundings of the cell-end, particularly between the median veins. Postmedian distally long-dentate spots above the lower median vein, the middle and upper radial, with whitish diffuse spots between them; a submarginal row of oblong spots. Hindwings transparent blackish-grey, at the border darker. Abdomen red with a large, triangular, blackish-brown spot at the base and black apex. Single black dorsal spots; broad black lateral stripes. Venter yellowish-rosy.
- baleris*. **E. baleris** Dyar differs from the preceding by the much greater extent of the dark spots, so that they almost entirely cover the wing and there remain only fine light lines between them. Expanse of wings: 41 mm. Mexico (Santa Rosa, State of Vera Cruz).
- flemmingi*. **E. flemmingi** Rothsch. differs from *latifascia* by its unicolorously reddish buff underside, the hips not being red, the thorax of a unicolorous timber tint, the abdomen above more scarlet without any dorsal spots; the brownish-grey, triangular basal spot extends only across 3 rings; the last ring and sublateral stripes are of a timber tint, not black. The forewings are pale timber-tinted, the spots dark brown. Hindwings of a monotonous diaphanous brownish-grey with darker veins. Length of forewings: 22 mm. Ecuador.
- pilati*. **E. pilati** Wkr. (= *sylvius* Sepp, *conjunctum* Möschl.) (25 b) likewise greatly resembles *latifascia* and is smaller; the black spots are much smaller and thinner, more like streaks, the thick spots round the lower cell-end are absent. The base of the abdomen is less extensively black, the dorsal spots are completely present. From Mexico, Guatemala, Honduras, Colombia, Surinam.
- erythroleptis*. **E. erythroleptis** Dyar (25 b) is closely allied to *pilati*, somewhat smaller, with a paler ground-colour, more grey, all the black spots much smaller, in the shape of streaks, particularly the one between the median veins, being very prominent in *pilati*, is very small. The abdomen does not exhibit any black dorsal spots. Known only from Mexico.
- obliquifascia*. **E. obliquifascia** Rothsch. is lighter than *pilati* (25 b), with larger and more irregular spots on the forewings; the black stripe on the upper median vein is absent, but instead a broad, dark brown oblique band traverses the wing from the costal centre to the proximal angle. Trinidad.
- maja*. **E. maja** Druce (25 b) has light brown forewings, with darker reddish-brown little strokes and indistinct dentate lines and darker spots in the middle of the cell and at the cell-end, the latter with darker patches above and below them. Hindwings whitish, veins and margin darker. The abdomen is above carmine, beneath whitish with black dorsal and lateral spots. Distributed from Mexico through the whole of Central America as far as Guiana; also in Trinidad.
- myrtusa*. **E. myrtusa** Druce (25 a) is a large species from Mexico and Costa Rica with greyish-brown, black-marbled forewings; at the base of the proximal margin and below the cell-end there are large black spots. Hindwings diaphanous light grey, at the border somewhat darker. Head and thorax of the same colour as the forewings. The first and last abdominal segment blackish-brown, abdomen otherwise above carmine with black dorsal spots, and with lateral spots being coherent beneath. Venter yellow.
- patrona*. **E. patrona** Schaus (25 b) resembles *myrtusa*, but it is easily recognizable by the broad, blackish-brown longitudinal band traversing the whole forewing from the base to the apex, being only shortly before twice interrupted. From Mexico (Orizaba, Misantla: May, June, October) and Venezuela.
- patulum*. **E. patulum** Dogn. (= *patronides* Rothsch.) differs from *patrona* by the carmine-rosy, not yellowish underside and hips, and by the deeper black markings on the forewing, being concentrated to larger spots particularly above the longitudinal stripe in the middle of the cell and at the cell-end, the shape of the wings being somewhat broader and the border of the hindwing more convex. Expanse of wings: 45 to 48 mm. Peru.
- servator*. **E. servator** Kaye differs from *patrona* (25 b) by the hindwings being of a quite unicolorous, diaphanous pearl-grey colour. The dark brown abdomen exhibits only the two penultimate rings vermilion, the 4 preceding ones being coloured red only at the sides. Expanse of wings: 44 mm. Venezuela (Caracas).

E. casca Dogn. (25 c). The large, white, subapical oblique spot of the brownish-black forewing makes *casca*. the species easily recognizable; the veins are striped orange-yellow, of which colour are also 3 small costal spots, the third at the beginning of the subapical spot; a small spot in the middle of the cell is whitish. Hindwings diaphanous with blackish margins. Body blackish-brown, anterior body with orange stripes and spots, the three first ventral segments with white bands, the two last rings above spotted orange. Ecuador, Bolivia.

E. pseudocasca Rothsch. is discernible from *casca* (25 c) by the pale sea-green, not orange-yellowish *pseudo-casca*. veins and spots; the dark ground-colour recedes greatly; the basal area of the hindwing is of a much purer and more extensive white, and the ventral side exhibits a white, not yellow spot. Length of forewings: 19 mm. Peru (Carabaya), taken in January.

E. albinotum Dogn. is smaller than *casca* (25 c) and differs by the absence of the white spot on the *albinotum*. metathorax, the abdomen being entirely brownish-black, only the anus and a small dorsal spot on the 1st ring being yellow, beneath the rings are margined with yellow. The postmedian white spot on the forewing is shorter, extending only to the middle radial, and is dentate on the 1st radial vein; beside the small orange spot above it there are at the costa 2 more, one in the middle. Expanse of wings: 34 mm. Colombia (San Antonio).

E. darantasia Druce (26 l) is larger than *casca* (25 c), otherwise on the whole rather like it, but the white *darantasia*. spot behind the cell is absent; instead of it we notice a very pointedly dentate, yellowish transverse line. In the middle of the cell and at the end of it there are black spots, between them a small whitish spot. The orange spots in the neck and the whitish spots on the metathorax are absent. Expanse of wings: 46 mm. Costa Rica.

E. flavicaput Hmps. (= *leucophaea* Druce) (25 b). This species and the following ones are very much *flavicaput*. alike; the forewings exhibit, on the yellowish ground-colour, dark veins and 3 dentate lines crossing each other. **E. flavicaput** is one of the darker species, of a yellow-brownish ground-colour, suffused with olive-brown particularly at the proximal margin, base and cell-end. The brownish-grey head exhibits on the vertex two orange spots, the two last abdominal segments are orange. Mexico, Guatemala, Costa Rica, Ecuador.

E. bricenoi Rothsch. Like *flavicaput* (25 b), but with a much lighter yellow ground-colour. The *bricenoi*. median area of the forewing and a postdiscal band from the subcosta to the upper median vein are entirely white. Venezuela (Merida); Colombia (Choachi).

E. griseatum Rothsch. differs from the preceding by the olive-brownish grey-ground-colour. The hind- *griseatum*. wings of the ♂ are white in the basal $\frac{3}{4}$, in the ♀ entirely dark grey. Peru.

E. leucophaeum Wkr. (25 c) from Brazil (Rio de Janeiro) and Paraguay is the most similar to the *leuco-phaeum*. following species, distinguished by the metallic blue spot on the forehead, and the metathorax exhibits a blue spot, too, both, however, being absent in the ♀. On the abdomen the two last rings are above orange, in the ♀ only one ring. The hindhead shows two whitish spots.

E. xanthurum Schaus (25 c) differs from *leucophaeum* particularly by the two dark orange spots on *xanthurum*. the hindhead. Forehead and metathorax in the ♂ do not exhibit any blue spots. In both sexes only the last abdominal segment is orange. Mexico, Costa Rica, Brazil.

E. apicaflava Kaye differs from *xanthurum* chiefly by the absence of the antemedian dentate lines of *apicaflava*. the forewings which are clouded grey with darker scaled veins. At the costa above the middle of the cell there is a dark spot and in the surroundings of the transverse vein a large spot extending to the costa; the subapical dentate band is followed by a narrow, greyish-white macular band. At the proximal angle there is an irregular spot. Venezuela (Caracas).

E. decorum Schaus. Body blackish-brown, thorax and shoulder-covers striped white; the 1st palpal *decorum*. joint, the hindhead, a small spot at the articulation of the forewing, and the 2 last abdominal rings are orange. Venter spotted white. Forewing as far as the posterior transverse line light brown, then whitish; the veins, a stripe from the base of the median to the upper cell-angle and one below the submedian are black; before the middle a dark transverse line being angular in the cell; the posterior transverse line makes two bends from the costa to the upper median vein, then turning to the middle of the proximal margin; an antemarginal, irregular, blackish-brown shade; the uppermost radial vein and the 2 subcostal veins above it are of a more intense black. Hindwings blackish-brown, in the disc whitish. Expanse of wings: ♂ 42 mm, ♀ 49 mm. Costa Rica.

E. surcatum Dogn. Head and thorax brownish-grey; neck yellow; abdomen above black, the 2 last *surcatum*. rings yellow; the underside yellowish. Forewing yellowish-brown, traversed by irregular, rusty-red zigzag-lines: 3 near the base, and 5 in the distal half, between there is a large discal spot. Hindwings blackish. Expanse of wings: 42 mm. Ecuador (Loja).

E. lutetia Druce (25 d) exhibits on the brown forewings behind the cell an indistinct white spot. *lutetia*. The brown body has an orange-yellow abdominal end. Panama.

- marmoratum*. **E. marmoratum** *Btlr.* (= *flavofasciatum* *Möschl.*) (25 c) on the forewings is on the whole similarly marked as the following, but of a darker colouring, dark brownish-grey. From Guiana to the Amazon. — *atratum*. f. **atratum** *Rothsch.* is still much darker, sooty brownish-black. — Venezuela.
- simile*. **E. simile** *nom. nov.* (= *tessellatum* *Rothsch. nec Schaus*) differs from *marmoratum* by the smaller size and narrower forewings, the shoulder-covers being light yellowish-grey bordered with brownish-black, not dark grey with black stripes; the whole thorax is yellowish-grey, not dark grey, of the same colour are the forewings; the veins are dark brown, the antemedian dentate line is only visible at the proximal margin; an irregular, dark brown oblique band extends from the costa to the proximal angle, at the apex there are 2 brown bands. Length of forewings: 18 mm. Venezuela; Surinam; Colombia.
- complicatum*. **E. complicatum** *Btlr.* (25 c) resembles *flavicaput* on the forewings, the marking is somewhat finer, but the abdomen is quite different: orange-yellow, with a triangular, blackish-brown basal spot and black terminal segment, on the ventral side whitish-yellow. From Brazil (Amazon); before me also from East Colombia (Rio Negro) and Bolivia.
- albidius*. **E. albidius** *Rothsch.* is much larger than the preceding. Head whitish grey with orange spots. Thorax whitish with narrow sooty black margins. The abdomen is blackish-grey and exhibits only on the 2 last rings above a large orange spot. Forewings creamy white with 3 irregular, transverse zigzag lines, veins and a discal spot of a sooty-brown colour. Hindwings sooty-grey with darker veins. The ♀ has more grey forewings and a lighter disc of the hindwing. Length of forewings: 27 mm. Amazon (Fonte Boa; Manaos; Rio de Janeiro).
- compositum*. **E. compositum** *spec. nov.* (25 d) combines the characters of *complicatum* and *pyrozonum*, the markings in the basal part of the forewing being like in the former, in the marginal area like in the latter. Body light greyish-brown, with darker markings, abdomen like in *complicatum*. 1 ♂, the patria not being stated, in the Coll. SEITZ.
- amadis*. **E. amadis** *Schaus* (25 d), from Mexico (Coatepec, Misantla) and Colombia, is on the forewings coloured and marked almost exactly like *latifascium* *Wkr.*, only somewhat darker, the head and thorax unicolorously deep blackish-brown, the hindhead exhibiting two orange-yellow spots. The abdomen except a large, triangular, blackish-brown spot at the base and the black apex, is ochreous-yellow, which colour is separated from the ventral surface being somewhat lighter by a blackish-brown lateral stripe.
- tripunctatum*. **E. tripunctatum** *Druce* (25 d) looks very much like *myrtusa* *Druce*, except being somewhat smaller, but owing to the ground-colour being somewhat lighter, reddish-brown, the 3 black spots at the base, below the cell-end and before the apex are more prominent. The abdomen is ochreous-yellow with a large, triangular, black spot at the base, rows of black dots across the dorsum and at the sides and black anal apex. Mexico, Guatemala, Costa Rica, Panama.
- velutinum*. **E. velutinum** *Schaus* (25 e) has light brown, darker dotted forewings with single, darker, small spots; from the middle radial vein to the proximal angle extends an indistinct line growing much broader here; the hindwings are blackish-brown. The abdomen is at the base blackish-brown, otherwise orange with black dorsal and lateral spots, the venter whitish. Brazil (São Paulo).
- striatum*. **E. striatum** *Druce* (25 e) is a species well characterized by the peculiar shape of the wings: the long-extended forewing is strongly bent at the costal margin towards the apex, below the lower radial begins a concave indentation of the distal margin. Yellowish white, tinted olive, with blackish-brown veins and longitudinal markings. More prominently white longitudinal streaks are below the lower median and above the middle radial vein. Hindwings light grey transparent. Abdomen blackish-brown with ochreous-yellow spots growing larger towards the anus on the sides of the 5 last segments. Mexico, Costa Rica, Panama, Ecuador, Brazil. — subsp. **pallescens** *Rothsch.* from Paraná, is of a much paler colour, the markings less distinct and partly vanished.
- perstriatum*. **E. perstriatum** *Hmps.* is extremely near to the preceding and differs chiefly by its entirely dark brown abdomen with subdorsal and sublateral yellow spots only on the 2 last rings; the 3 first rings exhibit beneath hairy, white spots. On the forewings the transverse lines are more distinctly prominent. Expanse of wings: 44 mm. South East Peru.
- reniferum*. **E. reniferum** *Hmps.* (25 f). The anterior body is grey, spotted and striped black, the neck yellow; the orange-yellow abdomen shows a large, triangular, blackish-brown basal spot, black lateral stripes and anal apex; venter white. The forewings are light grey with black veins and strongly bent transverse lines; at the transverse vein there is a large, brown spot with a lighter pupil, expanding still more below the cell. Hindwings blackish-brown. Amazon. Pebas.
- coenobita*. **E. coenobita** *Möschl.* (25 d) approximates the following species, but it is darker on the whole; head and thorax are quite blackish-brown, only the upper part of the forehead and a transverse band behind the collar are white. The abdomen is browner, the 2 last rings above quite orange. The black spots on

the forewings are much more irregular, on the whole larger and form behind the middle a complete, broad, postdiscal band. Expanse of wings: 46 mm. Jamaica.

E. picoides *Rothsch.* differs from *coenobita* (25 d) by its creamy ground-colour, the spots on the forewings being not so black, more brown, being at the same time larger and inclined to flow together. — From Santa Marta, in September and October. *picoides.*

E. pica *Wkr.* (25 e) is a large, easily recognizable species with yellowish-white forewings being irregularly spotted black; head and thorax are white, marked black; behind the eyes and on the metathorax there are very small orange spots. The abdomen is blackish-brown with broad, orange-yellow, lateral macular stripes which are more or less confluent above on the posterior rings. Ventral side for the greatest part white. From Rio de Janeiro and São Paulo. — subsp. **tigrata** *H.-Schüff.* (*peruviana* *Schaus*) is of a purer white with reduced black markings on the forewings. The hindwings are blackish-brown, lighter in the disc. *pica.* *tigrata.*
Costa Rica; Panama; Venezuela; Peru.

E. consortium *Schaus* is on the forewings marked very much like *pica* (25 e), somewhat smaller and distinguished by the abdomen being above orange; only the last ring and a spot on the penultimate ring are black; underneath white, the two last rings and sublateral rows of spots black. Head white, the palpi black, at the ends of the joints spotted white. Collar black with 2 large, creamy-white spots; the thorax is all white, only on the shoulder-covers and the metathorax there is one black spot each. Expanse of wings: 40 mm. Costa Rica. *consortium.*

E. exile *Strand* (26 l) is closely allied to *coenobita* and *consortium*; from the latter it differs by a uniformly black terminal joint of the palpi, the 1st joint exhibiting a white spot at the tip. Head creamy-yellowish with a black forehead. The abdomen is black, with orange lateral stripes which begin narrow, growing broader posteriorly and being united on the two last rings. Expanse of wings: 44 mm. Described and figured according to a ♀ from Ecuador (Coll. NIEPELT). *exile.*

E. tigrisoma *Rothsch.* approximates the preceding. Head and thorax white, bordered with black. The abdomen above black, the 1st ring and a broad dorsal band slate-grey; the rings 3 to 7 exhibit lateral large orange spots. Forewings white with black spots; the disc is crossed by a similar, black oblique band like in the allies. The hindwings are diaphanous white in the basal two thirds, the distal third being brownish-grey. Length of forewings: 21 mm. Brazil (Preto). *tigrisoma.*

E. davidi *Dogn.* (25 e) has a certain exterior resemblance to *pica* and its allies; head and thorax are white, spotted black. The abdomen is black with orange lateral spots on the rings 3 to 7. The forewings are preponderantly black with irregular white spots, the hindwings hyaline with a black marginal band and black veins. Expanse of wings: 44 mm. Ecuador; Bolivia. — In **clarius** (= subsp. 1 *Hmps.*) *clarius.* *nom. nov.* the white colour appears more extensive on the forewings; the abdomen has orange lateral spots only from the 3rd to 5th rings. Peru. *davidi.*

E. ockendeni *Druce.* Body black; sides of the head and collar white. Abdominal sides spotted yellow; the first rings beneath white. The markings of the white forewing similar as in *davidi*, but much finer and divided into smaller spots. Hindwings transparent white, apex and distal margin black. Expanse of wings: 52 mm. South East Peru. *ockendeni.*

E. varium *Wkr.* (25 e) is a large species with brown forewings and yellowish-grey veins and linear markings. The species is recognizable by a yellowish-grey marginal spot between the lower median and lower radial vein with 2 small black spots in it, furthermore a square light spot in the cell-end and the hyaline hindwings with a broad, sharply defined black border. The black abdomen is orange-red on the segments 5 to 7; on the 4th ring there are mostly subdorsal, orange spots. From Panama as far as the Amazon. *varium.*

E. steinbachi *Rothsch.* The head is dark grey, in the neck golden-yellow; the thorax olive-yellow, bordered with dark grey; abdomen yellowish carmine, the first 3 rings and the anal tuft with greyish-black hair. Forewings olive-yellow, in the marginal area between the 2nd median and 3rd radial cream-coloured, covered with sooty grey longitudinal spots and lines forming at the cell-end a more or less distinct, roundish spot. Hindwings sooty grey. Length of forewings: 20 mm. East Bolivia. *steinbachi.*

E. setosum *Sepp* (25 f) is widely spread from Mexico to Bahia; it has long-extended, grey-brownish forewings with darker veins bordered with olive-yellow, and with transverse rows of longish, dark-brown, yellow-ringed spots; the hindwings are diaphanous light grey, at the border darker. Abdomen like in the allies ochreous-yellow with a large, dark brown, triangular basal spot, the apex of which extends as a dorsal stripe as far as the black anal apex. Distributed from Mexico to Brazil. — **relegatum** *Schaus* from Costa Rica is probably only a somewhat smaller, darker form of it. On the body deeper black, the thorax marked brown. Spots of the forewings black, bordered with yellow-reddish. *setosum.* *relegatum.*

E. mara *Kaye* approximates *setosum*, but it is of a purer white and opalescent, with light yellowish veins. At the costa there are 3 light yellow spots at equal distances. Hindwings transparent opalescent, the veins towards the margin brownish. Expanse of wings: 40 mm. Venezuela. *mara.*

- cubense*. **E. cubense** Schaus. Head and thorax olive-grey with black, small spots and stripes bordered with olive-yellowish. Abdomen above black, laterally and on the three last rings also above yellow with 2 black dorsal spots and a black transverse band on the last ring; beneath white; laterally spotted black. Forewings whitish-grey, veins, costa and proximal margin olive-green with oblong, black spots in the cell and between the veins, arranged similarly as in the preceding. Hindwings white, veins and margin blackish. Expanse of wings: 38 mm. Cuba.
- rogersi*. **E. rogersi** Druce (25 f) is the nearest to *setosum*, differing by the broader shape of the wings, somewhat lighter total colouring, the colours being more clearly distributed, not so much dusted over with grey, all the spots somewhat rounder, not so long extended. The hindwings are darker. From Mexico, Costa Rica, Panama.
- confine*. **E. confine** Herr.-Schäff. (25 f), among the allied species, has the purest white ground-colour, the veins are olive-grey, scarcely bordered with yellowish. Head whitish-grey with a large black spot on the vertex and an orange-yellow neck-ring. Collar grey with large, black spots, shoulder-covers whitish-grey, bordered with black. Widely distributed from Florida and Mexico as far as Brazil. — v. **carolina** Hy.-Edw. (= *confine* Holl.) is the northern form from Florida.
- confusum*. **E. confusum** Rothsch. (25 g) extremely resembles *confine*: the ground-colour is not such a pure white, but more of an olive-grey tint, the veins are more yellowish; the spots on the forewing are not black, but more sooty brownish; the yellow of the abdomen is lighter and duller, not so brilliant orange-yellow, the hindwings are dirty grey. Widely distributed from Mexico, Costa Rica, Panama as far as Venezuela. — subsp.
- amazonum*. **amazonum** Rothsch. from Surinam and the Amazon is of a browner tinge, the markings are more hazy, the hindwings of a pure white, semi-transparent.
- myrina*. **E. myrina** Druce (25 g) is on the forewings similarly marked as *confine*, but much duller and finer on the semi-diaphanous white ground. The whole insect is generally smaller, of a more graceful structure, and the abdomen is all yellow with black dorsal and lateral spots. From Mexico as far as Guatemala.
- moeschleri*. **E. moeschleri** Rothsch. Head and thorax light yellowish brown, with darker grey-brown stripes; abdomen above lemon-coloured, the 2 first segments and the last one, as well as a dorsal band of a yellow-brownish grey; the whole underside is brownish-white. Forewings light brownish olive-yellow with some whitish hyaline markings, and spotted and striped brown. Hindwings diaphanous whitish, bordered with drab. Length of forewings: 19 mm. Jamaica.
- parambae*. **E. parambae** Rothsch. (25 g). Head and thorax drab, with darker spots, in the neck yellow. Abdomen above orange with a grey anal apex, the whole underside is of a dirty yellowish. Forewings grey-whitish with grey veins, with 2 antemedian transverse rows of dark grey spots, in the middle a double band of large spots, being divided into 3 bands below the median, one of which runs to the proximal angle; behind them and before the margin, from the costa to the upper median vein there are yet 2 rows of spots. Hindwings dark grey. Length of forewings: 19 mm. Ecuador.
- guacolda*. **E. guacolda** Poey is on the anterior body pale ochreous-brownish, spotted blackish. The abdomen is orange-yellowish, with dorsal and lateral blackish spots, on the venter whitish. On the yellowish-grey forewings, at the base of the median, there is a short black and carmine stripe; at the base, in the cell and at the cell-end some blackish dots; a postmedian row of small spots extending from the costa very obliquely in a proximal direction; the spot below the lower cell-angle is longer than the others; before the margin and on it there are yet rows of minute spots. Hindwings black-brownish, cell and inner-marginal area yellowish. Expanse of wings: 40 mm. Cuba.
- ochrotum*. **E. ochrotum** Hmps. (= *guacolda* Hmps.) is darker than the preceding, more ochreous-brown, all the spots black; the abdomen is orange. Jamaica.
- popayanum*. **E. popayanum** Dogn. Head and thorax orange-yellowish, vertex yellow. Abdomen above yellow, the 1st ring grey, on the following ones as far as the penultimate brown dorsal bands, the sides and venter are whitish. All the wings of a light yellowish-grey. Expanse of wings: 32 mm. Colombia (Popayan).
- abdominale*. **E. abdominale** Wkr. Brownish-grey, neck and abdomen orange, the three first segments above spotted grey. The forewings exhibit 4 darker brown undulate lines, a round spot in the middle of the cell and one at the cell-end; at the border short streak-spots between the veins. Hindwings darker brown. Venezuela.
- aoris*. **E. aoris** Möschl. (25 g). Head and thorax are whitish, the collar yellowish, the chest black-brownish. The abdomen is light yellow, the last ring black; narrow lateral stripes are black, the ventral side white. The forewings are grey with black spots, arranged similarly as in *atrigruttum*, but more extensive. Hindwings semi-diaphanous whitish with a brownish marginal band growing much narrower towards the proximal angle. Expanse of wings: 30 to 40 mm. Surinam.
- inconspicuum*. **E. inconspicuum** Lathy differs from *aoris* (25 g) by the abdomen being also underneath orange-yellow, the two last rings above and the 4 last rings beneath being black. The neck and forehips orange, collar

black-brownish. Forewings very much like in *aoris*, hindwings brownish-black with a diaphanous disc. British Guiana (Demerara).

E. ecuadoris *nom. nov.* (= *buchwaldi* *Rothsch.*) is much smaller than *aoris*. Head and thorax dark grey, collar lighter grey; neck, abdomen and the whole underside monotonously yellow. Forewings light grey with transverse rows of dark grey spots; 4 of them, next to the base above and below the inner-marginal vein, bordered with yellow. Hindwings diaphanous whitish-grey with a broad drab margin and apex. Length of forewings: 14 mm. West Ecuador.

E. ladas *Schaus.* Head and thorax are brownish-black mixed with greyish-white. Abdomen brownish with orange-yellow transverse bands on the 3 last rings, which are more prominent in the ♀. Forewings grey-white with blackish-brown veins; in the middle of the cell and at the end minute darker spots. Before the middle there are traces of a dentate line, behind the middle an irregular line, the latter surrounds the cell in an arch-like way and then turns towards the middle of the proximal margin. Before the margin dark, small sagittal spots. Hindwings blackish-brown, in the ♀ towards the base lighter. Expanse of wings: 24 mm. Rio de Janeiro.

E. xanthoperas *Hmps.* (= *abdominale* *Druce*) (25 i) has brownish-grey forewings with a small dark spot in the middle of the cell, a larger one at the end of the cell and minute, antemarginal sagittal spots. Hindwings brownish-white diaphanous; body brownish-grey, the 3 last abdominal rings orange-yellow. Mexico; Guatemala; Costa Rica.

E. flavicineta *Schaus* (25 h) is easily recognizable by the penultimate yellow abdominal ring, whereas the others are unicolorously blackish-brown. Characteristic is, furthermore, the marking in the cell of the forewing exhibiting in the middle a black circle and on each side of it a black streak along the cell-fold; moreover, on the whitish-grey forewings, the veins and dentate lines are blackish; the transverse vein appears as a light grey angular streak out of the blackish surroundings. The hindwings are light grey, bordered with blackish. Peru and Bolivia (Rio Longo).

E. sadana *Druce.* The head is black with a red vertex; the rest of the body dark brown, beneath rosy-red; legs brown. Forewings unicolorously dark brown, hindwings diaphanous brownish-black. Expanse of wings: 33 mm. Peru (Carabaya).

E. mathani *Schaus.* Head and thorax brown, in the neck 2 yellow spots. Abdomen above blackish-brown, beneath yellow, with brown bands; anal hair yellow. Forewings brownish-grey with dark brown markings: a basal spot, an antemedian, undulate, bent band, in the cell a square spot followed by a lighter brown transverse spot, at the cell-end and behind it a large spot, divided by the veins into 6; a postmedian row of longish spots and an antemarginal, similar, though smaller one. Hindwings brownish-grey, towards the base diaphanous. Expanse of wings: 33 mm. Ecuador.

E. rabusculum *Dogn.* Body dirty white, mixed with grey, abdomen curled grey, the last rings covered with long, grey hair. Forewings whitish-grey, traversed by 6 broad grey transverse bands: a basal one spotted black, one behind it, an antemedian band, close behind it a fourth growing much broader on the transverse vein and forming a large black costal spot, and 2 at the margin, which are scarcely separated, the distal one darkened on both the upper radial veins. Fringes grey. Hindwings white with a minute discal spot and a grey costal margin and border, at the apex broader. Expanse of wings: 45 to 48 mm. South East Peru.

E. costulatum *H.-Schäff.* (25 h). The forewings are marked as in *phaeoproctum*, but the yellow is darker and the apex of the abdomen is orange as in *aroa*. Panama, Venezuela.

E. costinotatum *Dogn.* Anterior body blackish, marked whitish-yellow; abdomen black, the last ring yellow, beneath black; the rest of the ventral side dirty white. Forewings yellow-white, the veins and the middle costal third black; before the apex is a large white spot extending down as far as the middle radial. Forewings black, towards the costa whitish. Expanse of wings: 30 mm. Brazil (Paranapanema). *SCHAUS* places this species to the genus *Hyaleucera* and beside *sororia*.

E. aroa *Schaus* (= *costulatum* *Druce*) (25 h) has whitish forewings, costal margin, discocellular and proximal margin striped yellow. The veins, a stripe in the discocellular and the submedian fold greyish-brown, as far as behind the cell-end, in some places thickened to a spot, then follows a reniform, light spot; the apex is again smoky grey. Thorax and abdomen grey-brown, in the ♂ the last ring, in the ♀ the two last rings orange. The venter is more or less whitish. On the hindhead 2 orange-yellow spots, the shoulder-covers striped orange. Distributed from Mexico to Brazil.

E. tenellulum *Schaus* (25 h). Palpi, head, collar and thorax brownish-grey; stripes on the shoulder-covers and 2 spots in the neck orange. Abdomen, except the orange-yellow last ring, brown-grey, on the ventral side more or less whitish, in the basal half and on the veins round the cell-end light ochreous-yellow. Blackish-brown, oblong spots arranged similarly as in *aroa* leave a reniform, almost purely white spot free before the apex of the wing, this spot projecting between the middle radial and the lowest subcostal vein

strongly convex towards the base. A subterminal macular band with the longest spot between the median veins and the largest between the middle radial and lowest subcostal vein; a terminal row of spots from the apex to the upper median vein, below it the margin is white. From Mexico (Orizaba: March and August) and Costa Rica (Juan-Vinas).

scyton. **E. scyton** Cr. (25 i) differs from *aroa* by grey forewings with a brown tint and without any yellow, with black veins and other markings: an antemedian, doubly angled transverse line; a postmedian, oblique line from the costa to the upper median vein, where it makes an angle and runs to the middle of the proximal margin; behind it there is a light spot with a dentate, distal border. The marginal area is dark with irregular, often contiguous, grey spots. Hindwings diaphanous blackish-brownish, towards the margin darker; body as in *aroa*. Expanse of wings: 32 mm. Distributed from Mexico through British Honduras, Surinam as far as São Paulo.

schausi. **E. schausi** Rothsch. is much larger and of a purer white than *scyton*. Head and thorax greyish-white, margined by a darker sooty grey, in the neck spotted orange. The abdomen is sooty grey, the last ring yellow, proximally margined by black. The underside is broadly banded white. Forewings white with blackish-brown veins, irregular spots and stripes. Hindwings diaphanous grey with darker margins. Length of forewings: 19 to 23 mm. Mexico; Costa Rica; Colombia; Ecuador.

lithosioides. **E. lithosioides** Rothsch. Head and thorax light yellowish brown, abdomen darker sooty brown, with a yellowish anal apex. The forewings are in the basal $\frac{4}{5}$ yellowish wooden brown, in the distal fifth more yellow reddish; antemedian and postmedian, curved, darker brown transverse bands. At the transverse vein, on the median, at the base of the lower median vein, and in the disc and at the proximal angle on the inner-marginal vein there are black dots. Hindwings brownish grey, in the disc diaphanous. In the ♀ the forewings are darker ribbed, the transverse bands are more distinct and at the transverse vein there are 2 dots. Length of forewings: 17 to 19 mm. Rio de Janeiro; Venezuela.

fuscatum. **E. fuscatum** Rothsch. Head and thorax dark brown, in the neck spotted orange. The abdomen is above black with an orange-yellow anal apex, beneath yellow, banded black. Forewings light clayish-brown or more greyish brown with irregular, dark brown transverse bands at the base, in, behind the middle, and before the margin. Hindwing in the basal half diaphanous drab, distally darker grey. Length of forewings: 17 mm. Ecuador.

fuscobrunneum. **E. fuscobrunneum** Rothsch. is uniformly dark olive-brown with a black abdomen and a yellow anal end. The forewings exhibit 2 darker transverse lines and a whitish postmedian shade from the costa to the proximal angle. Hindwings diaphanous sooty-blackish. The ♀ is larger, the hindwings darker. Length of forewings: ♂ 15 mm, ♀ 17,5 mm. Ecuador (Paramba).

fuscoirroratum. **E. fuscoirroratum** Rothsch. is a small, monotonously dark chocolate-brown insect. The forewings are watered with numerous, irregular, yellowish-grey transverse lines and bands. Length of forewings: 14 mm. Venezuela. — subsp. **minor** Rothsch. from the Rio Madeira (San Antonio) is still smaller and exhibits orange spots on each side of the abdominal rings 3 to 6.

strix. **E. strix** Rothsch. The body is dark brown, beneath mixed with whitish. Forewings wooden brown, striated darker brown; at $\frac{2}{5}$ of the length of the costal margin there begins a broad black line forming an arch and running on the inner-marginal vein into the base; at the transverse vein there is a dark line, behind it a bent transverse line followed by an oblique whitish line terminating on the lower median vein into the margin. The apex and a bent antemarginal line whitish. Hindwings diaphanous sooty grey, veins and margin darker. Length of forewings: 21 mm. Colombia.

ino. **E. ino** Druce has an entirely unicolorously fawn-coloured body with a light yellow anal tuft. Forewings light fawn-coloured with darker brown veins and 2 narrow, brown, transverse lines, the first one near the base, the 2nd at the cell-end. Hindwings whitish diaphanous, apex and margin brownish. Expanse of wings: 42 mm. Colombia.

mizar. **E. mizar** Druce. Head and collar brownish-white, thorax and abdomen dark brown, the 2 last rings orange; venter banded white. Forewings grey-white, clouded in a darker brown, with dark brown veins. Hindwings dark brown, towards the base lighter. Expanse of wings: 40 mm. Ecuador.

resina. **E. resina** Druce. Anterior body grey, abdomen black, legs brownish black. Forewings grey-white, strewn with a darker grey, in the cell with a round, dark-grey spot; a dark-grey zigzag-line runs from the apex to the proximal angle. Hindwings dark grey. Expanse of wings: 44 mm. Colombia.

ignotum. **E. ignotum** Druce. The body is unicolorously brownish-grey, the legs whitish. Forewings whitish, densely dusted with a dark grey. Hindwings diaphanous white, at the margin broad black. Expanse of wings: 42 mm. South East Peru.

irrorata. **E. irrorata** Schaus. Palpi and forehead whitish; neck, collar, and thorax light brown: a white stripe extends from the base of the antennae to the base of the wings. Abdomen light brown towards the base, more grey posteriorly. Forewings brown, finely watered with black, behind the middle condensed to an

indistinct transverse shade and marginal streaks; a black discal spot. Hindwings dark grey, towards the base lighter. Expanse of wings: 21 mm. Cuba.

E. testaceum *Druce*. The body is grey, the antennae black. Forewings diaphanous white, behind the cell, at the apex, distal and proximal margin clouded grey. Hindwings diaphanous white. In the ♀ the metathorax is whitish-haired. Expanse of wings: 40 to 46 mm. Venezuela.

E. zephyrum *Schaus*. Anterior body grey-white, hindhead and neck like the abdomen above yellow, the latter above with subdorsal grey stripes, the two last segments all grey, beneath grey. The white forewings have grey veins and stripes on the cellular and submedian folds; anterior transverse line dentate; the posterior one, encircling the large discal spot, runs from the upper median vein to the middle of the proximal margin; behind it a large, white area with likewise white veins, in the apex and at the anal angle a greyish-spotted obscuration. The hindwings semi-transparent, iridescent, with a narrow, dark border. From Costa Rica. — **songoense** *subsp. nov.* (25 h) has above a quite unicolorous grey abdomen, being all white beneath; the cellular and submedian folds are not striped grey, but the veins are grey-brown also in the marginal area, at any rate all the markings brownish. Bolivia (Rio Songo), from BANG-HAAS.

E. aetolia *Druce* has a dark grey anterior body; the neck is bordered with white; abdomen above black, beneath dark grey, the anal tuft is light yellow. The forewings are grey-brown, at the base the costal and distal margins are striped white, the proximal margin in its whole extent bordered with white. Hindwings diaphanous blackish, in the disc lighter, with white fringes. Expanse of wings: 26 mm. Colombia.

E. phaeoproctum *Hmps.* (= *costulatum* *Druce* nec *H.-Schäff.*) resembles *aroa*; it is somewhat smaller and has a pronounced dark middle spot at the cell-end, the light, arch-shaped band before the apex is considerably narrower and the abdomen in both sexes unicolorously brown-grey. Distributed from Mexico to Panama.

E. venosa *Schaus*. Body blackish-brown; forehead whitish; in the neck 2 orange spots; an orange stripe below the collar and on the shoulder-covers. The first abdominal rings are white underneath. Forewings whitish, with broadly grey-striped veins, cellular and submedian folds, except on a large, round, white spot behind the cell; the basal half of the costal margin and the proximal margin are orange; at the cell-end and behind the white spot there is more densely grey dusting. Hindwings light blackish-brown, towards the margin darker. Expanse of wings: 23 mm. Costa Rica.

E. intranotatum *Dogn.* Body blackish-brownish; 2 spots on the neck, and the borders of the shoulder-covers are of a bright yellow, the anal apex blackish-brown; the first abdominal rings beneath whitish. Forewings yellowish-white, the veins and the distal two thirds of the costa broadly blackish-brownish; behind the cell is an oval white spot, extending from the subcosta to the lowest radial. Hindwings pale blackish-brown, in the disc diaphanous. Expanse of wings: 26 mm. Ecuador (Loja).

E. pomatinum *Druce* (26 i) is coloured light grey-brown on the body and forewings, on the latter mixed with reddish-brown; above the proximal margin there is a brown stripe, before the middle a curved, dark line, at the transverse vein a spot extending as far as the costa, and behind the middle a faded, broad, blackish-brown oblique band from the apex to the proximal margin, with an indistinct, light, undulate, antemarginal line and a blackish spot behind it at the proximal angle. Forewings light grey-brownish, towards the margin darker. Expanse of wings: 26 mm. Panama.

E. birchelli *Druce*. Anterior body light brown, abdomen darker, more blackish-brown. Legs light brown, curled white. The forewings are light brown, strewn with a darker brown, with a black spot at the cell-end. Hindwings diaphanous blackish-brown. Expanse of wings: 34 mm. Colombia (Bogotá).

E. plumbicollum *Hmps.* (25 i) is easily recognizable by the silvery-blue colour on the forehead, vertex, collar and prothorax. The animal is otherwise dark chocolate-brown, on the forewings with whitish diffuse spots below the base of the cell, in the cell-end and towards the margin between the inner-marginal vein and lower radial. Hindwings blackish-brownish, towards the base more thinly scaled. Expanse of wings: 36 mm. Brazil (Sa. Catharina).

E. lineatum *Dogn.* has a reddish-brown head and thorax, mixed with white. Abdomen blackish-brown, anteriorly and posteriorly with interspersed whitish scales, with whitish lateral spots and ventral bands. Forewings whitish, thinly scaled; near the base a short, reddish-brown band; 2 antemedian, irregularly dentate lines; at the cell-end a spot in the shape of an 8; 2 postmedian dentate transverse lines, the distal one thickened to a spot at the costa and proximal margin, and a similar, antemarginal line thickened also in the middle; a marginal line and dots at the ends of the veins. Hindwings hyaline with a brownish border and veins. Expanse of wings: 46 mm. Ecuador; Bolivia.

E. hoffmannsi *Rothsch.* is much smaller than the preceding. The forewings are not semi-diaphanous whitish, but light yellow-brownish, the markings much less distinct and of a dull wooden-brown colour, not chocolate-brown. The last abdominal ring is of a bright yellow, not dirty-brown. Length of forewings: 20 mm. Peru; Ecuador.

- rothschildi*. **E. rothschildi** *nom. nov.* (= *ockendeni* *Rothsch.* nec *Druce*) (25 i) greatly resembles the preceding, being likewise smaller than *lineatum*, with yellowish-grey, semi-diaphanous wings, with faded pale grey-brown markings which have almost vanished in the basal half. Venezuela; Ecuador; Peru.
- discolor*. **E. discolor** *Wkr.* (= *rububa* *Druce*) (25 i) has brownish-white forewings with faded, grey-brown spots; the largest occupies the middle of the costal margin and encloses a roundish, light spot at the cell-end; further spots are at the apex, in the middle of the distal margin and at the proximal angle. The pale hindwings exhibit a somewhat darkened margin. Head, thorax and abdomen brown-grey, on the forehead a metallic blue spot. Widely spread from Mexico through the whole of Central America and Brazil as far as Bolivia.
- zizana*. **E. zizana** *Dogn.* Head and thorax brown, forehead blue. Forewings light grey, traversed by 4 lighter veins, the 2 proximal ones regular and parallel, the 2 distal ones more irregular and with several white spots. Hindwings whitish, at the apex and margin smoky brownish. Expanse of wings: 30 mm. Ecuador (Loja).
- nervulum*. **E. nervulum** *Rothsch.* Body sooty wooden brown, on the head with a blue lustre; venter beneath in the basal half whitish. Forewings dirty white with brown veins and large, cloudy, dark brown spots in the disc and at the apex. Hindwings diaphanous grey, in the distal quarter darker. Length of forewings: 15 mm. Ecuador.
- nubilosum*. **E. nubilosum** *Rothsch.* somewhat resembles *nervulum*, of a deeper purple brown on the body, the head black with a blue lustre. The forewings are brownish white in the smaller basal half, with a darker brown base and some indistinct, small stripes; the distal two thirds are purple-brown, in the most distal third clouded whitish. Hindwings diaphanous whitish, at the apex dark grey. Length of forewings: ♂ 13,5 mm, ♀ 17 mm. Peru; Venezuela; Sa. Martha.
- carabayana*. **E. carabayana** *Schaus.* Head grey, palpi and antennae black, forehead metallic dark blue; thorax grey, marked brown. Abdomen in the basal half grey, at the end black. Forewings grey, sparsely strewn with brown, with blackish-brown markings; a shade at the base, a transverse antemedian band, a broad shade from the cell-end to the costa, behind it a line running in an arch round the cell, being the thickest at the proximal margin, a broad antemarginal shade, interrupted between the lower radials, at the margin spots at the apex, between the lower radial veins and at the proximal angle. Hindwings white, at the costa and apex blackish-brown. Expanse of wings: 35 mm. Peru.
- sordidescens*. **E. sordidescens** *Rothsch.* has duller, darker forewings than *carabayana* with obsolete markings. The head is blue, thorax and abdomen sooty wooden brown, the venter beneath in the basal half whitish. Forewings pale wooden brown, in the distal two thirds with darker brown spotted clouds. Hindwings diaphanous light wooden brown. Length of forewings: 19 mm. Venezuela; Peru.
- coeruleocaput*. **E. coeruleocaput** *Rothsch.* is considerably larger than the preceding. The head is metallic blue, the thorax dirty greyish-white, bordered with a sooty black; the abdomen is above light sooty blackish, beneath in the basal half all white, the posterior rings black, with white bands. Forewings creamy white, strewn with brown scales, veins and basal area blackish-brown. An irregularly spotted, dark brown oblique band extends from $\frac{1}{4}$ of the length of the costal margin to the proximal angle and gets much broader below the median; some more deep brown spots are at the transverse vein and above it, at the apex and between the upper median and middle radial vein. Hindwings whitish diaphanous, at the border and apex dark grey. Length of forewings: ♂ 24 mm, ♀ 26 mm. Peru.
- nebulosum*. **E. nebulosum** *Dogn.* (25 g) has a dark brown body, with a somewhat lighter abdomen, forehead blue. Forewings dark brown with a faded, grey antemedian band; behind the cell a similar one, interrupted between the median veins, turning inward on the lower median vein as far as the cell-end. Antemarginal spots above the middle and 2 at the proximal angle. Hindwings diaphanous light brownish, at the margin and apex browner. Expanse of wings: 44 mm. Ecuador (Loja).
- album*. **E. album** *Druce* (= *agylloides* *Dyar*) (25 k) is of a pure white, strikingly resembling some American *Agylla*-species; only the teeth of the antennae are blackish. Hitherto known only from Mexico: Jalapa, Orizaba, (January), Mirador (March, April).
- vestale*. **E. vestale** *Schaus* (24 k) is larger and with broader wings than the preceding, likewise unmarked white, but the wings more thinly scaled, semi-diaphanous, and with a slight greenish silvery gloss. From Peru, São Paulo, and Rio Grande.

146. Genus: **Metaerocea** *Dyar*.

Distinguished from *Eucereon* by the 2nd abdominal ring being strangulated. The veins are, on the whole, the same; on the forewing, the 1st subcostal vein comes from the upper cell-angle. On the hindwings the subcostal vein rises on a short pedicle with the uppermost radial.

M. postflava *Schaus.* Head, thorax, and the base of the abdomen are black; the rest of the abdomen *postflava*. is orange-yellow above, brown beneath. The blackish-brown forewings with darker veins; at the base and middle of the proximal margin and antemarginally there are darker shades, at the costal margin before the middle a dark spot. Hindwings black with hyaline stripes in the disc. Expanse of wings: 29 mm. Rio de Janeiro.

147. Genus: **Apocerea** *Dyar.*

Likewise very near to *Eucereon* from which it differs by the uppermost subcostal vein of the forewing rising on a joint pedicle together with all the others; the upper radial comes from far below the upper cell-angle. On the hindwing, the upper median vein, the lower and middle radial vein, all come forth separated from near the lower cell-angle. The upper radial vein and the subcostal likewise rise separated from the upper cell-angle.

A. sobria *Schaus.* Head and thorax dark grey, the neck yellow. The abdomen is above black, the *sobria*. 3 last rings, with subdorsal interruptions, banded yellow, anus yellow. Forewings light grey with dark grey veins; antemedian and postmedian, curved transverse lines, the latter being dentate towards the proximal margin; between the veins darker stripes. Hindwings greyish-black, at the base whitish. Expanse of wings: 26 mm. French Guiana.

148. Genus: **Correbia** *H.-Schäff.*

Large, rather slender species with narrow wings, mostly coloured orange and bluish-black; the abdomen exhibits short hair-tufts at the sides and at the end; the long palpi are porrect, the terminal joint turned somewhat downward. On the forewing, the upper median vein proceeds from the lower cell-angle, the lower and middle radial on a long pedicle from it. On the hindwing, the upper median vein rises before the lower cell-angle, whereas the lower and middle radial rise together, or on a short pedicle likewise from the lower cell-angle or above it. The *lycoides*-group most strikingly copies the genus of beetles *Colobothea*.

C. bricenoi *Rothsch.* has the broadest forewings of all the species known. Head and thorax are of a dull *bricenoi*. orange-brown, forehead and vertex spotted black, thorax with a black median line. Palpi and antennae, abdomen and underside sooty black. Forewings orange-brown, a transverse antemedian band from the costa to the inner-marginal vein, the middle third of the proximal margin and the apical fifth are black. Hindwing sooty black, in the basal half semidiaphanous, at the costal margin 2 yellow spots. Length of forewings: ♂ 21 mm, ♀ 22 mm. Venezuela.

C. oberthueri *Hmps.* (= *lycoides* *Oberth.*) (25 k) greatly resembles the following species, being recogni- *oberthueri*. zable by the black parts of the wings exhibiting minute, vertical dashes of a silvery blue, as well as by the black abdomen being partly suffused with blue. From Peru and Bolivia.

C. lycoides *Wkr.* (25 k). This species initiates a small group of very similar species which are not *lycoides*. easy to discern, what is rendered still more difficult by the great variability. *lycoides* has narrower wings, coloured more yellow-brown; the discal band and the apical spot are of a rather pure dull black without the distinct, bluish-grey dusting in the cell-spaces; the apical spot does not extend as far as the proximal angle, but it is mostly rectilinearly cut off on the lower or already on the upper median vein. The margin of the rather light, diaphanous hindwing is narrow. The abdomen is above always black, the brown-yellow lateral stripe narrow. Very widely distributed from Mexico to Paraguay; also in Cuba and Jamaica. — In the form **ceramboides** *ceramboides*. *H.-Schäff.* the ochreous-yellow colour is shaded by dark brown.

C. intermedia *nom. nov.* (= *elongata* *Rothsch.* nec *Dogn.*) is about between *lycoides* and *undulata*; it *intermedia*. has the black upperside of the abdomen and the narrow shape of the wings of *lycoides*, whereas the colouring of the wings is more like *undulata*. The sides of the 1st ring and a narrow lateral line from the segments 2 to 5 are orange-brown. The black apical spot of the forewing is striped dull bluish-grey. Length of forewings: ♂ 25 mm, ♀ 27 mm. Brazil (Sa. Catharina; Petropolis; Rio de Janeiro). — subsp. **boliviana** *Rothsch.* differs *boliviana*. by broad orange lateral stripes on the abdomen, a paler, more tawny ground-colour of the forewings, and an entirely black apical spot without any grey longitudinal stripes. Bolivia.

C. undulata *Druce* (25 k) differs from *lycoides* by the forewings being somewhat broader, the ground- *undulata*. colour of a more orange tint, the black parts striped bluish-grey; the hindwings towards the margin blacker. On the whole, the orange colour on the abdomen is more extensive, and in the nomenclatural type, the lateral stripes on the 3rd and 4th rings are united to a yellow transverse band. But in a very great number of specimens from Mexico lying before me, I find all the transitions from the abdomen being above entirely black, as in

- nigridorsalis*. *lycoides*: **nigridorsalis** *form. nov.*, to an almost entirely orange-yellow abdomen, on which only the last segments remain black: **flavidorsalis** *form. nov.* (25 l). — Mexico to Guatemala.
- flavidorsalis*. **C. obtusa** Druce (25 l) is exteriorly almost just like the preceding, from which it differs by entirely yellow palpi, legs, and underside, which are black in the other species. The hindwings are much more extensively hyaline diaphanous. Guatemala, Venezuela (Merida).
- semitransversa*. **C. semitransversa** Schaus. Head and thorax black. Vertex, neck and base of shoulder-covers spotted ochreous-brown. Abdomen black, lateral stripes and the underside except the 2 last rings ochreous-brown. Forewings ochreous-brown with a black discal band as far as the submedian and a black apical spot striped bluish-grey as in *obtusa*. Hindwings transparent blackish-brown with black veins and distal margin, the costal margin being spotted yellow. Expanse of wings: 39 mm. Costa Rica.
- agnonides*. **C. agnonides** Druce (25 l) has much more extensively yellow forewings than the allies: the black apical spot only extends to the upper median vein, on the lower radial the yellow ground-colour penetrates far into it. In the middle of the cell there is a roundish black spot, below which and at the proximal margin there is yet some dark shading. Nicaragua, Peru.
- rufescens*. **C. rufescens** Rothsch. (25 l) is distinguished by the deep orange-red-brown colour of the forewings, the marking being similar as in the preceding species, but the discal band consists more of a black costal spot, being rounded off below and slightly touching the broadly black proximal margin; in the apical spot lavender-blue stripes; the hindwings are almost entirely black; the abdomen shows an intense steel-blue lustre. Venezuela, Colombia (Muzo).
- fulvescens*. **C. fulvescens** Dogn. (25 l) is distinguished by rather thinly scaled, blackish-brown forewings, only the base, the whole costal margin, the median and vein 1 being dull red-brown; hindwings blackish, semi-diaphanous, costa red-brown. On the under surface the wings are blackish-brown with broad orange costal margins. Body bluish-black, head, collar, thorax, and the ventral side of the 3 first abdominal rings red-brown. Forehips orange, legs black, spotted white. Panama (Lino).
- affinis*. **C. affinis** Druce (26 b) on the orange wings exhibits only a roundish, bluish-black apical spot; the hindwing is hyaline in the basal half, orange at the costal margin, with a blackish-brown border. The abdomen is black, laterally striped orange, but not as far as the end; the first 4 rings are beneath orange. Mexico, Guatemala.
- raca*. **C. raca** Druce (26 m). Head, legs and abdomen are black; vertex, palpal base, thorax, spots on the legs, lateral stripes and the underside of the 1st to 5th rings orange. Tarsi ringed white. Forewings all orange with black fringes. Hindwings semi-diaphanous, towards the margin blackish, at the costal margin orange. Expanse of wings: 40 mm. Panama (Chiriqui).
- flavata*. **C. flavata** Druce. Head, abdomen and legs are black, the latter ringed white; hindhead, collar and thorax orange-red. Forewings orange, hindwings black, towards the base hyaline. On the under surface, both wings are black, only the base and costal margin of the forewing are orange. Expanse of wings: 46 mm. Colombia.
- germana*. **C. germana** Rothsch. is larger than *minima*, of a lighter colour, with a much broader yellow base and transverse band of the forewing. Length of forewings: 14 mm. Venezuela; Ecuador; Peru; Bolivia.
- minima*. **C. minima** Druce (26 a). This very small species in its exterior exactly resembles a *Correbidia terminalis*, but it is only half as large. Venezuela; French Guiana.
- felderi*. **C. felderi** Rothsch., according to the short description, greatly resembles *minima*, but it is much darker, with a much narrower transverse band and almost entirely absent orange colouring at the base. It may be identical with the following? Amazon.
- obscura*. **C. obscura** Schaus. The body is black; an orange stripe extends from the antennae across the collar to the shoulders. Palpi at the base and near the tips yellow. Femoral base white and yellow, legs otherwise black, tarsi ringed yellow. The black forewings exhibit a postmedian, yellow-reddish transverse band being brown below the cell, extending from the costa to the proximal margin. Hindwings diaphanous blackish, with darker veins, costal and distal margin. Expanse of wings: 20 mm. French Guiana.
- elongata*. **C. elongata** Dogn. (26 a). Head black and blue; thorax and abdomen brick-red, shoulder-covers brown; legs brown with red femora. The venter shows a series of white dots. Forewings red-brown with a yellow, triangular inner-angular spot. Hindwings hyaline with blackish-brown veins and marginal band. Expanse of wings: 34 mm. Loja (Ecuador).

149. Genus: **Correbidia** *Hmps.*

The species greatly resemble those of the preceding genus, except the broader shape of the wings and the costal margin being very much bent, but there occur transitions, and the veins being not constant at all in long series of specimens, the termination is rather dimmed. The upper median vein of the forewing recedes from the lower cell-angle, and the pedicle of the lower and middle radial disappears more or less, whilst on the hindwing the upper median vein and lower radial approach each other, the middle radial rising in a bent shape from above the cell-angle.

C. notata *Btlr.* (26 a) is easily recognizable by the blackish-brown forewing with a diaphanous, whitish *notata*. postmedian band extending only to the lower median vein and being tinted yellow towards the costa, with a yellowish spot below it and one at the costal base. Hindwing diaphanous black-brownish, towards the base whitish. On the blackish-brown body the palpal base, sides of the head, collar, hips, and lateral stripes on the first abdominal rings are orange-yellow, of the same colour is the ventral side on the first rings, which are then followed as far as the end by sublateral stripe-like spots. Expanse of wings: 26 mm. Amazon.

C. assimilis *Rothsch.* resembles *notata* (26 a) from which it differs by the base of the forewing being *assimilis*. much more extensively reddish-brown, and by a buff, not whitish band of the forewing.

C. similis *Rothsch.* resembles the two preceding species, but it is much larger, and the basal area and *similis*. band of the forewing are much more extensive and more red-brownish. Venezuela; Peru; Trinidad.

C. steinbachi *Rothsch.* is still larger than *similis*, the ground-colour of the forewing varying from *steinbachi*. buff to orange-brownish; the black band of the forewing and the apex are more indistinct and more or less obsolete. Length of forewings: 17 mm. Bolivia, Amazon (Fonte Boa).

C. simonsi *Rothsch.* resembles the preceding, but the black transverse band and the apex are distinctly *simonsi*. prominent and sharply defined, the ground-colour pale reddish buff. Bolivia and Peru.

C. tristitia *Kaye.* Palpi black, 1st and 2nd joint below ochreous-yellow; forehead and neck ochreous- *tristitia*. yellow, mixed with a dull brownish-black; base of shoulder-covers ochreous-yellow, behind it dark brown. On the forewing the base, a broad band, and an apical spot are purple black; a basal band and a postmedian one are yellow; the latter is expanded towards the proximal margin and is undulate on the upper median vein. Hindwing diaphanous dull-ochreous-yellow with a triangular, dark spot at the costa; distal margin purple black. Expanse of wings: 33 mm. British Guiana. In this species, being unknown to me, the description of the abdomen is absent.

C. calopteridia *Btlr.* (26 a) differs from *notata* by its paler yellow and reduced ground-colour; the *calopte-* base of the forewing is black, the last abdominal rings are beneath yellow except the anal apex remaining black. *ridia*. French Guiana; Pará; also from Peru (Chanchamayo and Pachitea).

C. klagesi *Rothsch.* is distinguished from *calopteridia* (26 a) by much longer and narrower forewings, *klagesi*. with a much lighter, whitish base and transverse band, the ground-colour being much bluer. Venezuela, Surinam; Amazon (Fonte Boa, Codajas, Iquitos).

C. terminalis *Wkr.* (= *cimicoides* *H.-Schäff.*, *calopteridia* *Druce* nec *Btlr.*). The name-type from *terminalis*. Cuba has orange-yellow forewings with a narrow discal band and apical spot of a bluish-black colour. — In the common continental form **continentalis** *subsp. nov.* (26 a) from Mexico to Venezuela, the discal band is *continen-* broader, the proximal margin being also darkened brownish-black. The bases of the wings remain orange, *talis*. the abdomen is black beneath at the end.

C. elegans *Druce* (26 b). The forewing is reddish orange with a black apical spot, the hindwing semi- *elegans*. transparent with a broad, brownish-black marginal part. Head and thorax orange, abdomen blackish-brown with orange lateral stripes. Occurring in Mexico, Costa Rica, and Panama. — In subsp. **meridionalis** *Rothsch.* *meridiona-* the veins and margins of the black apical spot by the deeper orange-brown colour contrast with the lighter *lis*. ground. Ecuador.

C. costinotata *Schaus.* Head and thorax orange-yellow, forehead, antennae, and a median stripe on *costinotata*. the thorax black. Abdomen and legs black, hips, bases of femora, and a lateral stripe on the 3 first rings orange-yellowish. Forewings brownish orange with a large, purple black apical spot being proximally irregularly defined, and a small black spot at the middle of the costal margin; at the base of the proximal margin a black stripe. Hindwings yellowish-white, the proximal and distal margins suffused with blackish. Expanse of wings: 33 mm. Costa Rica.

C. striata *Druce* (26 a) is immediately recognizable by the reddish-orange forewings growing somewhat *striata*. darker towards the margin and exhibiting here, between the lower radial veins, a black streak; the middle of the proximal margin is black. Nicaragua; Panama.

apicalis. **C. apicalis** Schaus. Antennae black; palpi black, at the base ochreous-yellow. Forehead black. Hind-head and thorax ochreous-yellow with a black median line. Abdomen above and beneath black, at the sides broadly ochreous-yellow. Forewings of a brilliant ochreous-yellow; a broad, bluish-black, antemedian spot extends from below the costal margin to the inner-marginal vein; at the apex an oblong, bluish-black spot. Proximal margin and the adjoining veins orange. Hindwings yellowish, thinly scaled, apex and proximal angle blackish. Expanse of wings: 25 mm. Cuba.

150. Genus: **Scepsis** Wkr.

Very near to the genus *Ctenucha* from which it differs by the palpi being somewhat shorter with a straightly porrect terminal joint, and by the long, narrow wings; the shaft of the antennae in the middle a little thicker.

fulvicollis. **S. fulvicollis** Hübner. (= *semidiaphana* Harr.) (26 a) has an orange-yellow palpal base, vertex and collar, the abdomen being bluish-black. The long extended forewings are brown, the hyaline hindwings have a broad, bluish-grey border. United States. — In the form **pallens** Hy. Edw. the orange-yellow parts on the head and thorax are yellow.

packardi. **S. packardi** Grote (= *mathewi* Hy. Edw.) deviates from the preceding by browner forewings and the pale yellow colour of the hindhead extending anteriorly as far as between the antennae. United States. — *cocklei*. v. **cocklei** Dyar. In British Colombia there flies a local race, the colouring of which is more like that of *fulvicollis*: forewings of a duller blackish, in the disc diaphanous.

wrighti. **S. wrighti** Stretch (26 b) deviates from the preceding by the blackish-brown colour of its body, the head being all black, the collar and shoulders entirely pale yellow, in f. **gravis** Hy. Edw. orange. California.

discopuncta. **S. discopuncta** Hmps. Body pale ochreous-yellowish, mixed with blackish-brown, vertex striped black, so is the distal margin of the shoulder-covers and the thorax; neck orange. Abdomen above blackish, except the last ochreous rings. Forewings pale ochreous-yellow with black stripes in the base of the cell and above the submedian fold, as well as black dots in the middle of the cell, in the corners of the cell, and behind the cell; postmedian and antemarginal rows of dots being confluent to streaks towards the costa. Hindwings transparent, brownish towards the margin. Expanse of wings: 48 mm. Bolivia.

subhyalina. **S. subhyalina** Hmps. Head white, spotted black on the forehead and vertex; the rest of the body is pale ochreous-yellow, on the metathorax and at the sides of the abdomen spotted black. Forewings diaphanous ochreous-yellowish with dark, faded discal and antemarginal lines. Hindwings more whitish. Expanse of wings: 40 mm. Bolivia.

151. Genus: **Propyria** Hmps.

Small Lythosid-like species with short palpi being turned downward, the antennae being serrate-dentate in the ♂. The lower and middle radial veins of the forewing stand on a long pedicle, the upper one rises below the upper cell-angle; on the hindwing the upper median vein and the middle radial are pedicelled, the lower radial being absent.

schausi. **P. schausi** Dyar (= *fulgens* Neum. & Dyar) has a black head and abdomen, whilst the collar and thorax are carmine. Forewing carmine with a black distal margin occupying one fifth of the length of the wing. Hindwing black with a red basal half of the costal margin. New Mexico; Arizona.

ptychoglene. **P. ptychoglene** Hmps. (= *aequalis* Druce) (26 c). Body black with red shoulder-covers. The forewings are scarlet with a black distal margin which grows broader towards the proximal margin and extends almost to the base, extending towards the costal margin as a fine costal stripe to about the centre of the wing. The hindwings are black, the basal two thirds of the costal margin scarlet. Found in Mexico and Guatemala.

normani. **P. normani** Schaus. Body black, shoulders carmine. Forewings leaden black with a broad red stripe from the base of the costa along above the submedian, growing narrower towards the apex; apical third of the costal margin narrowly black. Hindwing purple black, at the costa some red. Expanse of wings: 24 mm. Costa Rica.

ockendeni. **P. ockendeni** Rothschild. Head and thorax timber-coloured, chest whitish; abdomen black with subdorsal rows of orange-red spots. Forewings reddish timber-coloured; apical fourth, a discal spot, and the proximal margin purple brown. Hindwings orange-scarlet with a black margin, at the proximal margin and anal angle broader. Length of forewings: 15 mm. Peru.

nigrirufa. **P. nigrirufa** Rothschild. Head and thorax sooty brown, abdomen black. Forewings timber-coloured. Hindwing in the basal half sooty black, in the apical half carmine, bordered with black. Length of forewings: 16 mm. Peru.

P. atroxantha *Schaus* deviates from the diagnosis of the genus by the absence of the 4th subcostal vein, whilst the upper radial is petioled with the 3rd and 5th subcostal vein. Body black, margins of the eyes, shoulder-covers, a stripe on the thorax and subdorsal lines on the 2 first abdominal rings are orange-yellow. Wings orange-yellow, the apical third of the forewing and a narrow proximal margin black. Hindwing with a black border, extending at the proximal margin as far as to its middle, where it suddenly ends. Expanse of wings: 22 mm. Mexico (Misantla). *atroxantha*.

P. albofasciata *Rothsch.* is a very large, entirely different species. Head and thorax black with a blue lustre, neck orange. Abdomen black with metallic blue rings and blue sublateral stripes. Forewing sooty black with a white, somewhat oblique, antemedian transverse band and a blue dot at the base. Hindwing black with a broad white transverse band extending from the costa to the lower median vein. Length of forewings: 18,5 mm. Peru (Chanchamayo). *albofasciata*.

152. Genus: **Lycomorpha** Harr.

Like the preceding genus, it greatly reminds us of the Lithosid genus *Ptychoglene*. The palpi are straightly porrect, the shaft of the antennae somewhat thicker in the middle. The two lower radial veins of the forewing rise unpetioled. The hindwing, between the proximal angle and the middle radial, exhibits a concave indentation, the lower radial is absent, the middle one rising above the lower cell-angle.

L. grotei *Pack.* (= *palmerii* *Pack.*) (26 c) is recognizable by the red thorax and collar; the hindwings are more or less extensively red, in f. **pulchra** *Dyar* all red except black fringes and an entirely narrow marginal line. Western United States. *grotei*. *pulchra*.

L. fulgens *Hy. Edw.* (26 c) differs from the preceding by the black collar and thorax, only the shoulder-covers being red; the red spot of the hindwing is more confined to the costal margin and irregularly defined. New Mexico; Arizona. *fulgens*.

L. drucei *Hmps.* is jet-black. The forewing shows a large, earmine spot extending from the base as far as beyond the middle, from the subcosta to the inner-marginal vein. On the hindwing, the basal half of the costal margin is carmine. Expanse of wings: 28 mm. Mexico (Durango). *drucei*.

L. pholus *Drury* (26 d) has an orange-yellow basal part of both wings. The distal part is black like the body, only the shoulder-covers are orange. Canada; United States. — subsp. **miniata** *Pack.* from California shows the orange colour of a more rosy tinge and much more extensive. — The larva is greyish-brown, watered greenish, blackish-haired with large, pale yellow dorsal spots from the 4th to 10th rings, on the others with smaller whitish spots. It lives on lichens, on which it is difficult to notice, and changes to a light brown pupa in a thin web. *pholus*. *miniata*.

153. Genus: **Ctenucha** Kirby.

Broad-winged, often very variegated species with a relatively slim body. The palpi, with a terminal joint begone turned downward, project beyond the head; shaft of antennae not thickened, in the male combed. On the forewing, the upper radial vein rises below the upper cell-angle; on the hindwing, the upper median vein rises, together with the two lower radials from the same place of the lower cell-angle, or separately.

C. togata *Druce* (= *augusta* *Hy. Edw.* (26 c) is not to be mistaken by the forewings being almost quite earmine except a narrow black border; the hindwings are black, at the costal margin narrowly red. Mexico, Costa Rica, Guatemala, Panama. — subsp. **schausi** *Rothsch.* has scarlet, not black shoulder-covers and scarlet, not carmine wings. Mexico (Epinal). — **obscurata** *form. nov.* (26 d) from Costa Rica has the disc of the forewing very much dusted black. *togata*. *schausi*. *obscurata*.

C. cyaniris *Hmps.* (26 d). Both pair of wings are black, in the basal halves with a metallic blue lustre, like the whole body. The forewings show in the middle of the wing an orange-yellow transverse band, which is usually longer and broader in the female. The hindwing shows an orange-yellow spot beyond the middle of the costal margin. The species occurs in Ecuador. *cyaniris*.

C. popayana *Dogn.* differs from *cyaniris* by the orange-yellow spot on the forewing being twice as broad; palpi at the base anteriorly white; ventral side striped black and white. The basal blue on the wings is somewhat confined. May be identical with the following. Colombia. *popayana*.

C. garleppi *Rothsch.* according to the description, differs from *cyaniris* by the smaller extent of the blue colour, which is darker and duller, and by the extraordinarily broad orange band of the forewing, which *garleppi*.

occupies also the apical third of the hindwing and is bordered with black. I presume that it coincides with *popayana* as a synonym. Peru.

- refulgens*. **C. refulgens** Dogn. (26 d) differs from *cyaniris* by the absence of the orange-yellow spot of the hindwing; that of the forewing in both sexes neither reaches the costal margin nor the proximal angle. The underside is, like in the preceding species, extensively white in the ♂, in the ♀ more metallic blue. Ecuador; Peru (Marcapata).
- aymara*. **C. aymara** Schaus. Black; palpal base, forehead and chest white like the underside of the abdomen. Metathorax and abdomen above suffused with blue, the latter with an orange dorsal stripe. Forewing at the base and proximal margin blue, in the middle with a large orange spot. Hindwing at the base suffused with blue, in the ♂ with a large orange spot before the apex, extending down as far as the upper median vein. The ♀ is destitute of this spot and all the white markings. Expanse of wings: ♂ 28 mm, ♀ 32 mm. Peru.
- mennisata*. **C. mennisata** Dogn. greatly resembles the preceding, but the wings are a little narrower and longer, the yellow spot of the forewing does not extend beyond the basal half of the wing, on the hindwing the yellow apical spot is absent, as well as the orange-scaled dorsal stripe on the abdomen. Expanse of wings: 27 mm. Bolivia.
- albipars*. **C. albipars** Hmps. Dull black, forehead, vertex and metathorax spotted metallic blue; abdomen above with a blue lustre, beneath at the base a white spot. The forewings exhibit an orange-yellow discal band. Forewing white, in the marginal third black, towards the costa somewhat broader. Expanse of wings: 32 mm. Bolivia.
- biformis*. **C. biformis** Dogn. Body black, above with an intense bluish-green metallic lustre; hips and venter white. Forewing blackish-brown with a broad oblique band from the middle of the subcostal to the proximal angle, not quite reaching them, the one in the ♂ being of a deep red, in the ♀ orange-yellow; at the base and behind the oblique band between and above the median veins, there are metallic blue stripe-like spots. Hindwings blackish-brown with a dark blue lustre. Ends of fringes whitish. Expanse of wings: 27 mm. Peru (Cajon).
- nantana*. **C. nantana** Wkr. (= *rubicunda* Dogn.) has a stout, blue, densely black-haired body. The black forewings are green at the base, a subcostal band and a marginal band being pale yellow. The hindwings are scarlet with a black base and marginal band and pale yellow fringes. Length of forewings: 30 mm. Amazon.
- annulata*. **C. annulata** Schaus. Head and thorax metallic blue, forehead white, palpi black. Abdomen black, at the base suffused with blue, above yellow, beneath curled white. Wings black, towards the base suffused with metallic blue. Forewing with a broad, orange oblique band; hindwing with an orange marginal band, strewn somewhat with blackish. Expanse of wings: 28 mm. Bolivia.
- braganza*. **C. braganza** Schaus. Black; head and thorax mixed with brown; palpal base, and the sides, sometimes also the whole neck orange. Abdomen with a blue lustre; hips, femora and venter, the latter sublaterally, striped white. Anus sometimes orange. The black forewings show lighter, brownish veins with a postmedian, white oblique band varying in extent; fringes at the apex white. Hindwings with a blue lustre, with blackish-brown veins and white fringes. Expanse of the wings: 48 mm. Brazil (Theresopolis; Rio de Janeiro).
- circe*. **C. circe** Cr. (= *affinis* Bsd., *pylotis* Möschl.) (26 d) is smaller than the preceding and differs by white transverse bands on the ventral side of the abdomen, not 2 white longitudinal lines. Besides, the front of the palpi and parts of the forehead are white, the shoulder-covers and thorax striped lighter, the blackish-brown collar contains interspersed, orange-yellow hairs. All the rest like in *braganza*. Widely distributed from Nicaragua Ecuador, Venezuela, Surinam as far as São Paulo.
- palmeira*. **C. palmeira** Schaus differs from the two preceding by the brownish-black underside of the abdomen minus the white. On the abdomen the blue lustre is absent. The white band behind the cell is cuneiform and extends only from the lowest subcostal to the lower radial vein. The bluish-black hindwings exhibit a white apical spot. Expanse of wings: 40 mm. Brazil (Rio de Janeiro, Rio Grande do Sul); Paraguay.
- jonesi*. **C. jonesi** Rothsch. differs from *palmeira* by the white postmedian band being much longer, extending from the subcosta to the border above the lower median vein and not ending already at the lower radial vein. Paraná, taken in March.
- andrei*. **C. andrei** Rothsch. Chest and underside of abdomen brownish-black, forewings blackish-brown with lighter veins and an oblique white band from the subcosta behind the middle to the proximal angle. Hindwings blackish steel-blue with white fringes. Trinidad.
- mortia*. **C. mortia** Schaus. Head and thorax black; neck and palpal base orange, thorax finely striped yellow. Abdomen bluish-black with orange anal hair. Forewings black with grey veins and a large white spot behind the cell. Fringes at the apex white. Hindwings bluish-black with white fringes. Expanse of wings: 37 mm. Castro (Paraná).

C. reimoseri *Zerny* is allied to the preceding from which it differs by much narrower wings. By the *reimoseri*. white, almost circular spot of the forewing being not situate behind the cell, but in the cell-apex itself, it forms the transition to the following. The contours of the wings correspond about to those of *venosa*. Body and wings are black with a blue lustre; basal palpal joint, sides of the head, shoulders, and anus yellow. Expanse of wings: 32 mm. Paraguay.

C. semistria *Wkr.* (26 d) is black, on the abdomen and hindwings with a bluish-green lustre. The first *semistria*. palpal joints, the head behind the eyes, and the throat orange. The blackish-brown forewing exhibits a large, white spot at the cell-end, the hindwings a small one below the cell-end. Brazil (♂).

C. subsemistria *Strand* from Argentina is closely allied to the preceding. The hindwings are dull black *sub-semistria*. without a blue lustre; orange colour is also found on the shoulders, margin of the collar, and apex of the abdomen, as well as at the base of the forewing. Hindwing without a white spot, that of the forewing being much smaller. Expanse of wings: 32 mm.

C. editha *Wkr.* (26 e) is a relatively broad-winged species with intensely lustrous blue body and wings. *editha*. Palpal base, chest, venter, and the dorsum of the 2nd to 5th abdominal rings are scarlet. Known only from Hayti.

C. vittigera *Blanch.* (26 e) is one of the largest species: the dark brownish-grey forewings are veined *vittigera*. whitish, also the costal margin and subcosta being striped white; hindwings bluish-black with white fringes. The body is greenish-black, the abdomen with whitish ring-indentations. The head is orange, so are the margins of the collar and shoulder-covers. Brazil (Rio de Janeiro, Rio Grande do Sul), Chile, Argentina. — In *lativitta* *lativitta*. *Strand* (26 e as *albescens*), by the white colouring being more extensive, there remains but very little of the brown ground-colour. — f. *nivosa* *Wkr.* has the median veins and the submedian fold also on the hindwing *nivosa*. striped white.

C. devisum *Wkr.* (= *marita* *Schaus*) (26 e) is immediately discernible from among the similar species *devisum* by the white head being on the vertex usually more yellowish. The forewings are of a paler brown than in the allies, the veins white. Brazil, Argentina.

C. venosa *Wkr.* (26 f) has brownish-grey forewings with white to orange-yellow stripes on the inner- *venosa*. marginal vein, the median and the three radial veins. The hindwings are bluish-black. The body is black, suffused with metallic blue, the hindhead scarlet, the shoulder-covers are striped orange. A very common animal from North America, supposed to be distributed as far as Ecuador. How far the southern habitats refer to the forms of the following species is a mooted question. The southernmost habitat to be determined to a certainty by myself, is Mexico.

C. rubrovenata *Rothsch.* is smaller than *venosa*, the wings shorter and more obtuse, the head black, *rubrovenata*. only in the neck red; veins, and stripes on the shoulder-covers are orange-red, in the ♀ yellow; the lowest subcostal vein of the forewing, being always black in *venosa*, is here likewise orange. Bolivia (Rio Songo). — In *peruviana* *form. nov.* (26 f) from Peru the head is orange-red except a black stripe between the antennae. — In *peruviana*. *tucumana* *Rothsch.* from Argentina, being larger, all the veins of the forewing are prominently marked red *tucumana*. or yellow. — In *ecuadorica* *Strand* (= *venosa* *subsp.* 1. *Hmps.*) (26 f) from Ecuador, which is also before us *ecuadorica*. from Chanchamayo (Peru) and has likewise an entirely black head, the red in the neck having almost disappeared, the forewings are of a duller greyish-black, the veins are whitish-yellow as in *venosa*, the hindwings with an intense blue lustre.

C. reducta *Rothsch.* is larger than the preceding, with much broader wings. In the ♂ the inner-marginal *reducta*. vein and the median, the two median veins and the middle radial are scarlet or orange-yellow, in the ♀ white; the lower and upper radial veins remain black. The forewings are black, suffused with blue, not blackish-brown. Peru.

C. cressonana *Grote* is twice as large as the preceding. Head and thorax black, metathorax and abdomen deep blue. Palpal base, vertex, neck and stripes on the shoulders are orange; shoulder-covers black and blue, intermixed with some orange-yellow hairs. The black forewing is at the base blue; the costal margin, the median, the inner-marginal vein, the upper median and lower radial veins are coloured orange close to the margin. Hindwings deep blue. Fringes on all the wings white. Expanse of wings: 52 mm. Rocky Mountains. — In ab. *lutea* *Grote* the orange colouring is replaced by yellow, whereas *sanguinaria* *Streck.* exhibits scarlet *lutea*. colour instead. The latter is also found in Mexico. *sanguinaria*.

C. ruficeps *Wkr.* (26 e) has a metallic green abdomen and carmine vertex and neck. The brown forewings exhibit below the median a large white spot, another one behind it, parted by the lower median vein. The brown hindwing is white in the inner-marginal area; fringes white. Described from Mexico. *ruficeps*.

C. brunnea *Stretch* (26 f) has light olive-brown forewings with fine black veins; hindwings black with *brunnea*. a blue lustre. The body is black with a blue lustre; the two first palpal joints, the neck, shoulders, and stripes on the shoulder-covers are carmine. Hips, fringes and costal margin white. California.

- multifaria*. **C. multifaria** Wkr. (26 g) differs from the preceding by the entirely black forewings with a snow-white costal margin and fringes; the latter are blackish between the lower median and upper radial veins, on both wings. Head, shoulders, and proximal margin of the shoulder-covers scarlet, in f. **luteoscapus** Neum. and Dyar orange-yellow. California.
- rubroscapus*. **C. rubroscapus** Mén. (= *walsinghami* Hy. Edw.) (26 g) greatly resembles the preceding, but it has an entirely black costal margin and fringes; the latter are whitish only at the apices of the wings. — In *ochroscapus*. **ochroscapus** Grote & Rob. (= *corvina* Bsd.) the red parts of the anterior body are orange-yellow. Western United States.
- virginica*. **C. virginica** Charp. (= *latreilliana* Ky.) (26 g) is one of the largest species with dull blackish-brown forewings and somewhat darker, faintly lustrous blue hindwings; at the base of the forewing there is a metallic blue spot. Palpal base, vertex, neck, shoulders, and base of shoulder-covers orange; thorax and abdomen with a greenish-blue lustre. From the United States and Canada. — The larva being very densely haired black and white, on the dorsum yellow, shows white subdorsal and undulate lateral stripes; on the dorsum nine double hair-tufts. It lives on grasses.
- fosteri*. **C. fosteri** Rothsch. has an orange-yellow head, basal half of the collar, and inner side of the shoulder-covers. Thorax and abdomen are sooty blackish-brown, beneath sooty black. Forewings dark wooden brown, hindwings sooty black, both with white fringes. Length of forewings: 21 mm. Paraguay.
- conchylata*. **C. conchylata** spec. nov. (26 f). The body is blackish-brown, abdomen and hips with a blue lustre; the two first palpal joints, throat, hindhead and neck are carmine-rosy. The forewings are unicolorously dark brown, the hindwings in the marginal third with an irregular proximal bordering inclusive of the fringes purple red, the rest bluish-black. Described according to a ♀ from Peru (Vilcanoa). Type in the Coll. DRAUDT. According to the description, *Propyria nigrirufa* Rothsch., being unknown to me, must look like it.
- affinis*. **C. affinis** Druce. Anterior body olive-blackish with a bluish shine, the first 2 palpal joints, the neck and throat are orange, abdomen black with a blue lustre. Forewings olive black, fringes at the apex white, so is a triangular spot at the proximal angle. Hindwings black with a metallic blue lustre, ends of fringes white. Expanse of wings: 34 mm. Guatemala.
- clavia*. **C. clavia** Druce (26 g). The dark brown forewings exhibit a broad, yellowish-white longitudinal stripe from the base to the margin, the white hindwings a broad, brown border, being in the middle expanded like a spot, and proximal margin. Body metallic bluish-green with long black hair. Ecuador.
- albolineata*. **C. albolineata** Druce (= *projecta* Dogn.) looks like *clavia* (26 g). The body is black, on the thorax and abdomen with an intense metallic blue lustre. Forewings black; a white line extends from the base through the middle of the cell below the apex almost to the border; above its end there is a small, round, white spot; base and proximal margin are striped metallic blue. Hindwings black with a broad, white costal band not reaching the apex. Expanse of wings: 48 mm. North Peru.

154. Genus: **Dahana** Grote.

Siphon well-developed; palpi rather long porrect, the terminal joint turned somewhat downward. Antennae doubly combed. The ♂ shows at the base of the abdomen lateral tubercles with an aperture beneath. Wings long and narrow, both above the proximal angle somewhat concavely indented. The veins similar as in *Ctenucha*, but the upper radial vein, on the forewing, comes from the upper cell-angle; on the hindwing, both the lower radial veins come from the lower cell-angle, the subcostal vein at some distance before the upper cell-angle.

- atripennis*. **D. atripennis** Grote (26 g). Head and thorax blackish-brown with a metallic blue lustre. Palpal base, vertex, base of shoulder-covers, and upperside of the abdomen orange, the latter being spotted black beneath, laterally metallic blue. Forewings blackish-brown, dusted rusty brown, at the proximal angle an ochreous-yellow cuneiform spot. Hindwings black with a metallic blue lustre. Expanse of wings: 42 mm. Florida.
- cubana*. **D. cubana** Schaus. Head dark blue, beneath and laterally red, like the palpal base. Thorax black, shoulder-covers striped blue. Abdomen blue, the 2 last rings carmine, extending above almost to the base. Forewing black, at the base striped metallic blue. Hindwing metallic blue, apex and distal margin black. Expanse of wings: 28 mm. Cuba.

155. Genus: **Epectaptera** Hmps.

Palpi porrect, just projecting beyond the forehead. Forewing with a very much extended apex and a very oblique, somewhat concave distal margin, the veins being the usual ones; on the hindwing, the lower median vein rises far before the lower cell-angle, out of which the upper median vein and the lower radial proceed the middle radial vein rising from above the upper cell-angle, the uppermost radial vein and the subcostal from the upper cell-angle.

E. miniata *Rothsch.* (31 k). Head, thorax and abdomen are dark olive-brown, beneath lighter and *miniata*. more reddish, very long-haired. Forewing dark brown, at the costal margin carmine. In the cell there is a small, white, semidiaphanous spot, and a similar one on each side of the upper median vein. Hindwings vermilion with a black base, black veins, discal spot and margin. Length of forewings: 19 mm. Peru.

E. discalis *Schs.* (31 k). Body black, abdomen above suffused with metallic blue. Forewings brownish- *discalis*. black with interspersed, reddish buff scales; in the middle of the cell there is a square, whitish spot, behind the cell a blackish shade. Hindwings orange-red with black margins. Expanse of wings: 31 mm. Peru (Carabaya).

E. discosticta *Hmps.* (26 g). Anterior body black, suffused with metallic bluish-green, abdomen black, *discosticta*. curled greenish-blue. The black forewing exhibits at the base below the median an orange-yellow stripe, behind the cell an orange-yellow spot. The hindwings are orange with a black proximal and distal margin. Venezuela.

E. metochria *Dogn.* (= *drucei* *Rothsch.*) (31 i). ♂ palpi, head, antennae, patagia, tegulae and thorax *metochria*. black, abdomen black with a blue lustre, venter and legs black, the latter with some bluish hairs. Forewings above blackish-brown, beneath black. Hindwings above and beneath black, in the cell, in the postdiscal and submedian folds ochreous-yellow, but the veins remain black. Fringes black. 35 mm. Colombia, at an altitude of 3200 m. — **roseipennis** *Rothsch.* (31 f) differs from *metochria* by numerous, reddish-yellow scales being inter- *roseipennis*. spersed on the forewings; the hindwings are dark brown, strewn with reddish buff, in the disc rosy-red. The species is besides somewhat larger. Length of forewings: 21 mm. Bogotá.

E. laudabilis *Druce* (26 h) differs from *discosticta* by the wings being more brownish, by the absence *laudabilis*. of the postdiscal spot, and the yellow basal spot being only short. Bolivia (Rio Songo).

E. umbrescens *Schs.* (31 k). Head and thorax dark brown; palpi black, at the base white. Abdomen *umbrescens*. above black, strewn with ochreous-yellow, underneath more light grey. Forehips isabel-yellowish. Forewings dark brown, at the cell-end an indistinct dark spot, the proximal margin almost black. Hindwings brown, strewn with yellow, preponderantly in the cell; distal margin blackish. Expanse of wings: 30 mm. Peru (Carabaya).

E. innotata *Dogn.* (31 i) has a black body and uniformly dark brown, long, narrow wings. The forewings *innotata*. are rather densely scaled, the hindwings semidiaphanous except the apex and anal angle. Expanse of wings: 25 mm. Loja.

156. Genus: **Philoros** *Wkr.*

Distinguished from *Ctenucha* by the upper radial of the forewing rising from the upper cell-angle and by the palpi being obliquely erect, the terminal joint being porrect.

Ph. laura *Hmps.* (26 h) has a red head and anal apex; moreover, the black body exhibits a deep *laura*. blue lustre, the underside being more or less white. The forewings are black with white fringes at the apex and proximal angle; the hindwings blue with broad, white fringes and a white spot at the apex and anal angle. Known from Bolivia. — **colombina** *subsp. nov.* (26 h) differs by its snow-white costal margin, white spots on *colombina*. the shoulders, white-striped shoulder-covers, a broad, white longitudinal stripe on the mesothorax and entirely white fringes; besides, the white apical spot of the hindwing is much smaller and the yellowish stripe at the proximal margin of the forewing is absent altogether. Described according to 2 ♂♂ from Colombia (Rio Negro and Sosomoco, East Cordilleras, 1200 m). Type in the Coll. SEITZ. Perhaps a good species.

Ph. nora *Druce* (31 l). Anterior body black, abdomen bluish-black. Forehead and front of the palpi *nora*. white, so are the border of the collar and the legs; neck red. Forewings black, costal margin white, the proximal margin bordered with yellow. Hindwings dark blue, bordered with a bright red from the apex up to the proximal margin. Expanse of wings: 40 mm. Peru.

Ph. rubriceps *Wkr.* (= *scepsiformis* *Hy. Edw.*) (26 h) is an extraordinarily common animal being *rubriceps*. most widely distributed from Mexico to Argentina. It has dark brown forewings and bluish-black hindwings, the abdomen being suffused with metallic blue, and scarlet palpi, throat and vertex, which are orange-yellow in the form: **opaca** *Bsd.* (26 i); in this form occurring in Argentina, Paraguay and South Brazil, the forewings *opaca*. are darker, the hindwings with a deeper blue lustre. — **griseatus** *Rothsch.* from Venezuela (Merida) is everywhere *griseatus*. unicolorously drab, except the carmine palpi, throat and vertex.

Ph. affinis *Rothsch.* (31 l) from Peru and Colombia has more greyish-brown forewings with black *affinis*. veins, the hindwings have no blue lustre at all. Very widely distributed; Brazil, Uruguay, Paraguay, Argentina and Peru.

Ph. neglectus *Bsd.* approximates *affinis*, being somewhat larger, with quite pale brown, sometimes *neglectus*. almost whitish forewings with blackish-brown veins. The hindwings are semidiaphanous. The spots on the palpi and head are orange. Expanse of wings: 36—40 mm. Known from Mexico, Brazil, Peru and Argentina.

obscuratus. **Ph. obscuratus** *Hmps.* Body and wings pale ochreous-yellow, strewn with brown, abdomen above more brown. The forewings exhibit in the lower cell-angle a black dot, behind it a faded, dark brown band which is broken in the shape of an acute angle behind the lower cell-angle, and before the apex a hazy, brown oblique spot. Hindwing towards the base diaphanous. Expanse of wings: 40 mm. Colombia.

perirroratus. **Ph. perirroratus** *Hmps.* Ochreous, densely strewn with blackish. Abdomen above almost entirely blackish. Forewings very densely and uniformly watered brown. Hindwings semi-diaphanous, at the border more densely dusted and clouded brownish-black. Expanse of wings: 46 mm. Bolivia.

157. Genus: **Hyaleucerea** *Btlr.*

It strikingly approximates *Eucereon* from which it chiefly differs only by the two uppermost subcostal veins rising freely from the cell. The wings are long and narrow, the costal margin towards the apex strongly bent with a rather sharp point.

vulnerata. **H. vulnerata** *Btlr.* (= myrrhine *Burm.*) (26 i). The body is black, the abdomen curled red; large spots on the collar and shoulder-covers are white. The forewings are brown with black markings, large hyaline spots in the disc and behind the cell, and a small white apical spot. The hindwings are hyaline with a black border. *boliviana.* Distributed from Mexico to Argentina. — **boliviana** *subsp. nov.* A number of specimens from the Rio Songo in Bolivia (FASSEL) invariably have the two last abdominal rings above coloured all red.

phaeosoma. **H. phaeosoma** *Hmps.* (= *minuta* *Rothsch.*) (31 l). Head and thorax olive-brown, mixed with blackish-brown; neck carmine; palpal base yellow-white. Abdomen blackish-brown with a blue lustre, beneath white. Forewings blackish-brown, on the veins and in the cell striped olive-yellow, also an antemedian costal spot is olive; at the cell-end, behind it and below it, hyaline spots; an undulate antemarginal line and an apical spot are olive. Hindwings hyaline with black veins and a broad bluish-black border. Expanse of wings: 30 mm. Paraguay.

luctuosa. **H. luctuosa** *Mschlr.* is brownish-black, suffused with a dull bluish-green, on the body with a somewhat brighter metallic blue and green; the abdomen exhibits besides lateral and sublateral rows of metallic green spots. Hindwing with a large, hyaline discal spot extending almost to the margin. Expanse of wings: 40 mm. Surinam.

morosa. **H. morosa** *Schs.* (31 k). Body dull greyish-black, abdomen towards the end deep bluish-black; hind-head and on each side a spot below the eye dark red. Forewings greyish-black, the veins, a stripe in the cell and one below it, a broad median shade from the cell to the proximal margin, and an antemarginal shade black; at the base of the proximal margin there is a small, dark blue spot. Hindwing bluish-black with a diaphanous stripe in and below the cell. Expanse of wings: 43 mm. Costa Rica.

erythrotela. **H. erythrotela** *Wkr.* (26 i). Black; neck and apex of abdomen carmine. Wings hyaline with a broad black border and a discal spot cohering with the distal margin. Honduras; Venezuela; Guiana; Pará.

chapmani. **H. chapmani** *Klages.* Body brownish-black; abdomen, beginning from the 4th ring, with lateral red spots. Wings hyaline, with broad, blackish-brown veins and margins and a large discal spot. Expanse of wings: 26 mm. Venezuela. The species is better placed to the genus *Pezaptera* (p. 113).

fusiformis. **H. fusiformis** *Wkr.* (= *trifasciata* *Btlr.*) (26 b). Black; vertex, collar and neck laterally spotted carmine; front of palpi, forehead, shoulders, chest, forehips, and femora spotted white; the abdomen on the ventral side with two rows of white spots. Forewings black, thinly scaled; hindwings hyaline with a black border. From French Guiana to the Amazon.

leucoprocta. **H. leucoprocta** *Dogn.* (26 b) is one of the largest species with a sooty black body, being very conspicuous by the 4 last abdominal rings being coloured yellowish-white above; besides, the abdomen shows a white lateral line. The wings are sooty black with deeper black veins, cellular and submedian folds. The entirely black hindwings show in the cell a lighter streak. French Guiana.

leucosticta. **H. leucosticta** *Druce* (31 l) is likewise black; the abdomen exhibits a white dorsal spot only on the last segment; vertex, pro- and metathorax spotted white; lateral stripes on the abdomen white. Forewings similar as in the preceding, but with distinct darkenings at the costal margin, near the proximal angle and at the apex. The hyaline hindwings are bordered with black. Venezuela, French Guiana.

lugubris. **H. lugubris** *Schaus* is quite unicolorously sooty black, on the forewings in the interspaces somewhat more thinly scaled, with darkenings at the proximal margin, costal margin and cell-end; hindwing semi-diaphanous in the disc. Colombia, French Guiana.

uniformis. **H. uniformis** *Rothsch.* (31 l) is monotonously sooty brown-grey, veins, hindwings and abdomen darker, more black. The hindwings are towards the base lighter, diaphanous. Length of forewings: 23 mm. South Brazil (Sa. Catharina).

H. costinotata Dogn. (31 l). This species, having been described by us on p. 181 as *Eucereum* and figured *costinotata* on t. 311, is better inserted here.

H. sororia Schaus (31 l) looks like the *Eucereon*-species of the *costulatum*-group. Body blackish; *sororia*. 2 spots in the neck, stripes on the shoulder-covers, and the last abdominal rings orange-yellow; sides of the forehead, the underside of the 3 first abdominal rings, and stripes on the legs white. Hindwings black, between the veins striped whitish, in some places spotted ochreous-yellow; behind the cell there is a large white spot; the apex and a large costal spot at the cell-end with shades from there to the proximal margin are blackish. Hindwings grey-brownish white, with black veins and margins. Length of forewings: 27 mm. Costa Rica.

H. gigantea Druce (26 c) has very long-extended, brown forewings with fine, blue-white, strigiform *gigantea*. markings and a large, brown-black costal-marginal spot before the middle. The bluish-white, semi-transparent hindwings have a brown-grey marginal area. The abdomen is orange-yellow, at the base and on the last segment blackish-brown. Distributed from Mexico to Brazil.

H. lemoulti Schs. (26 b as *lugubris*) is more correctly placed here; as to the description comp. p. 171 *lemoulti*. as *Eucereum*.

H. mundula Berg (31 l). This species having been described as *Halesidota* is unicolorously ochreous- *mundula*. yellowish white on the body and wings, the veins and the head somewhat more yellowish. Serrations of the antennae beneath black. Expanse of wings: 28 to 36 mm. Brazil, Paraguay, Argentina.

Additions and Corrections.

The supplementary volume I of HAMPSON's Cat. Lep. Phal. with many new descriptions having been in the meantime published and now arrived in Germany, necessitates numerous additions and supplements, as well as synonymous notes. Very remarkable are the shiftings of many species into other genera, by which it is proved how very difficult it is to define the genera deviating in so minute a way. Particularly the volume of tables published in April 1915, has enabled us to figure yet many species described according to single specimens quite a number also by valuable material received subsequently, and for which we are particularly indebted to Mr. A. H. FASSL.

Owing to the priority of the name: **Amata** F. before **Syntomis** O., the name of the family is changed into:

P. 33. Amatidae.

P. 38, line 22 from below, insert after *strigosus* Druce:

P. novercida Kaye is black-brown on the body, with sparsely intermixed grey hairs; ventral valve *novercida*. bordered with white. Forewings hyaline with black veins and margins, dusted black-brown at the costal margin, in the cell and at the proximal margin; on the hindwing, the cell and a marginal stripe below the inner-marginal vein are also dark. It looks like *noverca*, but the lower median vein rises from the lower cell-angle, as in *strigosus*. Expanse of wings: 28 mm. South Brazil (Castro, Paraná).

P. 38, line 20 from below, for *P. sericeus* Schrottky read:

P. polybioides Burm. (= *sericea* Schrottky). To the habitat add Argentina. Size up to 30 mm. The tabular reference in *polybia* (10 c, as *sericeus*) refers to the present species.

P. 38, line 26 from below:

P. polybia Kaye is to be eliminated with the description and to be placed as synonym after: *noverca* Schaus (P. 39, line 7 from above).

P. 39, line 26 from below, to *aurifera* add: (27 a).

P. 39, „ 19 „ „ , to *caurensis* the following species: *steinbachi* is to be added as synonymous and

P. 39, „ 11 „ „ , to be eliminated with the description.

P. 39, „ 4 „ „ , **melanogen** Dyar is a distinct species and has the priority before: *deceptans* Zerny (p. 40, line 6 from above) which thereby becomes synonymous.

P. 39, after *polistes* insert:

P. aracia Jones (27 a) has a yellow head with brown palpi and vertex; thorax marked yellow and black. *aracia*. Legs red-yellow, partly striped black with white forehips. The first abdominal ring is yellow with 2 black sub-dorsal streaks, the two following ones being red-yellow, the rest black with a leaden gloss; ventral valve golden yellow, bordered with white. Wings hyaline with brown veins and margins, at the costal margin brown down as far as the middle radial, at the cell-end and proximal margin dusted with a coppery colour. Hindwings hyaline with narrow black veins and margins. Expanse of wings: 28 mm. South Brazil (São Paulo).

P. 40, line 6 from above, *deceptans* is to be eliminated as synonymous.

P. 40, „ 10 „ „ , (*polybioides* Burm.) is to be eliminated.

P. 40, „ 15 „ „ , after *ichneumoncus* insert:

- fassli*. **P. fassli** *spec. nov.* (27 a) is larger and more robust than the form *crabronis* of the preceding species which it approaches very closely. It may at once be distinguished by the tibiae and tarsi being entirely yellow; the femora are velvety black, the hips yellow. Sides of the forehead silvery white, palpi quite black, very long-haired and beard-like. Collar and shoulder-covers are bordered with yellow; mesothorax and a transverse stripe on the metathorax, as well as a spot on the shoulder orange-yellow; the strangulated abdominal ring is posteriorly bordered with a light brown; the large, black ventral valve is laterally bordered with a silvery white, the abdomen otherwise purple-black. Antennae brown with a purple lustre, before the apex white-ringed. Wings as in *crabronis*. Expanse of wings: 38 to 40 mm. Described according to a number of fresh ♂♂ from the Rio Songo, Bolivia (FASSEL).
- gracilis*. P. 40, line 28 from below, *gracile* is to be eliminated as synonymous; subsp. **gracilis** Klages is the form from Panama with black antennae with yellow tips, whereas *angustulum* has a carmine antennal shaft.
P. 40, line 26 from below: *nigrifer* (not „nigriferum“) Dyar is a distinct species having the priority before: *perconstrictum* Zerny (p. 40, line 23 from below) which thus becomes synonymous.
P. 40, line 2 from below, to *meridionale* add: (27 a).
P. 41, „ 12 „ above, „ *nigriceps* „ : (27 a).
P. 41, „ 16 „ „ , after *nigriceps* insert:
- alica*. **S. alica** Jones (28 l). Head and thorax blackish-brown with single, interspersed hairs of a leaden colour. Forehead bordered with whitish. Legs striped yellowish; the blackish-brown abdomen, on the 4th and 5th rings, exhibits yellow bands; the ventral side is whitish. The hyaline wings have fine, blackish-brown veins and margins, the forewings exhibit red-brown stripes at the costal and proximal margins. Expanse of wings: 20 mm. South Brazil.
P. 41, line 17 from above, add after *simile*: (= *cosmosomoides* Roltsch.) as synonymous (see p. 124, line 18 from above).
P. 41, „ 18 from below, to *melapera* add: (27 a).
P. 41, „ 10 „ „ , „ *abdominale* „ : (27 a).
P. 42, „ 7 „ above, „ *metamela* „ : (27 a).
P. 42, „ 10 „ „ , add after *metamela*:
- linda*. **S. linda** Jones (27 b). Head and thorax are yellow, the latter striped black. The 3 first abdominal rings are red-yellow, the rest black, with yellow bands, on the ventral side all yellow and red-yellow. Wings hyaline with fine black veins and margins, the forewing with a reddish-brown costal margin and proximal margin. Expanse of wings: 26 mm. Brazil (São Paulo).
P. 42, line 23 from above, *S. nigricornis* is to be taken away and placed to the genus *Loxophlebia* (see p. 61—64).
P. 42, „ 19 „ below: to *meerkatzi* add (27 a).
P. 42, „ 17 „ „ , add:
- matta*. **S. matta** Jones (27 b). Head black with white sides of the forehead and a yellow hindhead. Palpi at the base black, the rest yellow; thorax yellow, striped black. The two first abdominal rings are yellow, striped black, the second at the base red-yellow, the others are black, curled yellow; venter yellow. The hyaline forewings with narrow black margins and veins are red-yellow at the costal margin and base of the proximal margin. Expanse of wings: 22 mm. Brazil (São Paulo).
P. 42, line 11 from below, add after *melissa*:
- semelina*. **S. semelina** Jones (27 b) differs from the preceding by its yellow abdomen with fine black dorsal and lateral stripes and the large black apical spot of the forewing. Expanse of wings: 26 mm. Brazil (Santos).
- melissina*. **S. melissina** Kaye extremely resembles *semelina*, being somewhat smaller and more orange-yellow on the thorax and abdomen, the latter with a black dorsal stripe and segmental indentations; the 3 first abdominal rings exhibit small black lateral stripes turned downward at the ends. Ventral valve yellow. The forewings also have a large black apical spot, the hindwings are yellow in the cell and at the base of the proximal margin. Expanse of wings: 24 mm. Santos.
P. 43, line 12 from above, to *vespoides* add: (27 a).
P. 43, „ 3 „ below, insert after *aliena*:
- obliqua*. **P. obliqua** Hmps. (27 c) deviates from the preceding by the chocolate-brown forewing with a narrow, oblique subapical band of white colour, being proximally dusted somewhat red-brown. Expanse of wings: 24 mm. Ecuador.
P. 44, line 6 from above, place instead of *Paramya*:

9. Genus: **Methysia** Btlr.

and insert after *intersecta* the species: **notabilis** Wkr. and **melanota** Hmps. (p. 137).

P. 44, line 16 from above, after *acnetus* insert:

M. bricenoi Rothsch. of Ichoria on p. 86 line 5 from above.

P. 44, line 9 from below, read (11 a) instead of (10 a).

P. 44, „ 5 „ „ , *leuce* is to be taken out and placed to *Dasysphinx*.

P. 45, „ 3 „ above, to *duronia* add: (27 a).

P. 45, „ 7 „ „ , *sandion* is to be placed to *Cosmosoma*.

P. 45, „ 10 „ „ , *garleppi* „ „ „ „ „ *Dasysphinx*.

P. 45, „ 16 „ „ , *H. watkinsi* Druce is to be eliminated.

P. 45, „ 31 „ „ , after *sahacon* insert:

H. modesta *spec. nov.* (27 b) greatly resembles the preceding, but it is much smaller. Body black, *modesta*. on the forehead, collar, metathorax and femora spotted dull blue with a leaden gloss; the blue spot on the forehead is above bordered by a light yellow spot in the shape of a horseshoe; abdomen laterally and sublaterally likewise spotted blue; the first abdominal ring exhibits subdorsal white, small spots, the 3 first rings being posteriorly bordered with a light yellow. On the ventral side the first 3 rings are all white, the penultimate ring exhibits sublateral orange spots. Wings faintly yellowish hyaline, veins, costal margin and proximal margin orange brownish; a very narrow apical spot of the forewing and inner-angular spot of the hindwing are black. Forehips and tarsi yellow-white, the latter at the extreme ends blackened. Expanse of wings: 33 mm. Described according to 1 pure ♀ from the Rio Songo, Bolivia (FASSEL).

H. ianthina *spec. nov.* (27 b) likewise greatly resembles the preceding, larger than *modesta*; from the *ianthina*. latter it differs by brilliant orange-yellow spots on the forehead and behind the eyes. Collar and shoulder-covers bordered with orange; of the same colour is a median stripe on the thorax. The spots on the abdomen are of a metallic ultramarine blue, a transverse band across the first ring, and the posterior margins of the 4 first segments orange, dorsally expanded to triangular dorsal spots. Venter and legs like in *modesta*, but the forehips blue. The wings of a deeper yellow. Expanse of wings: 38 mm. 1 ♀ from the Songo (FASSEL).

P. 45, line 26 from below, for *staminea* insert the name *albizonata* Dogn. *albizonata*.

P. 45, „ 18 „ „ , to *trizona* add: (27 h).

P. 45, „ 3 „ „ , insert after *leucostalaeta* Burm. as another synonym: *quinquepunctata* Heyl. of p. 75 line 25 from above.

P. 46, „ 4 „ „ , above, to *magnolimbata* add: (27 b).

P. 46, „ 9 „ „ „ , „ „ „ *rhodocera* „ : (27 c).

P. 46, „ 16 „ „ „ , *bombiformis* is to be placed to *Dasysphinx*.

P. 46, „ 25 „ „ „ , for *penates* which becomes *synonymous* insert the name: *nigripes* Heyl. *nigripes*.

P. 47, „ 23 „ „ „ , after *ustrina* add:

I. pertexta *spec. nov.* (29 b) entirely resembles *ustrina*, but the anterior body is entirely black; the *pertexta*. abdomen, only on the two first rings, exhibits minute, subdorsal and sublateral, yellow spots, above small blue dorsal spots. Expanse of wings: 50 mm. There is 1 ♂ before us from Sa. Catharina (Brazil) from the Coll. WERNICKE.

P. 48, line 9 from below, to *joda* add: (10 a, as *lucens*), the figure does not reproduce *C. lucens*. The following description: *basiferoides* Strand, p. 49 line 1 from above is to be added as a synonym to *joda*.

P. 48, line 1 from below, insert after *basifera*:

I. meridensis Schaus (27 d) of p. 54 line 5 from above (*Sarosa*).

P. 49, line 1 from above: *basiferoides* is to be eliminated as a synonym of *joda*.

P. 50, „ 28, 21 and 17 from below, the 3 species *capistrata*, *earminata* and *jamaicensis* are to be placed to the genus *Phoenicoprocta* (p. 57).

P. 51, line 15 from below, to *cineta* add: (27 c).

P. 52, „ 18 „ „ „ „ , *simulans* „: (27 c).

P. 52, „ 16 „ „ „ „ , after *simulans* insert:

A. vitristriga Druce of p. 93 line 26 from above (*Saurita*).

A. trinitatis Rothsch. (27 c) looks almost like a *Macrocneme*: head and thorax being blackish-brown, *trinitatis*. spotted green, the abdomen blackish-brown with metallic green dorsal and lateral stripes; the first ring beneath white, the others suffused with green. Wings dark brown, the forewing with a green dot at the base. Expanse of wings: 34 mm. Trinidad.

P. 52, line 1 from below, insert after *sesiiformis* to which *xanthotarsis* is to be placed as synonymous:

S. flavicostalis Rothsch. of p. 74 line 27 from above (*Cosmosoma*).

P. 53, line 1 from above, *xanthotarsis* is to be eliminated as a synonym of *sesiiformis*.

P. 53, „ 4 „ „ „ „ , to *epona* add (27 c). and after *epona* insert:

S. atritorna Dogn. (27 c) deviates from *epona* by the abdomen being of a brighter orange-red, the *atritorna*. head and thorax of the same colour, with blackish-brown spots, on the vertex spotted blue; the hindwings are not yellow, but white hyaline with large black anal-angular spots. Expanse of wings: 34 mm. Colombia.

P. 53, line 25, after *notata* insert:

S. annotata Dogn. (27 c) differs from the form *innotata* of the preceding species by blackish- *annotata*. brown shoulder-covers, entirely brown legs and smaller size; the 4 first abdominal rings are unicolorously yellow, the others blackish-brown with small blue spots. Expanse of wings: 42 mm. Colombia.

P. 53, line 16 from below, to *helotes* add: (27 c).

P. 53, „ 13 „ „ „ „ , *ozora* is to be placed to the genus *Dasysphinx*.

P. 53, „ 9 „ „ „ „ , to *lutibasis* add: (27 d).

P. 54, „ 1 „ „ „ „ „ , above, „ *mora* „ „ : (27 d). Insert after it:

S. ignicornis Hmps. (28 l). Body blackish-brown, on the vertex and abdomen spotted blue, the last *ignicornis*. rings entirely suffused with blue, on the collar and thorax yellow spots. Antennae fiery red; tarsi orange. The 1st abdominal ring shows a yellow dorsal spot, the 2nd at the base a narrow, yellow ring, the 3rd laterally and beneath a yellow-white band. Forewings yellow hyaline with narrow, blackish-brown margins; the subcostal veins and discal fold fiery red like the base of the inner-marginal vein. Expanse of wings: 38 mm. Peru.

P. 54, line 5 from above, *meridensis* is to be taken out and to be placed to the genus *Isanthrene*.

P. 54, „ 18 „ „ „ „ „ , after *muesseens* insert:

D. pilosa Rothsch. of p. 56 line 26 from above (Gymnelia) and add: (= watkinsi Druce) of p. 45 line 16 from above (Homoeocera).

D. leuce Maassen of p. 44 line 5 from below (Homoeocera).

semicineta.

D. semicineta Dogn. (27 d) greatly approximates *buckleyi*, somewhat smaller, the abdomen more metallic blue, on the 1st, 4th, 5th and 6th rings with subdorsal orange spots. The border of the forewing is only narrow black, without any apical nor inner-angular spots. Expanse of wings: 40 mm. Colombia.

D. buckleyi Druce of p. 56 line 15 from below (Gymnelia).

D. baroni Rothsch. „ „ 56 „ 20 „ above „

D. ozora Druce „ „ 53 „ 13 „ below (Sarosa).

P. 54, line 19 from above, to *volatilis* add: (27 c).

P. 54, „ 23 „ „ „ after *volatilis* insert:

D. ockendeni Rothsch. of p. 55 line 4 from below (Gymnelia).

D. tarsipuncta Schaus. „ „ 56 „ 1 „ above „
to which we add: (27 e).

D. torquata Druce of p. 56 line 16 from above (Gymnelia).

D. bombiformis Rothsch. „ „ 46 „ 16 „ „ (Homoeocera).

D. boettgeri Rothsch. „ „ 55 „ 11 „ below (Gymnelia).

D. garleppi Rothsch. „ „ 45 „ 10 „ above (Homoeocera).

D. herodes Druce „ „ 56 „ 4 „ below (Gymnelia).

P. 54, line 24 from above: for *Lasioteles* Hmps. (nec Beth. Baker) place *Scellilasia* Hmps.

P. 54, „ 4 „ below, add to the diagnose of the genus: distinguished from *Cosmosoma* merely by the border of the hindwing exhibiting an excision before the anal angle. For this reason, HAMPSON enumerates here a great number of species having hitherto been reckoned to *Cosmosoma*:

P. 55, line 2 from above, after *lyrcea* insert:

G. carabayana Rothsch. of p. 75 line 15 from above (Cosmosoma).

G. bricenoi Rothsch. „ „ 75 „ 10 „ „ „

G. metallica Rothsch. „ „ 74 „ 23 „ „ „

G. dubia Rothsch. „ „ 76 „ 21 „ „ „

G. zelosa Dogn. „ „ 78 „ 6 „ „ „

to which we must add: (27 e).

P. 55, line 10 from above, *plumosa* is to be eliminated as a synonym of *Cosm. doris*.

P. 55, „ 28 „ „ „ after *taos* insert:

pavo.

G. pavo Hmps. (27 e) resembles *taos* and differs by orange palpi and spot on the forehead, the ventral side being also orange-yellow, on the 3rd and 4th rings striped black. The wings are more distinctly yellow hyaline, towards the base orange. Expanse of wings: 46 mm. Peru.

G. beata Btlr. of p. 75 line 25 from below (Cosmosoma).

G. hampsoni Klages „ „ 75 „ 20 „ „ „
to which we add: (27 d).

G. nigricornis F. of p. 75 line 16 from below (Cosmosoma).

G. simillima Rothsch. „ „ 74 „ 18 „ above „

G. steinbachi Rothsch. „ „ 74 „ 21 „ „ „

G. gaza Schs. „ „ 74 „ 10 „ „ „

to which we add: (27 d).

G. eusebia Druce of p. 84 line 16 from above (Poecilosoma).

G. tarapotensis Druce „ „ 74 „ 14 „ „ (Cosmosoma).

G. villia Druce „ „ 75 „ 7 „ below „

G. vesparia Perty „ „ 81 „ 3 „ above „

G. stuarti Rothsch. „ „ 75 „ 2 „ below „

G. sephela Druce „ „ 75 „ 10 „ „ „

G. cincta Schs. „ „ 74 „ 6 „ above „

G. scita Wkr. „ „ 80 „ 2 „ below „

G. lycopolis Druce „ „ 73 „ 6 „ „ „

G. flavitarsis Wkr. „ „ 74 „ 17 „ „ „

G. baroni Rothsch. „ „ 74 „ 2 „ „ „

G. guapila Schs. „ „ 74 „ 5 „ „ „

to which we add: (27 e).

G. beatrix Druce of p. 74 line 10 from below (Cosmosoma).

G. salvini Btlr. „ „ 75 „ 4 „ above „

G. colona Schs. „ „ 77 „ 7 „ below „

to which we add: (27 c).

G. lucens Dogn. „ „ 75 „ 8 „ above „

to which we add: (27 d), eliminating: (10 a).

G. hyaloxantha Dogn. (27 d) differs from the preceding by the head and thorax being almost entirely *hyaloxantha*. blackish-brown, only the vertex and collar showing blue spots. The abdomen exhibits on the 1st ring lateral orange spots, from the 2nd to the 6th rings metallic blue bands. Forewings yellow hyaline, subcostally and at the base of the proximal margin with orange stripes, the black margins and apical spots are broader. Expanse of wings: 42 mm. Colombia.

G. nobilis Schs. of p. 74 line 1 from above (Cosmosoma).
to which we add: (27 e).

G. viridicingulata Rothsch. of p. 75 line 20 from above (Cosmosoma).

G. ichneumonoides Rothsch. ,, ,, 74 ,, 21 ,, below ,,

G. ethodaea Druce ,, ,, 80 ,, 17 ,, ,,

P. 55, line 11 from below, *boettgeri*, and line 4 from below, *ockendeni* are to be inserted in the genus *Dasysphinx* (p. 54) line 7 from below, *plagiata* in the genus *Chroslosoma* (p. 67).

P. 56, line 1 from above, *tarsipuncta* is to be placed to the genus *Dasysphinx*.

P. 56, ,, 12 ,, ,, , to *paranapanema* add: (27 e).

P. 56, the species *lorquata* as far as *buckleyi* inclusively, as well as *herodes* are to be placed to *Dasysphinx*, *flavicornis* to *Cosmosoma*.

P. 57, line 20 from below, to *flavipicta* add: (27 e).

P. 57, ,, 11 ,, ,, ,, *vacillans* add: According to a publication by DRAUDT, the breeder H. W. B. MOORE in Brit. Guiana has bred from a laying a very variable series, among which there were beside the nomenclatural form *metachrysea* Druce, *chrysorrhoea* Hmps., furthermore *Leucotmemis thoracica* Schs. and *L. albigutta* Schs.; consequently, the species mentioned last would be merely forms of *vacillans*!

P. 57, line 4 from below, for *incandescens* read: *punicea*.

P. 58, ,, 18 ,, above, after *sanguinea* insert:

P. carminata Hmps. of p. 50 line 21 from below (*Autochloris*) to which is to be added: (27 c).

P. biformata Gibbs (27 f) has a black head, the forehead and vertex being suffused with blue; thorax *biformata*. scarlet, with a black base of the collar and black shoulders; palpal base orange. Legs black, hips red. The black abdomen shows metallic blue dorsal and lateral stripes, and on the first ring red subdorsal streaks. Forewings hyaline with broad black margins and discal spots.

P. 58, line 18 from above, to *trinitatis* add: (27 f).

P. 58, ,, 22 ,, ,, ,, *lydia* add: The breeder having been mentioned in *vacillans* has bred from one and the same laying beside *lydia* also *thera* Druce and *J. demona* Druce which would consequently have to be considered to be forms of *lydia*!

P. 58, line 30 from above, after *lydia* insert:

P. jamaicensis Schs. of p. 50 line 17 from below (*Autochloris*), and add: (27 f).

P. capistrata F. of p. 50 line 28 from below (*Autochloris*), and add the synonyma: (= *thomae* Luc., *cubana* Druce), the latter is consequently to be eliminated as a species on p. 58 line 10 from below; in the ♂ the disc of the forewing is entirely hyaline except the spot in the middle, in the ♀ the extent of the dark median band varies very much.

P. 58, line 29 from below, to *chamboni* add: (27 g).

P. 58, ,, 10 ,, ,, ,, *cubana* as a synonym to *capistrata* must be eliminated.

P. 59, ,, 11 ,, above, add the synonym: *paranensis* Schrottky which must be eliminated on p. 69 line 14 from below. The figure 26 k is better than 12 m.

TP. 59, line 15 from below, to *caymanensis* add: (27 f).

P. 60, ,, 20 ,, above, after *costalis* insert:

Ph. plebecula Dogn. (27 f) of p. 77 line 10 from above (Cosmosoma).

P. 60, line 24 from above, after *gaudens* insert:

Ph. mathona Dogn. Head and thorax blackish-brown, spotted and striped orange; abdomen with *mathona*. orange lateral bands, being united above on the 2nd ring; anal tuft and venter orange, the last ring with a blue lustre. Forewing hyaline with black veins, margins and apical spot, subcostally and at the base of the proximal margin striped orange. Proximal margin of the hindwing yellow haired. Expanse of wings: 24 mm. Ecuador.

P. 60, line 4 from below, to *discaphora* add: (27 g).

P. 61, ,, 17 ,, above, ,, *lateralis* ,, : (27 f).

P. 61, ,, 21 ,, ,, , for *sandix* insert the name *haemapleura* Hmps.

P. 61, ,, 22 ,, below, to *bisigna* add: (27 f), and eliminate the concluding sentence from: „May be“ to the end.

P. 61, ,, 8 ,, ,, ,, *flavipicta* add: (27 f).

P. 62, ,, 12 ,, above, ,, *cinclata* ,, : (27 f).

P. 62, ,, 18 ,, ,, ,, *aurantiaca* ,, : (27 f).

P. 62, ,, 22 ,, ,, , after *aurantiaca* insert:

L. brasiliensis Rothsch. of p. 81 line 11 from above (Cosmosoma).

P. 62, line 22 from above, to *egregia* add: (27 g).

P. 62, ,, 24 ,, below, ,, *metamela* ,, : (27 g), and insert in the description: distinguished from *fininigra* by the colour being more brown, not black, the hips being brown, not spotted white as there.

P. 62, line 2 from below, *inconspicua* is to be taken out and placed to the genus *Mesothen*.

P. 63, ,, 6 ,, above, to *flavinigra* add: (27 g).

P. 63, ,, 25 ,, ,, ,, *geminata* ,, : (27 g).

P. 63, ,, 28 ,, ,, ,, *peralta* ,, : (27 g).

P. 63, ,, 17 ,, below, ,, *crusmalica* ,, : (27 g).

P. 63, ,, 12 ,, ,, , after *crusmalica* insert:

L. davisi Gibbs. (27 h). Head black with white dots behind the antennae, and the forehead bordered *davisi*. with white. Thorax red-yellow. Chest and legs black, the latter partly white. Abdomen black, on the 1st

ring with a small white dot. Wings hyaline with black veins and margins and an orange-yellow base. Expanse of wings: 22 mm. Brit. Honduras.

P. 63, line 7 and 3 from below, *semiflava* and *cosmosomoides* are to be placed to *Mesothen*.

P. 64, .. 13 from above, to *albicincta* add: (27 g).

P. 64, .. 18 .. , , *socorrensis* add: (27 g).

P. 64, .. 27 .. , for *parea* insert the name: *pheiodes* Dogn.

P. 64, .. 15 .. below, to *multieineta* add: (27 h).

P. 64, .. 12 .. , after *multieineta* insert:

L. nigricornis Rebel of p. 42 line 23 from above (*Sphecosoma*), and add: (27 h).

P. 65, line 5 from above, to *biscxualis* add: (27 h).

P. 65, .. 10 .. , , *temperata* .. : (27 h).

P. 65, .. 16 .. , , *albifrons* .. : (27 h).

P. 65, .. 20 .. , , *albilimbata* .. : (27 i).

P. 65, .. 25 .. , after *albilimbata* insert:

aurata. **M. aurata** Dogn. (27 i). Head black with a white forehead; thorax and abdomen orange-yellow, spotted black, the latter in its whole length dorsally, and sublaterally on the 4th, 5th and 7th rings. Wings hyaline with black veins and margins, and some yellow colouring at the base of the forewing and along the proximal margin of the hindwing, before it black. Expanse of wings: 22 mm. Colombia.

P. 65, line 26 from above, *doris* is to be placed to the genus *Cosmosoma*.

P. 65, .. 29 .. , to *flavicostata* add: (27 g).

P. 65, .. 23 .. below, .. *nomia* .. : (27 g).

P. 65, .. 20 .. , *mysia* is to be placed to the genus *Chrostosoma*.

P. 65, .. 14 .. , after *rogenhoferi* insert as a distinct species:

M. perflava Kaye (27 i).

P. 65, line 11 from below, to *ockendeni* add: (27 f).

P. 65, .. 3 .. , , *aurantiaca* .. : (27 h).

P. 66, .. 19 .. above, after *ethela* insert:

M. semiflava Rothsch. of p. 63 line 7 from below (*Loxophlebia*).

M. cosmosomoides Rothsch. .. , 63 .. 3 .. , , ,

M. meridensis Rothsch. .. , 74 .. 24 .. , , (Cosmosoma).

M. inconspicua Kaye .. , 62 .. 2 .. , , (Loxophlebia).

pyrrhina. **M. pyrrhina** Jones (27 h) differs from *pyrrha* by the collar being bordered with white, the white base of the tarsi, and the black abdomen being subdorsally striped grey, with a white dot on the 1st ring. The ♀, on the forewings, is strewn with black in and behind the cell, and striped black in the cell-spaces. Expanse of wings: 22 to 24 mm. Brazil.

P. 66, line 20 from above, to *montana* add: (27 h).

P. 66, .. 24 .. below, .. *roseifemur* .. : it may perhaps be merely a form of *eaeruleicorpus*; in this species the extent of the red colour on the legs is apparently most variable.

P. 66, line 7 from below: after *catherina* insert:

aurantegula. **M. aurantegula** Jones (27 h) is blackish-brown on the body with an orange-spotted collar; terminal joints of palpi and tips of antennae white. Wings hyaline with black veins and margins. Expanse of wings: 28 mm. Brazil (Santos).

P. 66, line 7 from below, to *nana* add: (27 k).

P. 66, .. 4 .. , , *endoleuca* .. : (27 i).

P. 67, .. 10 .. above, after *pampa* insert:

M. abdominalis Rothsch. (27 i) of p. 162 line 17 from below (as *Agyrta*!).

P. 67, line 10 from above, to *pulchella* add: (27 i).

P. 67, .. 27 .. below, for *haematica* insert the name:

Ch. fenestrina Btlr., *haematica* and *zantes* are to be eliminated, there only remains the synonym *chalconitis*.

P. 67, line 11 from below, *fumosum* is to be taken out and placed to *Saurita*.

P. 68, .. 1 .. above, *Ch. anthracina* is to be eliminated and to be quoted as *saurita laeteipars* Dogn.

P. 68, .. 9 .. , *mosca* is to be taken out and placed to *Saurita*.

P. 68, .. 20 .. , to *trimaenulatum* add: (27 i).

P. 68, .. 18 .. below, .. *pellueidum* .. : (27 k).

P. 68, .. 16 .. , after *pellueidum* insert:

Ch. mysia Druce (27 k) of p. 65 line 20 from below (*Mesothen*).

Ch. plagiata Rothsch. .. , 55 .. 7 .. , (Gymnelia).

P. 68, line 15 from below, *sitiona* is to be taken out and placed to *Cosmosoma*.

P. 68, .. 13 .. , to *patricium* add: (27 i).

P. 68, .. 3 .. , after *tricolor* insert:

Ch. rica Dogn. (27 k) of p. 73 line 16 from below (*Cosmosoma*).

P. 68, line 3 from below, *marathum* Druce is to be eliminated as the synonym to *Saurita* *nox*.

P. 69, .. 14 .. , *paranensis* is to be eliminated as the synonym to *Phoeniceoproeta* *teda*.

P. 69, .. 6 .. , after *tenthredoides* insert:

L. lemoulti Rothsch. of p. 81, line '22 from above (*Cosmosoma*).

P. 70, line 10 from above, take *bella* out and place it to *Cosmosoma*.

„ 70, „ 14 „ „ , to *endochrysa* add: (27 k).

„ 70, „ 23 „ below, *felderi* is a smaller form of *emergens* and no separate species.

„ 70, „ 20 „ „ , to *albigutta* add: (27 k); according to Dyar, it is, like the following, identical with *Phoenico-*
procta vacillans!

„ 70, line 17 from below, to *thoracica* add: (27 k).

„ 70, „ 8 „ „ , according to HAMPSON'S opinion, *hoffmannsi* Rothsch. (p. 108, line 9 from below) having been described as *Catonotus* would have to be placed here as *Leucotmemis*; I adhere to my opinion that *Methysia chry-*
sonola is the same animal.

P. 71, line 27 from above, to *exomelan* add the synonym: *pyrsonola* Hmps.

„ 71, „ 14 „ below, „ *rubritarse* add: (27 k).

„ 71, „ 5 „ „ „ , *myrodora* „ : (27 k).

„ 71, „ 2 „ „ „ , read: (13 c), instead of (13 e).

„ 72, „ 16 „ above, *rubrobasale* is only a form of *sectinota*.

„ 72, „ 18 „ „ , to *enlella* add: (27 k).

„ 72, „ 20 „ below, „ *brasilicola* „ : (27 i).

„ 72, „ 16 „ „ , before *galatea* insert:

C. basistiba Dogn. (27 l). Anterior body blackish-brown, on the shoulders, metathorax, forehips *basistiba*.

and posterior chest spotted blue; the first 4 abdominal rings are orange-yellow with a black spot on the first ring, the rest blackish-brown, spotted blue. Forewings hyaline with black veins, margins, median and apical spots; at the base of the forewing there is a blue dot. Expanse of wings: 42 mm. Colombia.

P. 72, line 16 from below, to *galatea* add: (27 l).

„ 72, „ 3 „ „ , after *semifulva* insert:

C. sitiona Schs. (27 l) of p. 68 line 15 from below (*Chrostosoma*).

C. albifrons Dogn. (27 l). Body orange, with black antennae, palpi, legs except the base of the femora *albifrons*.

and apex of abdomen; forehead white. Wings hyaline with black margins and apical spots and some orange at the base. Expanse of wings: 30 mm. Panama.

P. 73, line 4 from above, *C. rubriguthum* is to be placed as an insignificant aberration to *teuthras* (p. 79 line 12 from above).

„ 73, line 16 from below, after *melathoracica* insert:

C. flavicornis Druce of p. 56, line 10 from below (*Gymnelia*!).

P. 73, line 16 from below, place *rica* to *Chrostosoma*, and line 13 and 10: *stryma* and *gracula* to *Saurila*.

„ 73, „ 6 „ „ „ , as far as p. 74, line 23 from above, *lycopolis* — *metallicum* are to be placed to *Gymnelia*; line 27: *flavicostale* to *Sarosa*; line 32: *meridense* to *Mesothen*; the following species from *ichneumonoides* to *stuarti* (p. 75, line 2 from below), as well as p. 76, line 21 from above, *dubium* all to *Gymnelia*.

P. 76, line 26 from above, to *mathani* add: (27 l).

„ 77, „ 1 „ „ „ , before *cinclutum* insert:

C. bella Kaye (27 m) of p. 70 line 10 from above (*Leucotmemis*).

P. 77, line 1 from above, to *cinclutum* add: (27 l).

„ 77, „ 10 „ „ „ , take out *plebecula* and place it to *Phcia*.

„ 77, „ 15 „ „ „ , to *corvicum* add: (27 i).

„ 77, „ 8 „ below, „ *phoenicophorum* add: From East Colombia (Villavicencio) there is from the Coll. FASSL a unicolorously blackish-brown example before me without any red on its body and wings: I denominate the form: *noctifera* (28 a).

P. 77, line 7 from below, place *colona* to *Gymnelia*.

„ 78, „ 10 „ „ „ , after *xanthostictum* insert:

C. sandion Druce (27 l) of p. 45 line 7 from above (*Homoeocera*).

P. 78, line 11 from above, in *durca* the name *nigripes* Heyl. is to be eliminated: after *durca* insert:

C. rasera Jones (27 l) differs from *durca* by the first three abdominal rings being beneath banded white; *rasera*.

the 1st ring exhibits also sublateral blue spots; the tarsi are black. On the under surface each wing is spotted blue at the base of the costal margin. Expanse of wings: 30 to 36 mm. Brazil (Santos; Castro Paraná).

P. 78, line 18 from above, to *pellucidum* add: (27 l).

„ 78, „ 23 „ below, after *crathidinum* insert:

C. rubricarpus Kaye (27 l) of p. 85 line 23 from above (*Mystrocneme*).

C. flavicinctata Dogn. (27 l) of p. 85 line 9 from above (*Mystrocneme*).

P. 78, line 6 from below, *zelosa* is to be placed to *Gymnelia* (not figured).

„ 78, „ 6 „ „ „ , eliminate the reference (14 b) together with the description and place it as a form to *festivum* by the name of: *auranticineta* form. nov. (= subsp. 1 Hmps.).

P. 79, line 3 from above, to *thoracica* add: (27 m).

„ 79, „ 7 „ „ „ , *sicula* is to be eliminated and to be placed as a synonym to *remotum* Wkr. (p. 80 line 25 from above).

P. 79, line 15 from below, the name: *tyrrhene* Hbn. with the synonym: *perfenestratum* Dyar (of p. 80 line 6 from above) is to be introduced for a form with an orange-red discal spot and a red-dusted marginal band.

P. 79, line 4 from below, to *achemonides* add: (27 m).

„ 80, „ 6 „ above, eliminate *perfenestratum*.

„ 80, „ 18 „ „ „ , to *anoxanthium* add: (27 m).

„ 80, „ 25 „ „ „ „ , *remotum* add *sicula* Dyar as synonymous.

„ 80, „ 17 „ below, place *ethodaea* to *Gymnelia*.

„ 80, „ 2 „ „ „ „ , *scita*, and p. 81 line 3 from above: *vesparia* to *Gymnelia*.

„ 81, „ 11 „ above, „ *brasiliense* to *Lorophlebia*.

„ 81, „ 22 „ „ „ „ , *lemoulti* to *Leucotmemis*.

„ 81, „ 25 „ below, to *galbanum* add: (27 m).

„ 81, „ 15 „ „ „ „ , *dorsicinctum* add: (27 m).

„ 82, „ 1 „ above, for *regestum* insert the name:

notostiba. **C. notostiba** Hmps. (notosticta Dogn. 1913 nec Dogn. 1909).

P. 82, line 9 from above, replace *carsors* by:

stictinola. **C. stictinota** Dogn.

P. 82, line 16 from above, to *notosticta* add: (27 m).

„ 82, „ 20 „ „ , after *notosticta* insert:

C. doris Druce of p. 65 line 26 from above (as *Mesothen*) and add as synonym: (= *plumosa* Rothsch.) of p. 55 line 10 from above (as *Gymnelia*).

diplosticta. **C. diplosticta** Dogn. (27 m) is very easily recognizable by the orange-yellow body being spotted black subdorsally, laterally, and sublaterally. Expanse of wings: 36 mm. Colombia.

P. 82, line 4 from below, to *thia* add: (27 m).

„ 83, „ 1 „ above, to *pseudothia* add the synonym: *thiacia* Hmps., and besides: (27 k).

„ 83, „ 5 „ „ , to *angustimargo* add: (27 m).

„ 83, „ 12 „ „ , the name: *intensa* Rothsch. is to be re-inserted, since *intensa* Wkr. is to be placed to *Saurita*.

„ 83, „ 15 „ „ , to *flavita* add: (27 m).

„ 83, „ 25 „ „ , „ *pytna* add: (27 m).

„ 83, „ 4 „ below, place *intensum* to *Saurita*.

„ 84, „ 1 „ above, place *ladan* to *Saurita*.

„ 84, „ 13 „ „ , to *P. chrysis* add:

From Villavicencio (East Colombia) there is a form before me from the Coll. FASSL, in which the red *flava*. colour of the thorax and of the 1st abdominal ring is golden yellow; I denominate it: **flava form. nov.** — In another form from the same origin the 4 first abdominal rings are scarlet, on which the small blue-opalescent *semirubra*. dorsal spots without any black bordering are very peculiarly prominent; it may have the name: **semirubra form nov.** (28 d).

P. 84, line 16 from above, place *eusebia* to *Gymnelia*.

„ 84, „ 25 „ „ , to *mapirensis* add: (28 a).

„ 84, „ 29 „ „ , „ *misionum* „ : (28 a).

„ 84, „ 12 „ below, HAMPSON has of late placed *vespoides* to *Cosmosoma*; I do not see the reason why, since in quite a number of specimens before me, the upper radial vein of the forewing always rises far below the upper cell-angle. After it insert:

annulatum. **P. annulatum spec. nov.** (28 h) resembles the preceding. The palpi are quite yellow; the base of the collar, 4 spots on the thorax, minute spots on the shoulders, and the apices of the shoulder-covers are black. Each abdominal ring is above curled black, beneath only beginning from the 4th ring. Wings like in *vespoides*. Described according to 1 ♂ from the Rio Songo (FASSL).

P. 85, line 9 from above, place *flavicinctata* to *Cosmosoma*.

„ 85, „ 14 „ „ , to *sectum* add: (28 a).

„ 85, „ 18 „ „ , „ *albicarpus* „ (28 a).

„ 85, „ 23 „ „ , place *rubricarpus* to *Cosmosoma*.

„ 86, „ 5 „ „ , „ *bricnoi* to *Melhyia*.

„ 86, „ 16 „ below, to *semiopaca* add: (28 a).

„ 86, „ 12 „ „ , „ *chrostosomides* add: (28 b).

„ 86, „ 4 „ „ , after *chalcomedusa* insert:

virescens. **I. virescens** Dogn. (28 a) is on the anterior body entirely blackish brown, with white-spotted anterior and posterior hips. Abdomen bronze-green like the forewings. Hindwings hyaline broadly bordered with a blackish brown. Ventral valve spotted white. Expanse of wings: 38 mm. Colombia, Bolivia.

P. 87, line 11 from above, *ochreiventris* is to be placed to *Saurita*.

trigutta. „ 87, „ 21 „ „ , eliminate the name *melanthus*, the species must be called: **trigutta** Wkr. After it insert:

melanthus. **P. melanthus** Cr. differs from the preceding by its black colour, red hindhead and collar. Underneath the 4 first abdominal rings are white. Hindwing with a broad, faded, blackish median band; hindwing in the basal half hyaline with black veins, distally quite black. Expanse of wings: 28 mm. Trinidad; Surinam.

P. 87, line 24 from above, to *nigrozona* add: (28 a).

„ 87, „ 17 „ below, eliminate *trabea* and place it as synonym to *picta* (line 15 from above).

„ 87, „ 1 „ „ , after *vesla* insert:

H. cardinalis Rothsch. of p. 91 line 3 from below (as *Saurita*).

P. 88, line 1 from above, to *gentilicia* add: (28 b).

„ 88, „ 9 „ „ , in *endoleuca* replace: (15 b) by (28 b). The species has a white inner-marginal area of the hindwing.

P. 88, line 14 from above, to *melita* add: (28 b).

„ 88, „ 16 „ „ , after *melita* insert:

eurytorna. **H. eurytorna** Hmps. (15 b as *endoleuca*) is distinguished by the inner-marginal area of the hindwing being in the ♂ expanded and beneath roughly scaled; it otherwise greatly resembles *endoleuca*. Expanse of wings: 36 mm. West Colombia.

P. 88, line 16 from below, to *melaleuca* add the description of the ♂: palpi anteriorly white; collar scarlet; mesothorax and the 5 first abdominal rings above and laterally red, the 2nd and 3rd rings are above white, the 5th spotted black; the hyaline part below and behind the cell of the hindwing is absent. Flies also in French Guiana.

P. 88, line 8 from below, for *sanguinea* Jones which becomes synonymous, place: *haemasoma* Curtis (28 b).
 „ 89, „ 1 „ above, before *vittata* insert:

P. flavicans Dogn. with the reference: (15 d as *semiflava*), (of p. 90 line 10 from below), as *Rhynchopyga*; the latter name becomes synonymous. The yellow colour is of a deeper orange-yellow in fresh specimens. *flavicans* was described as *Horama* on p. 143 line 12 from below and is to be eliminated there.

P. 89, line 29 from above, to *pentheri* add: (28 b).

„ 89, „ 11 „ below, *hymenopteridia* is to be placed as *Rhynchopyga* to the beginning of the following genus; for (15 c) read: (15 e).

P. 90, line 8 from above, to *semirufa* add: (28 b).

„ 90, „ 27 „ „ „ *braconida* „ (28 b).

„ 90, „ 10 „ below, after *subflamma* insert:

R. aurantiaca spec. nov. (28 b) differs very much from the other species. Forewing brown with darker *aurantiaca*. veins, cellular and submedian fold, and a slight brightening in the middle of the cell, being somewhat more distinct behind the cell, extending between the upper median and lowest radial as far as to the margin; at the apex there are also 3 or 4 small light spots. Hindwing orange-yellow, bordered with black, rather broadly at the apex. Body unicolorously blackish-brown, at the sides of the chest and of the 1st abdominal ring small, indistinct, orange-yellow spots. Expanse of wings: 35 mm. According to 2 ♀♀ 1 ♂ from the Songo, Bolivia (FASSL).

R. elongata Dogn. of p. 186, line 4 from below, (as *Correbia*). After the description insert: In Bolivia and Peru there flies a form: **bifasciata** form. nov. (= subsp. 1 *Hmps.*) (28 c) with a broad, ochreous *bifasciata*. yellowish antemedian band traversed by the dark veins, and a purely yellow postmedian transverse band; the white abdominal spots are bordered with black.

R. bicolor Dogn. (28 b) of p. 92, line 12 from above, (as *Saurita*).

P. 90, line 10 from below, eliminate *semiflava*.

„ 91, „ 3 „ above, to *steniptera* add: (28 d).

„ 91, „ 3 „ below, place *cardinatis* to *Holophaca*.

„ 92, „ 1 „ „ „ to *meerida*: HAMPSON considers *duccicordis* to be a distinct species and places it to *Rhynchopyga*; I received great numbers of this animal from Mexico, it is certainly a *Saurita* and, according to DYAR's personal assertion synonymous with *meerida*.

P. 92, line 8 from above, to *improvisa* add: (28 c).

„ 92, „ 12 „ „ „ place *bicolor* to *Rhynchopyga*.

„ 92, „ 16 „ „ „ to *tricolor* add: (28 c).

„ 92, „ 19 „ „ „ eliminate *hamon* which is a *Lithosida*.

„ 92, „ 10 „ below, to *talens* add: (28 c).

„ 92, „ 7 „ „ „ *submacula* „ (28 c).

„ 92, „ 3 „ „ „ *hemiphaea* „ (28 c) and as synonym: *pipio* Oberth.

„ 93, „ 1 „ above, „ *rubripuncta* „ (28 c).

„ 93, „ 6 „ „ „ for *mediorubra* insert the name: *S. haematica* Perty (= zantes *H.-Schäff.*, *mediorubra* Kaye).

„ 93, „ 9 „ „ „ to *anthracina* add: (28 d).

„ 93, „ 16 „ „ „ after *cassandra* insert:

S. coccinea spec. nov. (28 d) is smaller than the preceding and coloured on the wings just like it, *coccinea*. though a little lighter; at the base of the forewing there is a small red spot. The whole body above and beneath inclusive of the palpi and legs is scarlet, the latter being brownish at the tibiae; on the collar and abdominal sides there are large, metallic greenish-blue spots in a black ground; the anterior margin of the 2nd abdominal ring exhibits a black transverse band. Expanse of wings: 29 mm. According to 1 couple from the Songo, Bolivia (coll. FASSL).

P. 93, line 26 from above, place *vitistriga* to *Autochtoris*.

„ 93, „ 12 „ below, to *nox* add as synonym: (= *maratha* Druce) of p. 68 line 3 from below (as *Chrostosoma*).

„ 93, „ 7 „ „ „ *perspicua* add: (28 e).

„ 93, „ 4 „ „ „ after *perspicua* insert: *S. gracula* Dogn. (28 c) of p. 73 line 10 from below.

„ 93, „ 1 „ „ „ *phoenicosticta* insert:

S. fumosa Schs. (28 d) of p. 67 line 11 from below (*Chrostosoma*).

S. mosca Dogn. (28 d) of p. 68 line 9 from above (*Chrostosoma*).

P. 94, line 1 from above, to *clandestina* add: (28 d).

„ 94, „ 11 „ „ „ eliminate *venezuelensis* as a species and place it as a smaller form to *tmenus* (line 17 from below).

P. 94, line 19 from above, eliminate *thoracica* as a species and place it as a synonym to *conceisa* (line 14 from below).

„ 94, „ 22 „ below, after *vindonissa* insert:

S. cretheis Druce (28 d). Thorax and 1st abdominal ring above red, beneath blackish-brown; abdomen *cretheis*. bluish-black with lateral rows of metallic blue dots. The blackish-brown forewings exhibit in the cell-end and below it small hyaline stripes, as well as small spots between the veins rising from the cell; the hindwing likewise shows hyaline stripes in the middle. Expanse of wings: 26 mm. Ecuador.

S. hilda Druce (28 d) of p. 137 line 18 from above (*Methysia*).

P. 95, line 4 from above, to *metanifera* add: collar, shoulder-covers and metathorax are bordered with grey. On the forewing all the subcostal veins rise from one stalk.

P. 95, line 6 from above, add to *tiputina* the synonym: (= *obscura* *Ktages*), and eliminate this name inclusive of the rest of the sentence from „being“ to the word „*Ktages*“ on p. 94 line 15 from above.

P. 95, line 15 from above, to *lasiphtebia* add as synonymous: *culicina Oberth.*

„ 95, „ 15 „ „ , after *pectucida* insert:

S. ladan Druce of p. 84 line 1 from above (*Cosmosoma*).

S. ochreiventris Druce (28 e) of p. 87 line 11 from above (*Pseudomya*).

S. intensa Wlkr. of p. 83 line 4 from below (*Cosmosoma*).

S. stryama Druce of p. 73 line 13 from below (*Cosmosoma*).

S. lacteipars Dogn. (= *anthracina Draudt*) (12 l, as *anthracina*) of p. 68 line 1 from above.

P. 95, line 18 from below, to *dubiosa* add: the appendant cell mentioned in the diagnose of the genus seems to be an abnormal, casual condition.

P. 96, line 8 from above, to *diminuta* add the synonym: *ockendeni Roths.* of p. 126 line 12 from below (*Agyrtha*).

„ 97, „ 12 „ „ , „ *tisamena* add: (28 d).

„ 97, „ 17 „ „ , „ *mincrea* „ (28 d).

„ 97, „ 7 „ below, „ *vulcanus* „ the synonym: *descintes Dyar*. After it insert:

plutonica. **E. plutonica** Hmps. (*vulcanus* Druce part.) is most similar to the preceding, distinguishable by its red forehips and white lateral spots on the anterior half of the abdomen, all the rest being alike; it is doubtful whether it is a distinct species. Expanse of wings: 60 mm. Mexico.

P. 98, line 28 from above, to *elegans* add: (28 e).

„ 98, „ 21 „ below, eliminate subsp. *boliviana*. Replace it by the name *laetifica Maassen* (= *strigiventris* subsp. 1 Hmps.) as a distinct species, and eliminate the synonym *laetifica* in the following species.

P. 99, line 1 from above, to *xanthosoma* add: (28 e).

„ 99, „ 10 „ „ , „ *tydia* „ (28 e).

„ 99, „ 13 „ „ , after *tydia* insert:

transacta. **D. transacta** Wkr. (28 e) resembles the preceding and is smaller, in the ground-colour more red-brown; the forewings are marked almost the same, but the small spots at the base and below the middle are hyaline, not yellow. Expanse of wings: 26 mm. Brazil.

P. 99, line 19 from above, to *xanthobasis* add: (28 e).

„ 100, „ 1 „ „ , „ *hampsoni* „ (28 e).

„ 100, „ 17 „ „ , „ *austera* „ (28 e).

„ 100, „ 28 „ „ , „ *angasi* add the synonym: *amphitrite Luc.*, and add to the description: thorax and abdomen are unicolorously greenish-black.

P. 100, line 5 from below, to *jucundissima* add: ground-colour more green than blue, all the white spots smaller, abdominal end scarlet, not carmine.

P. 102, line 10 from above, eliminate *monticola* as a species and place it as synonymous to *cephus*.

„ 102, „ 29 „ „ , to *faterina* add: (29 b).

„ 103, „ 17 „ „ , after *cyanca* insert:

aurifera. **M. aurifera** Hmps. (28 f) is very similar, on the anterior body spotted green, abdomen suffused with green, not blue; besides, the ventral side is spotted white. Wings like in the preceding, but in the basal part of the forewing there is an oblique, black longitudinal band bordered upwards by a golden colour, the hindwing exhibiting only one blue spot behind the lower cell-end. Expanse of wings: 40 mm. Peru.

P. 103, line 23 from below, to *cacrutscens* add: (28 f).

„ 103, „ 18 „ „ , „ *semiviridis* „ (28 f).

„ 103, „ 14 „ „ , „ *nigricornis* „ (28 f).

„ 104, „ 16 „ above, „ *maroniensis* „ (28 g).

„ 104, „ 18 „ below, eliminate *affinis* as synonymous with *chrysitis*.

„ 104, „ 9 „ „ , to *guyanensis* add: (28 f).

„ 104, „ 4 „ „ , „ *cyancscens* „ (28 f).

„ 105, „ 20 „ above, eliminate the synonym: *cyllarus*.

„ 105, „ 24 „ „ , *hampsoni* is a distinct species, add to it: (28 f).

„ 105, „ 27 „ „ , eliminate *caurensis* as synonymous with *vittata*.

„ 105, „ 18 „ below, after *vittata* insert:

M. ockendeni Roths. of p. 110, line 1 from above (*Poliopastea*).

P. 105, line 5 from below, after *nigritarsia* insert:

lamprosoma. **M. lamprosoma** Hmps. (28 f) is well recognizable by its entirely metallic silvery blue abdomen which is black beneath and exhibits in the ♂ 2 rows of white dots. Otherwise the species is very much like the preceding, though the wings are more suffused with blue and the shoulder-covers striped blue. Expanse of wings: 22 mm. Panama.

cyllarus. **M. cyllarus** Druce is not synonymous with *indistincta*; anterior body black with metallic blue spots, the shoulder-covers being striped blue; tips of antennae white. Abdomen suffused with a silvery blue, with blue dorsal and lateral stripes; wings as in *indistincta*, but the blue colour there is here more green.

P. 106, line 1 from above, to *sura* add: (28 f).

„ 106, „ 7 „ „ , „ *viridifusa* „ (28 g).

„ 106, „ 10 „ „ , after *viridifusa* insert:

56a. Genus: **Chrysocneme** gen. nov.

Not essentially different from *Macrocneme* in the veins and other structure, but on the hindwing a rudimentary costal vein rises close at the upper cell-angle, not reaching the costal margin. Tibiae and tarsi are only above covered with hair; the first abdominal ring shows large subdorsal hair-tufts.

Ch. mirabilis *sp. nov.* (28 g). This wonderful discovery of FASSL has a velvety black body with large, *mirabilis*. extremely bright metallic green spots on the forehead, hindhead, and sides of the collar; shoulder-covers and legs are striped the same; furthermore are green: a very large spot on the mesothorax, dorsal, lateral and sub-lateral spots on the abdomen, at the base of the wing and the large ventral valve, the posterior margin of which is haired black and white. A large median spot on the collar, the thoracic sides and the 2 hair-tufts on the first abdominal ring are scarlet. Posterior tarsi orange-yellow. Wings black, suffused with a peacock-blue. Expanse of wings: 42 mm. A splendid ♂ is before me from Pacho, Colombia.

P. 107, line 12 from above: eliminate *pinocha* as synonymous with *Eupyra psittacus*.

„ 107, „ 16 „ „ , to *aurata* add: (28 g).

„ 107, „ 23 „ „ , „ , *longipennis* add: (28 g) and the description: Body black, suffused with blue; antennae after the black base orange. Femora above red, tibiae and tarsi orange; metathorax laterally spotted red. Wings blackish-brown, the forewing in the basal half with a blue lustre. Expanse of wings: 44 mm. Cuba.

P. 108, line 7 from above, after *ignila* insert:

Ch. uniforis *sp. nov.* (28 h) entirely resembles the preceding and may be the same species, but it has *uniforis*. only one round hyaline spot in the cell-end; the colour is a much purer bluish-green, the body and bases of the wings without any copper lustre at all. 1 ♀ from Bogotá (FASSL).

P. 108, line 14 from above, to *eorax* add: (28 g).

„ 108, „ 14 „ below, „ *ehaleipleurus* add the habitat: Venezuela.

„ 109, „ 10 „ above, after *opalizans* insert:

C. chlorota *Dogn.* (28 h). Head and thorax black, spotted blue and with white dots on the forehead, *ehlorota*. palpi, collar, chest and hips; abdomen metallic silvery blue, beneath white, the first ring black, above and at the sides with white dots. Forewings black, towards the base suffused with blue, on the hindwings only below the cell. Expanse of wings: 36 mm. Colombia.

P. 109, line 26 from above, *ehryseis* is to be placed as synonymous; the species has to be denominated as: *dorata dorata*.

Dogn. (of p. 150 line 7 from above — as *Eupyra*).

P. 109, line 22 from below, to *plumulatus* add: (28 h).

„ 109, „ 13 „ „ , after *antennatus* insert:

58a. Genus: **Pseudophaeos** *Hmps.*

Distinguished from the preceding by the antennae being in the ♂ covered with hair in the basal halves above; on the forewing the upper median vein rises before the cell-angle, from which both the lower radial veins rise; only the uppermost subcostal vein rises separately from the cell, the 4 lower ones are on a common pedicle. On the hindwing the lower median vein rises before the cell-angle, from which the upper radial rises together with the lower radial; the middle radial vein is present and comes from above the lower cell-angle.

P. rosenbergi *Rothsch.* of p. 110 line 5 from above (*Poliopasta*).

P. 110, line 1 from above, place *oekendeni* to *Maerocneme*.

„ 110, „ 5 „ „ , „ , *rosenbergi* to *Pseudophaeos*.

„ 110, „ 10 „ „ , HAMPSON places *verdivittata* as doubtful to *Calonolos* after *tripunelatus*.

„ 111, „ 15 „ „ , after *haemorrhoidalis* insert:

M. pyroproctis *Hmps.* (29 b) is considerably larger than the preceding and differs by the red places *pyroproctis*. being here orange, only the 3, not 4, last abdominal rings exhibiting this colour. The black cell-spot of the forewing terminates rounded off close below the cell; otherwise very much alike. Expanse of wings: 62 mm. Peru.

P. 111, line 20 from above, after *paula* insert:

M. analis *Schs.* (28 h) of p. 114 line 27 from above (*Aethria*).

P. 112, line 1 from above, to *fulvicaudata* add: (29 b).

„ 112, „ 5 „ „ , eliminate *monstrabilis* and place it as synonymous to *latifascia f. ismenc* (line 23 from below).

„ 112, „ 18 „ „ , to *fumida* add: (28 h).

„ 113, „ 16 „ „ , place *frigida* to *Aethria*.

„ 113, „ 10 „ below, after *sordida* insert:

P. chapmani *Klages* (28 i) of p. 194 line 9 from below (*Hyaleucerea*).

P. 114, line 23 from above, eliminate *innotata* and place it as synonymous to the preceding species *carnicauda*.

„ 114, „ 27 „ „ , place *analis* to *Mesolasia*.

„ 115, „ 23 „ „ , to *leucaspis* add as synonymous: *langleyi* and eliminate this species on line 9 from below.

„ 115, „ 21 „ below, eliminate *eliza* and place it as synonymous to *daltha*: the ♂ under surface is not spotted white.

A. tenuistriga becomes a distinct species being very closely allied to *ocina*.

P. 116, line 3 from above, after *rubipictus* insert:

A. frigida *Burm.* of p. 113 line 16 from above (as *Trichura*).

P. 116, line 22 from below, eliminate the 68. genus: *Aethriopsis* together with *barbala* and description and place it as synonymous to *Diptilon philocles* p. 121 line 11 from above.

P. 117, line 5 from above, to *flavieineta* add: (28 i) and the synonym: *suapurensis* of p. 118 line 11 from below.

„ 117, „ 12 „ „ , after *vespina* insert:

nephelophora.

A. *nephelophora* Hmps. (28 i). Black; palpi, frontal sides, vertex, borders of the collar and of the shoulder-covers, as well as a spot on the metathorax orange-yellow; chest and legs yellow, the latter at the femoral-tibial angles black. Abdomen posteriorly with yellow ring-indentations, on the 1st ring with subdorsal yellow stripes, venter yellowish. The hyaline wings with yellow-brown veins and fine margins show brownish darkening below and behind the cell. Expanse of wings: 32 mm. Paraguay.

P. 117, line 22 from above, to *rubricauda* add: According to HAMPSON, the type of *quindensis* denoted by DOGNIN as a ♂ is nevertheless a ♀; in this case the latter species would have to be separated from *rubricauda*.

P. 117, line 26 from below, to *notha* add: (28 i).

.. 117, .. 21 .. , , , *auranticincta* .. (28 i).

.. 118, .. 26 .. , above, place *variegata* to *Abrochia*.

.. 118, .. 11 .. , below eliminate *suapurensis*.

.. 119, .. 24 .. , to *parcipuneta* add: (28 h).

.. 119, .. 21 .. , , , *restrita* .. (28 i).

.. 119, .. 15 .. , , , place *albipuncta* to *Napata*.

.. 119, .. 12 .. , , , to *elongata* add: (28 k).

.. 119, .. 8 .. , , , *ealita* .. (28 k).

.. 120, .. 7 .. , , , *espia* .. (28 g).

.. 120, .. 3 .. , , , *sylpha* .. (28 k).

.. 121, .. 11 .. , above, , *philocles* .. as synonymous: *barbata* Schrottky (p. 116 line 22 from below) as *Aethriopsis*.

.. 121, .. 24 .. , , , after *aterea* insert:

gladia.

D. *gladia* Jones (28 k) is on the body black, forehead whitish, middle and hind legs spotted yellow. Abdomen beneath on the 4 first segments and the last yellow. Anal tuft grey. Forewing like in the preceding, hindwing in the costal half yellow, below it black, the proximal margin hyaline with a black border. Expanse of wings: 24 mm. Brazil. São Paulo.

P. 121, line 21 from below, to *erassum* add: (28 i).

.. 122, .. 16 .. , , , eliminate *pseudopolybia*.

.. 122, .. 8 .. , , , to *affinis* add: (28 k).

.. 122, .. 5 .. , , , *nigricauda* .. (28 i).

.. 123, .. 7 .. , above, after *eumenes* insert:

baura.

E. *baura* Jones (28 i) is on the anterior body orange-yellow and black, the abdomen blackish-brown, the first ring dorsally, the 2 next ones subdorsally spotted yellow, on the underside the 3rd and 4th rings carmine like the middle and posterior tibiae. Wings hyaline with black veins and margins, the forewing subcostally, at the base of the proximal margin and on the transverse vein red; in the cell-end and behind it there is brown clouding. Expanse of wings: 32 mm. Brazil (São Paulo).

P. 123, line 18 from above, to *albipuncta* add: (28 i).

.. 123, .. 3 .. , below, , *azurea* add the synonym: *rubroanalis* Rothsch. of p. 163 line 4 from above (as *Agyrta*!), and: (28 l).

.. 124, line 19 from above, eliminate *cosmosomoides*.

.. 124, .. 25 .. , , , in *augusta* read: (26 k) instead of (19 h).

.. 124, .. 19 .. , below, after *sanguitarsia* insert:

A. *caurensis* Klages (28 l) of p. 126 line 13 from above (*Pseudargyrodes*).

A. *variegata* Kaye (28 l) of p. 118 line 28 from below (*Argyrodes*).

P. 124, line 7 from below, to *letrazona* add as synonymous: *pseudopolybia* Schrottky of p. 122 line 16 from below (*Eumeno-gaster*).

P. 125, line 1 from above, place *julumito* as a form to *sanguiceps* (line 6 from above).

.. 125, .. 15 .. , below, to *alridorsala* add: (28 l).

.. 126, .. 8 .. , above, after *moza* insert:

nivaca.

A. *nivaca* Jones (28 l). This small species described as *Heliura* (!) is very easily discernible by the yellow costal margin of the forewing with a broad brown median band, the body being carmine, only the head brown; the abdomen shows brown ring-indentations and a silvery blue stripe on the last rings; palpi and tarsi are orange, at the ends black. Expanse of wings: 26 mm. Brazil (Matto Grosso).

P. 126, line 8 from above, eliminate the genus: *Pseudargyrodes* together with the species *caurensis* (= *Abrochia sanguitarsia*).

P. 126, line 18 from below, after *hypoleucus* insert:

E. *rubrothorax* Rothsch. of p. 128 line 10 from above (*Teucer*).

To *E. obscuratus* add: (28 n).

P. 126, line 15 from below, after *obscuratus* insert:

E. *fuliginosa* Rothsch. (28 n) of p. 168 line 19 from below (*Heliura*).

P. 127, line 11 from above, after *homopteridea* insert:

C. *postflavida* Rothsch. (28 n) of p. 168 line 29 from above (*Heliura*).

C. *dolens* Schs. (28 n) of p. 168 line 25 from above (*Heliura*).

P. 127, line 26 from above, place *distincla*, and line 8 from below: *apicalis* to *Mesocerea*.

.. 127, .. 12 .. , below, place *germanus* as a form to *hypophaeus*.

.. 128, .. 6 .. , above, *obsoleta* is a distinct species. There are now before me 2 more specimens from FASSL from Muzo (Colombia). The species is at once discernible by its red forehips; in *glaucoptis* they are white.

P. 128, line 10 from above, after *earmania* insert:

rosada.

T. *rosada* Dogn. The body is dark red-brown, the abdomen posteriorly with a blue lustre. Forewings dark brown with a dark discal spot, the hindwing in the basal half carmine, at the border bluish-black, at the

apex very broad, towards the proximal angle narrower. In the form: **puelengei** Dogn. the hindwings are entirely *puelengei*. darkened, with a narrower marginal band. Expanse of wings: 30 mm. Ecuador.

P. 128, line 10 from above, place *rubrothorax* to *Ecdemus*.

„ 128, „ 12 „ „ „ „ *brunnea* to *Eucceon*.

„ 128, „ 14 „ below, eliminate *flavicornis* and place it as synonymous to *caeruleus* (line 5 from below).

„ 129, „ 25 „ above, to *capysca* add: (28 l).

„ 129, „ 11 „ below, „ *gnomoides* „ (28 l).

„ 129, „ 10 „ „ „ after *gnomoides* insert:

E. phlebitis Dogn. (28 k) differs from the two preceding by the neck being spotted orange, the collar *phlebitis*. and shoulders entirely unspotted, the abdomen beneath white almost to the end; the veins of the forewing are striped lighter grey, and the hindwing in the disc very extensively hyaline. Expanse of wings: 30 mm. Brit. Honduras.

P. 129, line 5 from below, to *vinasia* add: (28 k).

„ 130, „ 10 „ above, *dodaba* is to be placed as a form to *inornata* (line 6).

„ 130, „ 14 „ below, after *obsoleta* insert:

E. grisescens Hmps. (28 l) is unicolorously blackish-brown, tinted grey, on the vertex, shoulders and palpal base spotted yellow, ventral side white. Veins of the forewing lighter grey, behind the cell a faded whitish spot. Hindwing with a bluish-grey tint and a white stripe in and below the cell. Expanse of wings: 34 mm. Venezuela.

P. 130, line 6 from below, to *sixola* add: (28 k).

„ 131, „ 23 „ „ „ eliminate *giganteum* and place it instead of *hampsoni* p. 132 line 2 from above.

„ 131, „ 20 „ „ „ to *klagesi* add: (28 m, 1st figure).

„ 132, „ 5 „ above, „ *hoffmannsi* „ (28 m).

„ 133, „ 11 „ „ „ „ *phaeoptera* „ (28 k).

„ 133, „ 19 „ „ „ „ *ustulata* „ the preceding *rosenbergi* as an insignificant form. Add besides:

f. columbina Dyar is very conspicuous by an orange-yellow discal spot of the forewing and white *columbina*. forehips.

P. 134, line 1 from above, place *caurensis* as a form without any red spots of the neck to *bulleri* (p. 133 line 6 from below), as well as *musicola* of p. 135 line 20 from below as a form with a white-spotted forehead. — *caerulescens* *caerulescens* form. nov. (= ab. 1 Hmps.) is another form with blue instead of green colouring on the anterior body and forewings, only the abdomen being golden green.

P. 134, line 6 from above, to *cyanopasta* add: (28 k).

„ 134, „ 10 „ „ „ „ *painei* „ (28 m).

„ 134, „ 22 „ „ „ „ *scintillocollaris* „ (28 m).

„ 134, „ 25 „ „ „ insert after it: *albipunctata* Lathy of p. 133 line 25 from above (*Eriphioides*).

„ 134, „ 26 „ „ „ „ *phaiodes* add: (29 a). After it insert:

C. viridis Lathy (28 n) of p. 132 line 6 from below (as *Eriphioides*).

C. metallica Roths. (28 n) of p. 136 line 25 from below (*Antichloris*).

P. 134, line 15 from below, to *bricenoi* add: (28 m).

„ 135, „ 1 „ above, „ *chalcoviridis* „ (29 a).

„ 135, „ 9 „ „ „ „ *chloroptegia* add as synonymous: *nigrolineala* Roths. of p. 126 line 13 from below (*Antichloris*).

P. 135, line 14 from above, to *affinis* add: (28 n).

„ 135, „ 18 „ „ „ „ *viridisalurala* „ (28 m).

„ 135, „ 22 „ „ „ after *viridisalurala* insert:

C. scotoptera Hmps (28 n) (= *Amycles klagesi* Roths.) of p. 136 line 10 from above.

P. 135, line 22 from above, to *underwoodi* add: (28 m).

„ 135, „ 26 „ „ „ „ *simplex* „ (28 m).

„ 135, „ 22 „ below, „ *klagesi* „ (28 m, last figure). After it insert:

C. dolosa Wkr. of p. 136 line 7 from above (*Amycles*).

C. intensa Roths. (28 n) of p. 136 line 21 from below (*Antichloris*).

C. atrinervis Roths. (29 a) of p. 136 line 8 from below (*Antichloris*).

C. steinbachi Roths. (29 a) of p. 136 line 4 from below, as a distinct species.

P. 136, line 3 from above, to *tenebrosa* add: (29 a).

„ 136, „ 5 „ „ „ „ *brinkleyi* „ (29 a).

„ 136, „ 7 and 10 from above, place *dolosa* and *klagesi* to *Ceramidia*.

„ 136, „ 19 „ „ „ to *puriscal* add: (29 c).

„ 136, „ 21 „ below, place *intensa* to *Ceramidia*.

„ 136, „ 17 „ „ „ to *criphia* add as synonymous: *quartzii* of p. 137 line 3 from above.

„ 136, „ 13 „ „ „ eliminate *nigrolineala*.

„ 136, „ 8 „ „ „ place *alrinervis* to *Ceramidia*.

„ 137, „ 3 „ above, eliminate *quartzii*.

„ 137, „ 10 „ „ „ the genus *Methysia* is to be eliminated and replaced by:

96. Genus: **Ceramidiodes** -Hmps.

Very much like *Antichloris*, but on the forewing the ♂ shows a scent-scale stripe along the middle of the costal margin beneath and at the proximal margin long hair, the same at the costal margin of the hindwing which is very convex. In the veins of the forewing no other difference, but on the hindwing the lower radial vein is present and rises, together with the upper median vein, from the lower cell-angle.

C. mathani Roths. of p. 133 line 14 from below (*Ceramidia*).

P. 137, line 16 from below, eliminate *flavidorsia* as a synonym to *Lymire metamelas*.
 „ 137, „ 9 „ „ , after *opponens* insert:

P. popayana Dogn. of p. 180 line 13 from below (*Eucereon*).

P. 137, line 6 from below, to *major* add: (29 c).
 „ 137, „ 3 „ „ , „ *unimacula* „ (29 c). Insert after it:

P. pseudodelphyre Rothsch. of p. 136 line 26 from below (as *Agyrta*!) with the reference: (29 c).

P. 138, line 11 from below, HAMPSON did not state *remissa* as an *Amatide*.
 „ 138, „ 9 „ „ , eliminate *S. auranticauda* which is the Arctiid *Melaxanthia vespiformis*.
 „ 139, „ 15 „ above, to *atricincla* add: (29 c).
 „ 139, „ 18 „ „ , „ *flammans* „ (29 c).
 „ 139, „ 22 „ „ , after *flammans* insert:

N. ockendeni Rothsch. (29 c) of p. 188 line 5 from below (*Propyria*).

N. bipunctata Hmps. (*ockendeni* Rothsch.) (26 h) of p. 193 line 8 from above (*Epectaptera*).

N. nigrorufa Rothsch. (29 d) of p. 188 line 2 from below (*Propyria*).

alterata. **N. alterata** Wkr. (= choana Druce) (29 d) is a large, beautiful, black and orange-yellow species. The abdomen is white beneath. The forewing shows a large triangular spot in the basal half and an oblique subapical band, the hindwing 2 stripes at the proximal margin and a marginal spot in the middle. Expanse of wings: 44 mm. From Venezuela, Brazil, Ecuador and Peru.

cordigera. **N. cordigera** Warr. (29 c) is similar, but the body is quite blackish-brown, only the abdomen shows yellow lateral stripes and a white ventral side. On the forewing the triangular spot is absent, the hindwing exhibits a reniform spot. Expanse of wings: 36 mm. Venezuela.

P. 139, line 23 from above, to *alalanla* add: (28 n).
 The species is to be inserted after *terminalis* (p. 141 line 7 from above).
 P. 139, line 26 from above, to *hyporhoda* add: (29 d).
 „ 139, „ 24 „ below, „ *splendida* „ as synonymous: *melinda* Dyar of p. 152 line 18 (*Cyanopepla*).
 „ 139, „ 11 „ „ , eliminate the sentence: „Possibly — ???“.
 „ 139, „ 4 „ „ , in *maranhaonis* replace: (27 a) by (29 a).
 „ 140, „ 5 „ above, eliminate *abbreviata* together with the description: = *Ctenucha biformis* p. 190 line 17 from above.
 P. 140, line 23 from above, to *subflavescens* add: (29 c).
 „ 140, „ 27 „ „ , „ *metamela* „ (29 e).
 „ 140, „ 22 „ below, „ *cuckloa* „ (29 a).
 „ 141, „ 1 „ above, „ *pseudolelex* „ (29 f).
 „ 141, „ 16 „ „ , eliminate *venezuelensis* and place it as synonym to *leucoletus* (line 11 from above).
 „ 141, „ 25 „ „ , after *albimaculata* insert:

N. albipuncta Druce (29 e) of p. 119 line 15 from below (*Hypocladia*).

P. 141, line 15 from below, place *boettgeri* to *Delphyre*.
 „ 141, „ 11 „ „ , to *quadrinaculata* add as synonymous: *borealis* Rothsch. of p. 160 line 12 from below (as *Micraga*).
 P. 141, line 6 from below, to *sanguicincta* Hmps. add as synonymus: *conchyliata* Draudt (26 f) of p. 192 line 17 from above.
 P. 141, line 3 from below, to *flaviceps* add: (29 e).
 „ 142, „ 9 „ above, after *broadwayi* insert:

cortes. **N. cortes** Gibbs (29 e) greatly resembles the preceding, with somewhat larger white spots, and it is easily recognizable by the 3 last red abdominal rings; the ventral side of the abdomen is white in the basal half, behind it red. Expanse of wings: 44 mm. Brit. Honduras.

P. 142, line 24 from above, to *metamelas* add as synonym: *flavidorsia* Hmps. of p. 137 line 16 from below (*Pseudaclytia*).
 After it insert:

fulvicollis. **L. fulvicollis** Dogn. (29 d) has a quite blackish-brown body, only the neck is ringed orange, and the forehips are white. The wings are blackish-brown, too, the hindwing in the discal area hyaline. Expanse of wings: 26 mm. French Guiana.

P. 143, line 3 from above, after *lanceolata* insert:

L. nitens Rothsch. (29 e) of p. 154 line 8 from below (*Trichodesma*).

P. 143, line 12 from below, place *flavicans* to *Psitopleura*.
 „ 143, „ 2 „ „ , to *flavata* add: (29 g), and the following description: *fulvitaris* is to be placed to it as synonymous.
 P. 144, line 11 from below, to *affinis* add: (29 g), and as synonymous: *pugione* Oberth.
 „ 146, „ 14 „ above, to *imitans* „ (26 m).
 „ 146, „ 20 „ below, *pitthea* is only synonymous, not a subsp.
 „ 146, „ 10 „ „ , after *cocho* insert:

nephelophora. **P. nephelophora** Hmps. (29 f) (= *cocho* ab. 1 Hmps.) differs from the preceding by the collar and soulder-covers being spotted metallic blue. The forewings are more broadly bordered with black with a much larger discal spot and black dusting behind it. Expanse of wings: 38 mm. Brazil (São Paulo).

P. 146, line 10 from below, to *chimaera* add the synonym: (= *cocho* ab. 3 Hmps.)
 „ 147, „ 14 „ „ , after *corydon* insert:

megathyris. **Chl. megathyris** Hmps. (29 f). Body black with bluish-white dots, the abdomen beginning from the 3rd ring with lateral blue bands. Forewing black with metallic blue stripes near the base and 2 very large

hyaline spots; hindwings with a large hyaline spot in and below the cell and a double one behind it. Expanse of wings: 44 mm. Venezuela.

P. 147, line 5 from below, to *pyroproctis* add: (29 d).

„ 148, „ 4 „ above, before *schausi* insert:

I. trogon *sp. nov.* (29 e) greatly resembles in its exterior the preceding on the body and forewings, *trogon*. the hindwings, however, being like in *schausi*. Hips all white, the sublateral spots on the abdomen very large; instead of the one white spot on the hindhead there are 4 behind the eyes; also at the base of the wing there are two white spots. In the specimen which I designated as the type there is on the forewing, behind the cell above the middle radial, a small narrow hyaline spot, above it three more light diffuse patches. In the second specimen these spots are absent, the hindwings are much more extensively black, only one spot in the cell and one behind it are hyaline. The abdomen exhibits lateral hair-tufts at the base, like in *trogonoides*, whereas in *schausi* they are absent. Expanse of wings: 41 mm. Upper Rio Negro in East Colombia (FASSEL).

P. 148, line 4 from above, to *schausi* add: (22 b).

„ 148, „ 23 „ „ „ „ *stellans* add for the ♂: (29 f). Of this species there are now some more specimens of both sexes before me from the Coll. FASSEL. The ♂ has much smaller hindwings with an extended anal angle; the turned over proximal margin contains beneath, in a white, lustrous ground, an oval, light yellow scent-scale spot; the abdomen projects beyond the hindwings; in the ♂ the costal vein is fully developed, the upper radial vein coalesces with the subcostal. Perhaps the animal would anyhow be better placed with the *Arctianac*.

P. 148, line 4 from below, in *ossa* replace: (22 e) by (29 f). After the name insert as synonyma: *unbraticola* Klages of p. 149 line 6 from above, and: *nitens* Rothsch. of p. 163 line 14 from below (as *Agyrta*). After *ossa* insert:

C. germana Rothsch. (22 c as *ossa*) of p. 163 line 9 from below (= *ossa* Druce Biolog. nee 1893).

P. 148, line 1 from below, after *flaviventralis* insert:

C. buchwaldi Rothsch. (29 e) of p. 163 line 20 from below (as *Agyrta*) differs from the preceding by much less blue on the body, quite black, not blue, veins on the hindwing with a white proximal margin, white forehips and much smaller size.

C. acutipennis Rothsch. (29 e) of p. 163 line 18 from below (*Agyrta*).

P. 149, line 6 from above, eliminate *unbraticola*.

„ 149, „ 16 „ „ „ „ to *gymnelioides* add: (29 d).

„ 149, „ 20 „ „ „ „ after *gymnelioides* insert:

120a. Genus: **Osmoeneme** *gen. nov.*

This interesting, new genus is an intermediary between *Schasiura* and *Eupyra*. The forewings entirely correspond to those of the preceding, the discocellular, however, is placed considerably more obliquely. The hindwing shows a more pointed apex, a straighter distal margin and a somewhat extended anal angle; venation very much like *Eupyra*, but both the lower radial veins are on a long petiole. The erect, moderately long palpi have appressed hair; the hairing of the body like in *Schasiura*; the 1st abdominal ring shows laterally a large, soft tuft of yellowish woolly hair. Very characteristic are the posterior tibiae of the ♂: broadly expanded like leaves, the flatly basin-shaped inner side is padded with short, brownish-grey scent-scales. Only one species. Type: *O. bradata* Draudt.

O. bradata *sp. nov.* (29 d) strikingly resembles *I. pyroproctis* (29 d). Body quite black without any *bradata*. white spots, also the forehips are black, the 3 last rings orange-yellow. Wings likewise the same, but the forewing with a hyaline subcostal area, and towards the margin the fine black internerval stripes are absent. The hindwing shows a much narrower black margin, only at the anal angle it is broadened to a large black spot. Expanse of wings: 36 to 39 mm. A small number of specimens from East Colombia (Villavieencio and the Rio Negro) in the Coll. FASSEL.

P. 149, line 25 from below, to *distincta* add: (29 f).

„ 149, „ 8 „ „ „ „ „ *affinis* „ (29 g).

„ 150, „ 7 „ „ above, place *dorata* to *Calonotos*.

„ 150, „ 18 „ „ „ „ to *psittacus* add as synonym: *pinocha* Dogn. of p. 107 line 12 from above (*Phaeo*).

„ 150, „ 2 „ „ below, „ *grandis* add: (29 h).

„ 151, „ 9 „ „ above, eliminate *similis* as synonym to *Cyanopepla orbona*.

„ 151, „ 3 „ „ „ „ after *alonzo* insert:

C. egregia *sp. nov.* (29 h). Body black, suffused with a radiant greenish-blue; palpal base spotted *egregia*. white, forehips blue, spotted white. Venter with a white median stripe. Forewings black with a metallic greenish-blue stripe on the base of the inner-marginal vein, and traces of such scales at the costal base and below the median; from the distal half of the cell, below the median around as far as up to the middle radial, extends a reniform red spot traversed by the black veins. Hindwings black, in the disc with a violet-blue longitudinal stripe and before the middle of the margin with a large, oval, red spot. Fringes white. Expanse of wings: 37 mm. Described according to 1 quite fresh ♀ from the Rio Songo (Bolivia) (FASSEL).

P. 152, line 18 from above, eliminate *melinda* with the description.

„ 152, „ 14 „ „ below, to *orbona* add as synonymous: *similis* Heyl. of p. 151 line 9 from above.

„ 152, „ 6 „ „ „ „ „ *beata* add: (29 h). The description and figure exactly correspond to *G. ira* (p. 159. 26 i), so that I may presume that *beata* is to be replaced by the name *ira*.

- P. 153, line 10 from above, to *baroni* add: (29 h).
 „ 153, „ 2 „ below, „ *dognini* „ (29 i).
 „ 154, „ 4 „ above, „ *girardi* „ (29 i).
 „ 154, „ 8 „ „ „ *perspicua* „ (29 i).
 „ 154, „ 14 „ „ „ *hyaloptera* „ (29 i).
 „ 154, „ 16 „ below, „ *trita* „ (29 g).
 „ 154, „ 12 „ „ „ *metapolia* „ (29 f).
 „ 154, „ 8 „ „ „ place *nitens* to *Loxozona*.
 „ 155, „ 9 „ above, to *albicincta* add: (29 g).
 „ 155, „ 13 „ „ „ *klagesi* „ (29 g).
 „ 155, „ 19 „ „ „ *perptera* „ (29 g).
 „ 155, „ 21 „ „ „ *hoffmannsi* „ (29 g).
 „ 155, „ 24 „ „ „ *oceola* „ (29 g).
 „ 156, „ 3 „ „ „ after *euchromioides* insert:

C. cerealia Druce (29 h) (= *hampsoni* Dogn., *adamsi* Lathy) and insert the descriptions given for the synonymy, the former for the ♂, the latter with a red oblique band on the forewing for the ♀.

P. 156, line 25 from above, after *atbicosta* insert:

simsoni.

C. simsoni Druce (= *euchromioides* Hmps. ♀ nec ♂) (29 b) belongs to another section in which the ♀ exhibits, like in the ♂ of the I. section, a rudimentary middle radial, but without any bare places. The largest species with a broad red marginal band of the hindwing and an entirely red head. Expanse of wings: 64 mm. Colombia, Ecuador.

P. 156, line 26 from above, to *fida* add as another synonym: *venus* Prithw.

„ 156, „ 22 „ below, „ *engelkei* add: (29 h).

„ 153, „ 14 „ „ „ *alcedo*: I received a second specimen in the meantime from Cuba. The figure and description of *Napata chalybea* would fit well to it, but owing to the structure my specimens are for sure *Coreura* (pendant palpi, the upper radial of the forewing rising from far below the upper cell-angle, the subcostal vein of the hindwing before the upper cell-angle etc.)

P. 157, line 4 from above, to *flavicaput* add: (29 h).

„ 157, „ 25 „ „ „ eliminate *affinis* being synonymous to *bractea*.

„ 157, „ 28 „ „ „ to *caeruleonitens* add: (29 i).

„ 157, „ 18 „ below, „ *jonesi* „ (29 g).

„ 157, „ 13 „ „ „ *reducta* „ (29 i).

„ 157, „ 9 „ „ „ *albistriga* „ (29 k).

„ 158, „ 8 „ above, after *heber* insert:

mictochroa.

A. mictochroa Hmps. (29 i) is well characterized by the hindhead, sides of the collar and shoulders being spotted yellow, yellow anterior hips, white middle and posterior hips. The blackish-brown abdomen shows metallic blue lateral and orange ventral stripes. Expanse of wings: 34 mm. Brazil (Castro).

P. 158, line 16 from above, to *bractea* add as synonym: *affinis* Roths. of p. 157 line 25 from above.

„ 158, „ 23 „ „ „ *pydna* add: (29 i).

„ 159, „ 19 „ „ „ *delectans* „ (29 k) and insert after it:

seraphica.

E. seraphica sp. nov. (29 l) differs from the very closely allied *angelica* by the entirely black, blue-reflecting body including the anterior hips; the venter exhibits only a narrow, lavender-grey median stripe. The hyaline spot of the forewing is larger and broader, that of the hindwing is indicated by a very narrow, more thinly scaled place. Expanse of wings: 32 mm. Described according to 5 ♀♀ from the Rio Negro (FASL), from where also the typ. *angelica* originates.

P. 159, line 13 from below, after *chica* insert:

perpasta.

E. perpasta sp. nov. (29 k) is very closely allied to *chica*; it differs by its larger size; head and thorax including the palpi are quite black, only the forehead is white; metathorax and abdomen radiantly bluish-green with a golden reflection, above and beneath in the middle with a white longitudinal stripe. The subcostal space of the forewing hyaline, on the inner-marginal vein there is a broad bluish-green stripe. Hyaline spots otherwise like in *chica*. Expanse of wings: 35 mm. Described according to 1 ♀ from the upper Rio Negro (East Colombia) from the Coll. FASL.

P. 159, line 6 from below, to *klagesi* add: (29 k).

„ 159, „ 12 „ „ „ place *borcalis* to *Napata*.

„ 160, „ 7 „ „ „ before *ochrea* insert:

M. aetolia Druce (29 m) of p. 183 line 15 from above (*Eucereon*).

P. 161, line 5 from above, before *quadricolor* insert:

basalis.

M. basalis Wkr. (= *latona* Druce) (29 i). The body is black, in the neck orange, the abdomen with blue rings. The forewing with 2 blue basal dots exhibit a broad, orange-yellow median band, the hindwing a yellow disc. Expanse of wings: 30 mm. Colombia, Ecuador.

larissa.

M. larissa Druce (= *quadricolor* Hmps. part.) (23 k as *quadricolor*) is somewhat smaller than the following, the median band of the forewing removed more towards the margin and longer, the hindwing much more extensively yellow. Expanse of wings: 32 mm. Ecuador.

In **M. quadricolor** Wkr. the reference (23 k) is to be eliminated and replaced by (29 k). The species is larger, the median band of the forewing shortened, of a lighter yellow and nearer to the base. The hindwing has only one small spot in the cell. Expanse of wings: 36 mm. Venezuela.

M. albofasciata *Rothsch.* (29 k) of p. 189 line 6 from above (as *Propyria*) is likewise very similar. The median band of the forewing is white, situate before the middle, and extends from the costal margin to the proximal margin; the spot of the hindwing is placed more erect. Palpal base yellow. Expanse of wings: 36 mm. Peru, Bolivia.

- P. 162, line 11 from above, to *micilia* add the synonyma: *auro* *Hbn.* and *cottaris* *Ky.*
 „ 162, „ 17 „ „ , *garleppi* is a distinct species; add to it: (29 l).
 „ 162, „ 28 „ „ , to *bifasciata* add: (29 l).
 „ 162, „ 23 „ below, „ *klagesi* „ (29 l).
 „ 162, „ 17 „ „ , eliminate *abdominalis*, and line 12 *ockendeni*.
 „ 162, „ 8 „ „ , eliminate *semihyalina*.
 „ 163, „ 4 „ above, eliminate *rubroanatis*.
 „ 163, „ 9 „ „ , to *mathani* add: (29 k); it is said to be a distinct species; I am unable to find a difference.
 „ 163, „ 18 „ „ , *conspicua* add: (29 k).
 „ 163, from line 23 from above to line 6 from below eliminate: *birchi*, *pseudodelphire*, *buchwaldi*, *acutipennis*, *nilens*, *germana*, all of which belong to other genera.
 P. 163, line 5 from below, to *pulehriformis* add: (29 l).
 „ 164, „ 11 „ above, „ *varuna* „ (29 k) and the following species *lacteicolor* as synonym.
 „ 164, „ 18 „ below, „ *sanguipalpis* „ (29 l).
 „ 165, „ 8 „ above, „ *clongala* „ (29 m).
 „ 165, „ 21 „ „ „ *hebes* „ (29 m). The small species flies in Honduras, Porto Rico; Venezuela; Brit. Guiana and Brazil.
 P. 165, line 28 from above, to *minuta* add the synonyma: *trinita* *Schs.* of p. 172 line 2 from below (as *Eucercyon*) and *griseipuncta* *Rothsch.* of p. 169 line 8 from below (as *Heliura*). On line 31, *subsp. extensa* is to be eliminated and this form to be inserted after it as a distinct species by the name of: *boliviana* *Rothsch.* (29 l) of p. 174 line 17 from above (as a form of *Eucercyon melanoperas*).
 P. 165, line 15 from below, after *maculosa* insert:

D. arpi *Schs.* (30 b). The largest species with yellowish-white forewings spotted greyish-brown and *arpi*. provided with dentate lines. Hindwings greyish-brown, in and behind the cell with a transparent spot. Anterior body yellowish-white, spotted and marked greyish-brown; the abdomen is yellow, the first and the two last segments blackish, the first subdorsally spotted, the middle rings with black segmental margins being expanded above on the dorsum into spots. Expanse of wings: 46 mm. Brazil (Rio de Janeiro).

P. 165, line 6 from below, after *pusilla* insert:

D. parcipuncta *Hmps.* (= *meridionalis* *Rothsch.*) (29 m) of p. 170 line 20 from above (as a subsp. *Heliura stollii*).

D. pieroides *Rothsch.* (30 a) of p. 170 line 12 from above (*Heliura*).

D. distincta *Rothsch.* (29 m) of p. 169 line 15 from above (*Heliura*).

D. lemoulti *Rothsch.* (30 a) of p. 186 line 3 from below (*Heliura*).

P. 165, line 1 from below, to *albivenlus* add as synonym: *birchi* *Rothsch.* of p. 163 line 23 from above (as *Agyrta*). Insert hereafter as a species:

D. borealis *Rothsch.* (29 l) of p. 163 line 27 from above (as a subsp. of the preceding).

D. pumila *Rothsch.* (29 l) of p. 163 line 27 from above (as a subsp. of the preceding).

- P. 165, line 15 from below, to *roseiceps* add as synonym: *integrum* *Rothsch.* of p. 171 line 10 from above (as *Eucercyon*).
 „ 165, „ 6 „ „ „ *discalis* add: (29 m) and as synonym: *infraalba* *Rothsch.* (p. 167 line 24 from below).
 „ 166, „ 1 „ above, „ *aclytioides* add: (30 a).
 „ 166, „ 1 „ „ , in *varians* replace (24 a) by (30 a); the figure and description of the ♂ refer to another animal which is no Syntomid.
 P. 166, line 13 from above, *hampsoni* to which (30 a) is to be added, has to be regarded as a distinct species with the forms *orientalis* and *meridensis*.
 P. 166, line 24 from above, to *pyrozona* add: (29 m), and as synonym: *rubrocincta* *Rothsch.* of p. 169 line 22 from below (as *Heliura*).
 P. 166, line 25 from below, place *suffusa* to *Heliura*.
 „ 166, „ 16 „ „ „ after *macella* insert: *D. germana* *Rothsch.* (29 m) of p. 170 line 27 from above, and for „*sericea*“ compared with it read: *macella*.
 P. 166, line 16 from below, for *lemoulti* place the name *D. meridionalis* *Rothsch.* of p. 169 line 13 from above as *Heliura Klagesi meridionalis*.
 P. 166, line 9 from below, to *subapicalis* add: (30 b).
 „ 166, „ 2 „ „ „ *nigra* „ (30 b).
 „ 167, „ 10 „ above, „ *flaviventralis* „ (30 b).
 „ 167, „ 14 „ „ „ *flaviceps* „ (30 b) and as synonym: *Klagesi* *Rothsch.* of line 24.
 „ 167, „ 18 „ „ „ place *monotona* as synonymous to *lestacea*.
 „ 167, „ 24 „ below, eliminate *infraalba* being synonymous to *Dactyphre discalis*.
 „ 167, „ 19 „ „ , to *rhodocrypta* add (30 a) and as synonym: *klagesi* *Rothsch.* of p. 169 line 11 from above.
 „ 167, „ 12 „ „ . eliminate the sentence: „Probably — to the end!“ After *tetilla* insert:

D. boettgeri *Druce* (30 b) extremely resembles the preceding and differs by its more blackish-brown *boettgeri*. colour, beside the red ring of the neck also carmine hindhead, and a round, white apical spot of the forewing. Expanse of wings: 38 mm. Peru.

After it insert:

144a. Genus: **Mesocerea** Hmps.

The two species forming this new genus have been described as *Teucer*. They greatly approximate the preceding genus from which they differ on the forewing by the upper median vein rising from the corner of the cell, and by the two lower radials being petioled; the upper one comes from the upper cell-angle. On the hindwing the middle radial vein rises almost from the middle of the transverse vein. Beneath the ♂ hindwings are covered with rough scent-scales towards the margin.

M. distincta Rothsch. of p. 127 line 27 from below (as *Teucer*).

M. apicalis Rothsch. of p. 127 line 8 from below (as *Teucer*).

- P. 168, line 8 from above, to *assimilis* add: (30 b).
 „ 168, „ 11 „ „ „ *fulvipicta* „ (30 a).
 „ 168, „ 16 „ „ „ *elongata* „ (30 b).
 „ 168, „ 19 „ „ „ *umbrinaeula* „ (29 m).
 „ 168, „ 29 and 25 from below, place *dolens* and *postflavida* to *Cereopimorpha*.
 „ 168, „ 23 from below, to *fumata* add: (30 a).
 „ 168, „ 19 „ „ „ place *fuliginosa* to *Eedemus*.
 „ 168, „ 16 „ „ „ to *hecale* add as synonym: *picliceeps* Hmps. Insert after it:

Hyalucerea gigantea Druce (30 c) of p. 173 line 16 from below (*Eucereon*).

H. flavipunctata Dogn. (30 c) of p. 174 line 27 from above (*Eucereon*).

H. baleris Dyar (30 c) of p. 176 line 17 from above (*Eucereon*).

H. suffusa Lathy of p. 166 line 25 from below (*Delphyre*).

- P. 168, line 12 from below, place *eacruleocephala* to *Eucereon*.
 „ 168, „ 3 „ „ „ „ *lemoulti* to *Delphyre*.
 „ 169, „ 3 „ „ „ „ above, to *viridieingulata* add: (30 c). Insert after it:

H. excavata Dogn. of p. 171 line 15 from above (*Eucereon*).

H. flava Dogn. of p. 171 line 20 from above (*Eucereon*).

H. perexcavata Rothsch. (30 d) of p. 171 line 23 from above (*Eucereon*).

H. kennedyi Rothsch. (30 c) of p. 171 line 27 from above (*Eucereon*).

thysbodes. **H. thysbodes** Dogn. (30 c) greatly approximates *ockendeni*, from which it differs by more whitish forewings with yellow veins and costal margin, much darker hindwings with a slight, whitish, diaphanous brightening in the discal part. Expanse of wings: 40 mm. Colombia.

- P. 169, line 15 from above, place *distineta* to *Delphyre*.
 „ 169, „ 26 „ „ „ „ to *ockendeni* add: (30 d).
 „ 169, „ 22 „ „ „ „ below, *rubrocineta* is to be eliminated as synonymous with *Delphyre pyrozona*.
 „ 169, „ 17 „ „ „ „ place *rufipes* to *Eucereon*.
 „ 169, „ 8 „ „ „ „ after *balia* insert:

baliodes. **H. baliodes** Hmps. (30 c) differs from the preceding by its black head and thorax, only the vertex, collar and borders of the shoulder-covers being brownish-white; the abdomen, being red above, is black beneath and at the end, the lateral spots are absent. The hindwings are much more extensively dark, the macular marking of the forewing finer. Expanse of wings: 30 mm. French Guiana.

Insert after it:

H. marica Cr. of p. 172 line 11 from above (*Eucereon*).

H. postcoerulea Rothsch. of p. 172 line 17 from above (*Eucereon*).

H. amazonica Rothsch. (30 c) of p. 172 line 19 from above (*Eucereon*).

- P. 169, line 8 from below, eliminate *griseipuncta* as synonym to *Delphyre minuta*.
 „ 169, „ 2 „ „ „ „ place *hoffmannsi* to *Eucereon*.
 „ 170, „ 12 „ „ „ „ above, to *stolti* add: (30 d).
 „ 170, „ 12 „ „ „ „ place *pieroides* to *Delphyre*.
 „ 170, „ 20 „ „ „ „ „ *meridionalis* as *pareipuncta* to *Delphyre*.
 „ 170, „ 26 „ „ „ „ „ after *sanguipalpia* insert:

H. semihyalina Rothsch. (30 c) of p. 162 line 8 from below (*Agryta*).

mimula. **H. mimula** sp. nov. (30 d) strikingly resembles the preceding, but it is somewhat larger. The easiest discernible by the lower median vein of the forewing rising much nearer to the base and parting the oblong hyaline spot, whereas in *semihyalina* it defines it distally: the reniform subapical spot is larger. On the hindwing the hyaline spot is traversed by black veins, the proximal margin is broadly whitish hyaline. Head and palpi are quite blackish-brown, the forehead slightly white. The venter exhibits a broad, white median stripe, in *semihyalina* two sublateral stripes. Expanse of wings: 35 mm. Described according to 1 ♂ from the Rio Songo Bolivia (FASSEL).

- P. 170, line 27 from above, place *germana* to *Delphyre*.
 „ 170, „ 10 „ „ „ „ below, to *albitornia* add: (30 d).
 „ 171, „ 10 „ „ „ „ „ above, eliminate *integrum* as synonym to *Delphyre roseiceps*.
 „ 171, „ 15 to 27 from above, place *excavatum* as far as *kennedyi* to *Heliura*.
 „ 171, „ 23 from below, to *cinetum* add: (30 d).
 „ 171, „ 20 „ „ „ „ „ „ *rubroanale* „ (30 e).

- P. 171, line 6 from below, place *lemoulti* to *Hyaleucerca*.
 „ 171, „ 3 „ „ „ to *meruloides* add: (30 e).
 „ 172, „ 6 „ „ above, after *merula* insert:

E. caeruleocephala Rothsch. (30 e) of p. 168 line 12 from below (*Heliura*).

- P. 172, line 6 from above, place *fanum* to *Correbidia*.
 „ 172, „ 11 „ „ „ „ *maricum* to *Heliura*.
 „ 172, „ 25 „ „ „ „ after *appunctatum* insert:

E. facundum *sp. nov.* (30 e) differs from *appunctatum* above all by the absence of the white spot *facundum*. at the cell-end of the forewing and the entirely black abdomen, in which only the upperside of the 4 last rings is red; the ♂ antennae are only half as long-combed, the shape of the wings is much broader, obtuser, the distal margin by far not so oblique and long as in *rosenbergi*, which is supposed by HAMPSON to belong to *appunctatum*; of the latter only a ♀ seems to be known, so that I cannot judge of the antennae; at any rate, those of *rosenbergi* are extremely long-combed. Expanse of wings: 27 mm. 1 very fresh ♂ from Villavicencio (FASSEL).

E. rufipes Rothsch. (30 f) of p. 169 line 17 from below (*Heliura*).

- P. 172, line 25 from below, *rosadora* and *xanthodora* are only insignificant forms of *rosa*.
 „ 172, „ 2 „ „ below, eliminate *brinita* as synonym to *Dclphyre minuta*.
 „ 173, „ 3 „ „ above, to *rufidorsale* add: (30 f).
 „ 173, „ 11 „ „ „ „ *formosum* „ (30 f).
 „ 173, „ 16 „ „ „ „ *dognini* „ (24 l as *centralis*).
 „ 173, „ 18 „ „ „ „ eliminate *ruficollis*.
 „ 173, „ 24 „ „ „ „ *leriioides* is a distinct species and to be placed after *aoris* (p. 180 line 7 from below) with the reference (31 a).
 P. 173, line 25 from above, place *dilutius* Rothsch. as synonym to the following species: *taronia*.
 „ 173, „ 25 „ „ below, to *conspicuum* add: (30 g).
 „ 173, „ 16 „ „ „ „ place *giganteum* to *Heliura*.
 „ 173, „ 11 „ „ „ „ to *punctatum* add as synonym: *ruficollis* of p. 173 line 18 from above.
 „ 173, „ 11 „ „ „ „ take out the synonym *zamora* as a distinct species with *punctatum* Hamp. as synonym *zamora*. and add: (30 g) to it. It is larger with lighter forewings. Expanse of wings: 40 mm. Guatemala; Ecuador.
 P. 173, line 6 from below, to *buchwaldi* add: (30 f).
 „ 174, „ 4 „ „ above, „ *leprotum* „ (30 d).
 „ 174, „ 10 „ „ „ „ *fosteri* „ (30 f).
 After it insert:

E. fassli *sp. nov.* (30 g). Head and collar blackish-brown, the latter with minute grey spots. Thorax *fassli*. light grey with fine black stripes, metathorax and hindhead scarlet like the abdomen above; the latter has a triangular, brownish-grey basal spot and a black terminal segment; venter and legs black. Forewing light-grey with fine black veins, 3 strongly curved transverse lines, fine black oval annular and reniform maculae in the cell and before the margin 3 brownish-grey spots. Hindwings darker grey. Expanse of wings: 33 to 35 mm. A small number of specimens from the Upper Rio Negro (East Colombia) in the Coll. FASSEL.

- P. 174, line 20 from above, place *bolivianum* to *Dclphyre*.
 „ 174, „ 21 „ „ „ „ to *rosenbergi* add: (30 e).
 „ 174, „ 23 „ „ „ „ „ *pallada* „ (30 e).
 „ 174, „ 27 „ „ „ „ „ place *flavopunctatum* to *Heliura*.
 „ 174, „ 23 „ „ below, to *dorsipunctum* add: (30 e).
 „ 174, „ 9 „ „ „ „ eliminate *centralis* (= *formosum dognini*).
 „ 174, „ 1 „ „ „ „ „ after *atriguttum* insert:

E. capsicum Schs. (30 g) greatly resembles the preceding, from which it differs by its more purely *capsicum*. white ground-colouring, purely white forehips, dark-banded red abdomen with black lateral spots, somewhat differently arranged smaller spots on the purely white forewing and more diaphanous hindwings. Expanse of wings: 32 mm. Brazil (Castro Paraná).

- P. 175, line 1 from above, to *marcatum* add: (30 f).
 „ 175, „ 20 „ „ „ „ after *imrii* insert:

E. wernickei *sp. nov.* (30 h). Head and thorax greyish brown, in the neck 2 small vermilion spots. *wernickei*. Abdomen above carmine with a blackish-brown, triangular basal spot; the last ring and a broad lateral stripe velvety-black; the first palpal joint, the hips and ventral side are light yellow-reddish. Forewings brown with exactly the same scheme of markings as in *complicatum*, though the markings are finer and the light places are absent at the cell-end and before the margin. Hindwings blackish-brown, in, below and behind the cell diaphanous lighter. Expanse of wings: 39 mm. 1 ♂ from Sa. Catharina (Brazil) from the Coll. WERNICKE.

- P. 175, line 27 from below, in *sylvius* eliminate the synonym: *lutulentum*; after it insert as a distinct species:

E. lutulenta Mschlr. is much lighter than *sylvius*, in which the forewings are almost black with *lutulenta*. fine lighter linear markings, whereas here they are greyish-brown, with dark spots. The abdomen is more scarlet, beneath brown, only the 3 first rings are whitish-rosy; the black lateral stripes are absent. Expanse of wings: 36 mm. Surinam; Brazil. Amazon.

- P. 175, line 21 from below, to *antonia* add: (30 f).
 „ 175, „ 3 „ „ „ „ „ *hampsoni* „ (30 f).
 „ 176, „ 1 „ „ above, „ *tessellatum* „ (30 k).
 „ 176, „ 4 „ „ „ „ „ *cimonis* „ (30 h).

- P. 176, line 17 from above, place *bateris* to *Hetiura*.
 „ 176, „ 20 „ „ „ to *flemmingi* add: (30 g).
 „ 176, „ 22 „ below, „ „ *obliquifascia* „ (30 g).
 „ 176, „ 7 „ „ „ *patulum* „ (30 h).
 „ 176, „ 3 „ „ „ *servator* „ (30 h).

After it insert:

assutum.

E. assutum *sp. nov.* (30 h) entirely resembles *patrona* in the colouring and marking of the thorax and forewings, but the ground-colouring is lighter, almost whitish-grey. The abdomen, however, is ochreous-yellow with a brown, triangular basal spot; the other rings are quite unspotted, only the last ring and a part of the penultimate ring velvety black, as well as a broad lateral band. Venter yellowish-white, the 3 last rings curled black. Expanse of wings: 44 mm. 1 ♀ from the Rio Songo (Bolivia) (FASSEL).

P. 177, line 5 from above, after *casca* insert:

colombiac.

E. colombiae *sp. nov.* (30 k) differs from the preceding by narrower, longer wings, a metallic blue forehead, the absence of the orange spots in the neck; the metathorax not being spotted white, and the abdomen quite unicolorously blackish-brown without the yellow anal apcx, the first 3 rings beneath spotted white. The veins on the forewing are more brightly and finely striped orange, the whitish spot behind the cell-end broader, rounder. Expanse of wings: 38 mm. Described according to 1 ♀ from Medina (East Colombia) (FASSEL).

The species *casca* as far as *albinotum* incl. are better placed farther back near *aroa*.

- P. 177, line 6 from above, to *pseudocasca* add: (30 k).
 „ 177, „ 10 „ „ „ „ *albinotum* „ (30 k).
 „ 177, „ 24 „ „ „ „ *bricnoi* „ (30 i).
 „ 177, „ 24 „ „ „ „ *griseatum* „ (30 i).
 „ 177, „ 22 „ below, „ „ *xanthurum* „ as synonyma: *schausi* Roths. of p. 182 line 12 from above and *apicaflava* Kaye of p. 177 line 19 from below.
 P. 177, line 14 from below, to *decorum* add: (30 i).
 „ 177, „ 6 „ „ „ „ *surcatum* „ (30 i).
 „ 178, „ 2 „ above, „ „ *atratum* „ (30 k); it is a distinct species.
 „ 178, „ 4 „ „ „ „ *simite* „ (30 k).
 „ 178, „ 14 „ „ „ „ *albidius* „ (30 l).
 „ 178, „ 12 „ below, „ „ *perstriatum* „ (30 m).
 „ 179, „ 3 „ above, „ „ *picoides* „ (30 l).
 „ 179, „ 10 „ „ „ „ *tigrata* „ (30 k).
 „ 179, „ 13 „ „ „ „ *consortum* „ (30 l).
 „ 179, „ 23 „ „ „ „ *tigrisoma* „ (30 l).
 „ 179, „ 24 „ below, „ „ *ockendeni* (30 l).
 „ 179, „ 15 „ „ „ „ *steinbachi* „ (31 a); this species is better placed more in front to *pseudarchias*.
 „ 179, „ 10 „ „ „ „ *setosum* place the following *mara* as synonym.
 „ 179, „ 6 „ „ „ *relegatum* Schaus (30 m) is a distinct species.
 „ 180, „ 1 „ above, eliminate *cubense* as synonym to *carolina*.
 „ 180, „ 10 „ „ „ „ from *confine* the reference (25 f) is to be taken away and substituted by (30 m). *confinis* H.-S. has become known only from Brazil, Colombia and Peru, it has still more purely white forewings and in the ♂ almost purely white, somewhat diaphanous hindwings with a narrow black border; in the ♀ they are dusted darker.
 P. 180, line 13 from above, *carolina* is to be regarded as a distinct species with the reference: (25 f as *confine*); add hereto as synonyma: *cubense* Schs. (line 1 from above) and *confusum* Roths. (line 15 from above), in the latter of which the reference: (25 g) is to be eliminated.
 P. 180, line 18 from above, *amazonum* (30 m) is a distinct species and is most closely allied to *moeschleri* from which it differs by its more olive-brownish, not so ochreous-yellow colouring and deeper black spots, which are much larger in the cell-end.
 P. 180, line 23 from above, to *moeschleri* add: (25 g as *confusum*).
 „ 180, „ 27 „ „ „ „ *parambae* add: (30 m), and eliminate: (25 g) which refers to a new species:

seitzi.

E. seitzi *sp. nov.* (25 g as *parambae*). Smaller than the preceding with longer, more pointed wings. Head and thorax of a purer yellowish-grey, shoulder-covers striped black. Forewings whitish-grey, on the veins broadly striped olive-brownish, the scheme of markings similar as in the preceding, spots on the whole larger, more oblong, in the basal part a little different; in the submedian area the spots of the subbasal transverse band are contiguous with those of the antemedian band, forming an oval figure; before the middle of the cell there is a remarkable, round spot. Hindwing in the basal part very light, whitish. Abdomen ochreous-yellow, above on the last ring with a blackish-brown spot, the anal hairing again ochreous-yellow. Venter greyish-brown, the anterior rings laterally with large whitish spots. Expanse of wings: 23 mm. 2 ♂♂ from Bolivia in the Coll. SEITZ.

- P. 180, line 15 from below, to *ochrotum* add: (30 m).
 „ 180, „ 13 „ „ „ „ place *popayanum* to *Pseudactytia*.
 „ 180, „ 2 „ „ „ „ to *inconspicuum* add: (30 l).
 „ 181, „ 3 „ above, „ „ *ecuadoris* „ (30 m).
 After *flavicincta* insert:

crambidinum.

E. crambidinum *sp. nov.* (31 a) is a small, delicate, pale insect, the body and forewings coloured light grey, the forehead somewhat darker brownish-grey; the penultimate abdominal segment exhibits small, subdorsal, yellow spots. Forewings on the veins and folds finely striped darker; markings besides: a round spot in the middle of the cell, two at the cell-end and one above them at the costal margin; behind the cell-end and below it very indistinct, long-extended nebulous spots; an antemarginal series of spots: 3 somewhat darker

ones between the middle radial and the costal margin, below they are smaller and more indistinct, between the lower radial veins projecting far towards the margin, then running very obliquely to the middle of the proximal margin; in the marginal area there are somewhat darker scales interspersed. Hindwings white, thinly scaled, with a grey marginal band widening at the apex. Expanse of wings: 28 mm. Described according to 2 fresh ♀♀ from the Rio Negro (East Colombia); Coll. FASSL.

P. 181, line 23 from above, to *sadana* add: (31 a).

„ 181, „ 26 „ „ „ „ *mathani* „ (31 a), and the synonym: (*fuscatum* Rothsch.) of p. 182, line 23 from above.

P. 182, line 5 from above, to *scyton* add: (31 a); (25 i) made according to CRAMER's figure ist not recognizable. Add besides to it as synonym: (*mizar* Druce) of p. 182 line 11 from below.

Insert hereafter:

E. parascyton *Hmps.* (31 a) differs from the preceding by its white-margined forehead, black-striped *parascyton*. shoulder-covers, the forewings being of a purer whitish, with an olive-brown tint in the basal halves, the base itself black; the transverse lines more shadowy; instead of the light spot behind the cell there is blackish dusting. Expanse of wings: 28 mm. Peru.

P. 182, line 12 from above, eliminate *schausi* as synonymous to *xanthurum*.

„ 182, „ 23 „ „ „ eliminate *fuscatum* as synonymous to *mathani*.

„ 182, „ 27 „ „ „ to *fuscobrunneum* add: (31 b).

„ 182, „ 24 „ below, „ *fuscoirroratum* „ (31 b).

„ 182, „ 22 „ „ „ *minor* is to be placed as synonym to **E. brunneum** Rothsch. which is to be inserted here, with the reference: (31 b), of p. 128 line 12 from above (as *Teucer*).

P. 182, line 20 from below, to *strix* add: (31 b).

„ 182, „ 14 „ „ „ „ *ino* „ (31 b).

„ 182, „ 11 „ „ „ „ eliminate *mizar* as synonymous to *scyton*.

„ 182, „ 8 „ „ „ „ to *resina* add: (31 c).

„ 182, „ 5 „ „ „ „ *ignotum* „ (31 a).

„ 182, „ 2 „ „ „ „ *irroratum* „ (31 c).

„ 183, „ 3 „ above, eliminate *testaceum* as synonymous to *lineatum*.

„ 183, „ 6 „ „ „ „ after *testaceum* insert: *hoffmannsi* Rothsch. (31 b) of p. 169, line 2 from below (as *Heliura*).

„ 183, „ 6 „ „ „ „ to *zephyrum* add: (31 c).

„ 183, „ 19 „ „ „ „ *phaeoproctum* „ (25 i).

„ 183, „ 15 „ „ „ „ place *aetolia* to *Micragra*.

„ 183, „ 22 „ „ „ „ to *venosum* add: (31 c).

„ 183, „ 28 „ „ „ „ *intranotatum* „ (31 c).

„ 183, „ 17 „ below, „ *birchelli* „ (31 c).

Insert hereafter:

E. perplicatum *spec. nov.* (31 b) forms about the intermediary between *birchelli* and *fuscoirroratum*. *perplicatum*. Body and forewings fawn-coloured, on the head somewhat lighter yellowish, on the abdomen darker, posteriorly with a slight steel-blue reflection. Palpi anteriorly black, interiorly and at the base of the terminal segment white. Legs blackish-brown, at the ends of the tibiae and tarsi white-ringed. The abdomen shows whitish lateral stripes. Forewings densely strewn with brown scales; they exhibit 3 indistinct, oblique transverse stripes, the antemarginal one more in the shape of a broad shade, the two others are dotted dark on the ribs; in the lower half of the transverse vein there is a dark dot; the apex is parted by an oblique streak; before the margin between the veins small dashes, on the margin similar ones at the ends of the veins. Hindwings brownish-grey, towards the base somewhat lighter. Antennae at the ends above white, before them blackish. Expanse of wings: 35 mm. Described according to 1 ♂ from the Coll. WERNICKE from Sa. Catharina (Brazil).

E. insitivum *sp. nov.* (31 c) is somewhat like the preceding and resembles also *Pseudaclytia popayana*. *insitivum*. Anterior body and forewings light brown. Abdomen above ochreous-yellow with large, blackish-brown transverse spots being confluent on the anterior rings. Ventral side whitish with a broad, blackish-brown median stripe, at the sides small black spots. Forewings with darker veins and 3 similar transverse stripes as in the preceding; the space between the two distal ones darkened. Apex of the wing parted by black; at the upper and lower cell-angles one dark dot each. Hindwings grey-brownish, thinly scaled. Expanse of wings: 30 mm. 1 ♀ from Villavicencio (Colombia) in the Coll. FASSL.

E. sarisa *sp. nov.* (31 d). I am sorry to say that I am unable to ascertain the position of this most *sarisa*. peculiar insect, since only 1 fresh ♂ is before me (FASSL). The strangest mark is probably an organ, to be explained as a secondary sexual distinction, on the under surface of the forewing. The cell in its upper half is here covered with long yellowish scales, whereas in the lower half there rise erect, more hair-like, deep dark brown scales from the whole cellular length of the median, about like a prolonged female retinaculum; they conceal a lancet-shaped, white, somewhat diaphanous formation extending almost to the end of the cell, with longitudinally-grooved channels, looking something like the blade of a grass; proximally it disappears beneath the remarkably strong male retinaculum which as usually rises from the costal. On trying cautiously to move the frenulum, it seems also to move, so that it might be considered as an uncommon development of the retinaculum; I can, however, as stated above, not ascertain this now without risking to damage the specimen. Anterior body and forewings are brown; hindhead, neck, palpal base, and throat are ochreous-yellow, so is the upper side of the abdomen exhibiting black transverse spots which are more or less confluent on the anterior rings and covered by the brown hair of the base. Chest and venter whitish, legs somewhat more brownish. The forewings are veined indistinctly darker; the centre is crossed by a faded transverse band being broken almost

rectangularly at the lower cell-angle. Hindwings blackish-grey, in the disc somewhat more thinly scaled, at the costal margin and the fringes brown. Expanse of wings: 28 mm. 1 ♂ from Villavicencio (East Colombia) from the Coll. FASSL.

- P. 183, line 10 from below, to *lineatum* add: (31 e), and as synonym: (= *testaceum* Druce) of p. 183 line 3 from above.
 „ 183, „ 3 „ „ , for *hoffmannsi* place the name *pagina* Hmps. with the reference: (31 d).
 „ 184, „ 1 „ „ above, for *rothschitdi* which becomes a synonym insert the name: *chloraenoma* Hmps.
 „ 184, „ 9 „ „ , to *zizana* add: (31 d), and as synonym: *carabayanum* Schaus of p. 184 line 20 from above.
 „ 184, „ 12 „ „ , „ *nervulum* „ (31 d).
 „ 184, „ 15 „ „ , „ *nubilosum* „ (31 d).
 „ 184, „ 20 „ „ , eliminate *carabayanum* as synonym to *zizana*.
 „ 184, „ 27 „ „ , to *sordidescens* add: (31 e).
 „ 184, „ 22 „ „ below, „ *caeruleocaput* „ (31 d).
 „ 184, „ 11 „ „ , after *nebulosum* insert:

apicale.

E. apicale Wkr. (31 f). This species, having been originally described as *Halesidota*, has a brownish head with a red vertex; thorax and base of abdomen ochreous-brownish, the latter towards the apex warming into carmine; anal tuft black. Forewings ochreous-brownish with small, dark dashes at the middle of the proximal and costal margins, and before the apex; at the transverse vein likewise small dark spots. Hindwings diaphanous lighter. Expanse of wings: 34 mm. Brazil (*Castro*).

- P. 185, line 1 from above, to *postflava*: genus and species are better inserted between *Herea* and *Eumenogaster* (p. 122).
 „ 185, „ 23 „ „ , „ *bricenoi* add: (31 e).
 „ 185, „ 21 „ „ below, after *oberthueri* insert:

negrana.

C. negrona sp. nov. (31 e) is perhaps only a local form of *oberthueri*. Body unicolorously brownish-black with a slight slate-blue reflection, which grows more intense towards the anus. Legs at the ends of the joints spotted white. Forewings thinly scaled, black with interspersed slate-blue scales in the costal-marginal half, not transversely watered. Veins, towards the margin, darker, costal base orange; a postmedian, narrow, orange-brownish transverse band which vanishes towards the proximal margin and forms a tooth distally on the lower radial. Hindwings sooty black, in the disc thinly scaled with an orange costal spot. Expanse of wings: 39 to 40 mm. 2 ♂♂ 1 ♀ from the Rio Negro (Colombia) (FASSL).

- P. 185, line 12 from below, eliminate the name *intermedia*, and replace *elongata* Roltsch., since *elongata* Dogn. belongs to the genus *Rhynchopyga*. Add to it: (31 e).
 P. 185, line 8 from below, *boliviana* is only an insignificant local form of *tycoides*, and does not belong to *elongata*.
 „ 186, „ 6 „ „ above, to *semitransversa* add: (31 e).
 „ 186, „ 20 „ „ below, after *raea* insert:

meridionalis.

C. meridionalis Rothsch. (31 c) of p. 187 line 11 from below, which is a distinct species and belongs to *Correbia*.

- P. 186, line 19 from below, to *flavala* add: (31 f).
 „ 186, „ 12 „ „ , „ *felderi* „ (31 f).
 „ 186, „ 9 „ „ , „ *obscura* „ (31 g).
 Insert hereafter:

tristitia.

C. tristitia Kaye (= *klagesi* Rothsch.) which belongs here, not to the following genus. The ♂ shows a long hair-tuft in the middle of the proximal margin.

- P. 186, line 4 from below, place *elongata* to *Rhynchopyga*.
 „ 187, „ 8 „ „ above, before *notata* insert:

fana.

C. fana Druce (31 i) of p. 172 line 6 from above. This animal, being most conspicuous as a Syntomid is now placed to *Correbidia* by HAMPSON. According to a ♂ before me from the Coll. FASSL, originating from the Upper Rio Negro in Colombia, the animal would have to be placed to *Correbia*, owing to its hindwings, since the lower radial and upper median vein rise distantly remote from each other, whereas the veins of the forewings correspond exactly with those of *Correbidia*.

- P. 187, line 14 from above, to *assimilis* add: (31 g).
 „ 187, „ 17 „ „ , „ *similis* „ (31 g).
 „ 187, „ 19 „ „ , „ *steinbachi* „ (31 f).
 „ 187, „ 22 „ „ , „ *simonsi* „ (31 f).
 Insert hereafter:

germana.

C. germana Rothsch. (= *calopteridia* Druce nec Btlr., *terminalis* subsp. 1 Hmps., *continentalis* Draudt) (26 a as *continentalis*), which is a distinct species and is therefore to be eliminated as *subspecies* in *terminalis* (p. 187 line 15 from below).

- P. 187, line 24 from above, place *tristitia* to *Correbia*.
 „ 187, „ 8 „ „ below, to *castinotala* add: (31 f).
 „ 188, „ 1 „ „ above, „ *apicalis* „ (31 f).
 Insert hereafter:

bicolor.

C. bicolor H.-S. (31 h). Described as *Charidea*, from Cuba. Forewings unicolorously orange, hindwings lighter, diaphanous, with a brownish-grey margin. Head black with orange sides, thorax orange, abdomen black, at the sides and venter orange, the latter with a series of faded, brownish-grey bands. Expanse of wings: 24 mm.

P. 188, line 17 from above, to *cocklei* add: The full-grown larva is above grey with a black dorsal line and orange sub-dorsal lines; sides black with a light-yellow line below the stigmata; hairing brownish-grey, on the rings 2, 11 and 12 longer and jet-black; lives on grasses in September and October.

P. 188, line 20 from above, after *wrighti* insert:

S. coprea *sp. nov.* (31 g) is on the body and forewings unicolorously blackish-brown with a slight *coprea*. purple lustre. The abdomen reflects posteriorly somewhat blue. The hips and a broad ventral stripe are yellowish-white. On the forewing, in the lower half of the transverse vein, there is a minute, yellowish-white dot. Hindwing sooty black, in the disc hyaline diaphanous. Expanse of wings: 31 mm. Described according to 1 ♂ from the Coll. WERNICKE from Sa. Catharina (Brazil).

P. 188, line 24 from below, to *subhyalina* add: (31 h).

„ 188, „ 8 „ „ „ „ *normani* „ (31 g).

„ 188, „ 5 and 2 from below, place *ockendeni* and *nigrirufa* to *Napata*.

„ 189, „ 1 from above, before *atroxantha* insert:

P. pelopia *Druce*, described as *Talara*. Body black, only the palpal base, forehead and shoulder-covers *pelopia*. orange. Forewings orange, dusted brownish with a black border projecting with a pointed tooth to the upper cell-angle; proximal margin finely black. Hindwing black, in the costal half as far as beyond the middle orange. Expanse of wings: 24 mm. Panama.

P. 189, line 1 from above, after *atroxantha* insert:

P. criton *Druce*, described as *Cisthene*. Head and thorax black, spotted carmine on the shoulder- *criton*. covers; abdomen black with a green reflection. Forewings black, hindwings metallic blue with a black proximal margin and border. Expanse of wings: 22 to 26 mm. This little species has become known from Mexico and Guatemala. On the under surface of the hindwing there may occur white colour as a small spot at the lower cell-end or the whole wing may turn white except the black border. The latter form may be denominated: *hypoleuca* *form. nov.* (= ab. 2 *Hmps.*). *hypoleuca*.

P. 189, line 6 from above, place *albofasciata* to *Mevania*.

„ 189, „ 22 „ „ „ to *drucei* add: (31 g), and as synonym: *erythrophora* *Druce*.

„ 189, „ 20 „ „ below, after *pholus* insert:

L. deserta *Edw.* differs from *pholus* in the ♂ by a narrower black marginal band; the hindwings also *deserta*. have a narrower margin extending at the proximal margin as far as the base; palpi and base of tibiae orange. The ♀ which was captured in copula with the ♂, is coloured remarkably different: on the body and wings orange; the forewing shows a broad, black transverse band behind the base and another one from the costal margin beyond the middle to the proximal angle. Expanse of wings: ♂ 19 mm, ♀ 32 mm. The only couple apparently known was captured in Arizona.

P. 189, line 12 from below, *schausi* *Rothsch.* is a distinct species. Head and thorax blackish-brown, suffused with a metallic blue, with red stripes on the shoulder-covers, the blackish-brown abdomen with blue ring-indentations. Fringes of the wings at the apex and proximal angle white. Add to it: (31 g).

P. 189, line 5 from below, to *popayana* add: (31 h).

„ 189, „ 2 „ „ „ „ *garleppi* „ (31 h).

„ 190, „ 11 „ „ above, „ *mennisata* „ (31 h).

„ 190, „ 14 „ „ „ „ *albipars* „ (31 h).

„ 190, „ 17 „ „ „ „ *biformis* „ (21 d, as *abbreviata*).

„ 190, „ 10 „ „ below, „ *jonesi* „ (31 k).

„ 190, „ 7 „ „ „ „ *andrei* „ (31 k).

Insert after it:

C. manuela *Jones*. Body blackish-brown, palpal base and hindhead orange, abdomen suffused with *manuela*. blue, with an orange anal tuft; on the mesothorax with a fine, white longitudinal stripe; abdomen beneath banded white. Forewing blackish-brown with fine grey veins and a cuneiform, white postmedian spot. Hindwings reflecting blue, with white fringes. Expanse of wings: 38 mm. Brazil (Santos).

C. nana *Jones* greatly resembles the preceding, but it is somewhat smaller and of a lighter olive-brown *nana*. colour; beside the thorax also the shoulder-covers are striped white. Expanse of wings: 32 to 36 mm. Brazil (Santos).

P. 190, line 4 from below, to *mortia* add: (31 k).

„ 191, „ 1 „ „ above, „ *reimoseri* „ (31 g).

„ 191, „ 9 „ „ „ „ *subsemistria* „ (31 g).

„ 191, „ 25 „ „ „ „ *venosa* add as synonym: (= *tigrina* *Streck.*).

„ 191, „ 20 „ „ below, „ *tucumana* being a distinct species add: (31 i).

„ 191, „ 16 „ „ „ „ *reducta* add: (31 i).

„ 191, „ 13 „ „ „ „ *erissonana* „ (31 i).

„ 192, „ 14 „ „ above, „ *fosteri* „ (31 h).

„ 192, „ 17 „ „ „ „ eliminate *conchyliata* (= *Nap. sanguicincta*).

„ 192, „ 22 „ „ „ „ to *affinis* add: (26 k).

„ 192, „ 24 „ „ below, *albolineata* *Druce* (publ. April 1904) becomes synonymous, *projecta* *Dogn.* (publ. March 1904)

being the right name; add to it: (31 h).

P. 192, line 9 from below, to *cubana* add: (31 l).

4. Family: Arctiidae, Tiger Moths.

The number of American *Arctiidae* is very considerable, if one includes the groups having been branched off by others as *Hypsiidae* etc. This has been done here, referring to the fact that the venation of the Arctiids has not been awarded the leading part which is indisputably the case in other groups. I have already hinted at this in Vol. II, p. 43, and in Vol. 10, p. 105. An application upon the American fauna would mean a system based upon exclusive relations in the veins, as for instance the elimination of the *Pericopini*, as it effected in the palearctic regions the elimination of the *Callimorpha*, in the Indian region that of the *Aganais* from the family of the Arctiids; in spite of HAMPSON's precedence, we cannot make up our mind to such a bold proceeding.

We must, however, point out that neither the variegated colouring nor the hairy dress of the larva have been the reason why we inserted the *Callimorphini*, *Pericopini*, *Hypsiini*, *Phaegopterini* etc. among the *Arctiidae*. We find an Arctiid-like monitory exterior also in the ♀♀ of the Lymantriids (*Numenes separata* Vol. II, t. 22 f), in Agaristids and many Geometrids. But a close alliance seems to us to be exhibited by the conformities of details that are difficult to consider as the symptom of convergency. The very uniform smell of oil noticeable in the genuine *Arctiini* as well as in the *Callimorpha*, the *Aganais* and *Pericopis*, is produced by the development of a sharp, protective, yellow secretion emanating in thick drops from two apertures in the neck of the insect, a symptom which seems to be of quite a similar nature and of exactly the same effect in the *Callimorpha*, the *Arctia*, *Spilosoma* etc. In the *Apantesis*, *Arctia* etc. a large, yellow drop flows from the sides of the neck, on being disquieted, in certain *Pericopini*, the secretion profusely intermixed with air is discharged by jerks as a yellow foam, whilst the insect is groaning and moaning. It has an acid, somewhat caustic taste and protects these insects against their enemies to such an extent that they do not hide, but show themselves in a most conspicuous way by glaring colours, and often play in broad daylight, evidently shunned.

Another conformity of the *Callimorphini*, *Hypsiini*, *Pericopini* etc. with the *Arctiini* consists in a peculiar, cracking noise produced by the insects in flying. It is not equally audible to the human ear in all the species, but in many *Arctia*, in *Nyctemera* and *Aganais* it is distinct, and in *Parasemia plantaginis*, *Callimorpha dominula*, *Spilosoma* (*Dionychopus*) *niveum* even loud.

The larvae are all well haired, though not all are shaggy or furry. The hairs are mechanically undoubtedly quite a good protection, chemically, however, of very little effect. They also seem generally to have the purpose of a mechanical effect, for they are often very strong; *Arctia* has fleece-like compact hair which in *Ecpantheria* already grow so hard that they have the effect of spikes, while in the *Pericopini* they are still more specialized. The latter insects are covered with them in the shape of almost steel-hard, brittle, pointed thorns, which are not ramulous like those of the day-butterflies of or the *Dirphia* and *Automeris*, but not less pointed than those, and by which one is easily stung on touching the insect carelessly. Safeguarded by this protection, the larvae of the *Arctiidae* mostly live quite freely, feed in the sunshine, sit freely on the earth or on their food-plants in day-time, and but few, such as some *Ocnogyna*, *Cletis*, *Callimorpha* etc. hide superficially during the day.

Common to nearly all the *Arctiidae* is the behaviour and exterior of the pupa. It is mostly as smooth and bright as a mirror, as if it were polished, but by no means so thick-shelled as we find it in most of the other pupae of a porcelain lustre, the *Bunaea*, *Gynanisa*, *Agarista* etc. The web is very scanty, sometimes it does not even deserve this name and is then confined upon some criss-cross threads in which the pupa is hung up almost without any protection. In some species, such as *Arctia hebe*, *Rhyparia purpurata*, *Hyphoraia aulica* etc. it is to be wondered at how the little protected and rather delicate pupa is exposed to the roughness of the weather often increased by a severe winter. The pupae of the *Lithosiini* are shut off in a wide slit of the bark only by some cross threads, and consequently approachable to all their enemies. In a similar way, the pupae of *Aganais* being gregariously established in the slits of the bark are almost unprotected. The pupae of some *Pericopini*, however, are the most conspicuously and the most freely suspended in a few threads fixed between the tips of the twigs of isolated bushes, so that I occasionally thought to see a cobweb from the distance in the centre of which the pupa, as smooth as porcelain, was suspended like a spider.

Beside these peculiarities of peculiar conformity being found in by far the greatest part of the *Arctiidae* according to our conception there is also a far extending likeness noticeable in the contours of the wings, in the structure of the body, to a certain degree also in the colouring. We do not see anywhere mimicry, nor is there hardly ever any adaptation noticeable. The *Apantesis* shine brightly by their variegated colours, the *Lithosiini* by their yellow, the *Spilosoma* and *Haploa* by the snowy white, the *Belemnina* by their mag-

nificent, metallic spots, the *Ecpantheria* by their peculiar blue rings on a white ground, the *Automolis* by the strange patterns of their wings. Such a graceful, variegated appearance as is exhibited by the *Utetheisa*, *Seiractia*, *Chionaema* (*Bizone*), *Ambryllis boisduvalii* (*Arctia funeralis* H.-Schäff.), *Arachnis picta*, is even rare in the otherwise most variegated *Lepidoptera*-genera. The scheme of colouring as is exhibited by *Daritis sacrificia*, the ♀♀ of the Indian *Peridrome orbicularis*, the *Anaxita decorata* from Mexico, must be pronounced perhaps not as quite grotesque, but at any rate as quite out of the common.

In Vol. X (p. 105) a parallel is set up referring to the distribution of the colours in the Arctiid family on the two hemispheres. In the Old World we found the northern temperate zone to be the patria of numerous extremely variegated and brilliant species, whilst the hot zone is occupied by mostly insignificant, not very glaringly coloured forms. The comparison of the very variegated tables 16 to 18 in Vol. II (containing the palearctic *Arctiidae*) with the tables 19 to 25 in Vol. X (containing the Indo-Australian Arctiids) makes this behaviour easily recognizable. In the same way the magnificently coloured and marked nearctic genera of the Arctiids, such as *Apantesis*, *Hyphoraia*, *Platyprepia*, *Parasemia* etc. occur in North America, in order to disappear to the south where they are replaced by insignificantly yellow or white species (*Haploa*, *Hyphantria*, *Ecpantheria*, *Pygarctia*). Of more than 40 variegated *Apantesis* in the United States there is only one species in Mexico.

Further towards the south the genuine *Arctiini* disappear altogether, and also the *Spilosomatini* die away into insignificant, earth-coloured or grey forms of the genus *Antarchia* the ♀ of which is partly wingless. On the eastern hemisphere, in the southernmost parts (Australia and New Zealand) there appears once more the variegated type of the inclement north in the genera *Metacrias*, *Ardices*, *Phaos* (*Estigmene*) etc. which, however, is no more the case in South America.

In Tropical America there occur then Arctiids of another type (*Charideini*) in great varieties, moreover the *Automolis*, *Robinsonia*, *Idalus*, *Prumola* and their allies, the habitus of which sometimes already exhibits a relation to the *Halisidota*, an uncommonly multiform genus showing, however, very few singular markings and colours, which belongs to the *Phaegopterini* (with nearly 500 forms) and is altogether confined upon America. In the Old World there is no similar type found; the place it occupies in America has remained almost vacant on the eastern hemisphere; only a single genus consisting of few species, *Rhodogastris*, by the biological behaviour, the shape, and to some extent, also by the colouring reminds us of the ramous group of the *Phaegopterinae* in America. Not much is known yet of the larvae of the *Phaegopterinae*; but if there prevails with them the same conformity as with the butterflies of this group, all are probably distinguished by pencil-like or scopiform hair-brushes rising behind the head, on the second ring, and at the anal end of the larva. They are less complicated than the hairy pads, brushes and tufts of the *Automolis*, but they strongly recall the same hairy cover of the South American *Syntomidae*, where the anterior and posterior ends of the larvae are likewise decorated by pencil-shaped hair-tufts.

As to the group of the *Pericopini* we have already above mentioned some facts, further particulars will be given when dealing with this group. The approximately 150 forms reckoned hereto have a rather conformable structure and exactly the same habits. In contrast with the nocturnal *Phaegopterini* and *Charideini* they fly actively in daytime, in case they are chased up, although some have also been taken by the lamp, like in our European *Arctiidae*. As larvae they are decidedly day-animals.

The other groups composing the *Arctiini* of America are such that are also represented in the Old World and which have, therefore, all been already dealt with in Vol. II and Vol. X. These are the *Nolinae* differing little from the palearctic forms, and the *Lithosiinae* likewise exhibiting great conformity in their distribution over the world, as to their colouring, size, shape and also habits. The *Nyctemerinae*, being distributed on the eastern hemisphere do not occur in America, nor do the *Hypsinae* occur there. The *Callimorphinae* would be only American, if one places the *Platyprepia* or *Haploa* to them, which does not seem to me to be advisable. Entirely unparalleled in the west are the Papuan *Cocytia*, the relations of which to the Arctiid family we have denoted to be very loose, and the *Pterothysanus* placed to the *Nyctemerinae* by KIRBY, which, however, as we mentioned in Vol. X, p. 377, do not belong to them at all and which we have inserted in the Arctiids only by way of appendix.

The important part played by the *Arctiidae* in the Old World owing to the frequently very great number of specimens and to their conspicuous appearance, also appertains to them in America. Just like *Utetheisa pulchella* is mostly the first butterfly met with on setting one's foot on the southern coast of Europe or the northern coast of Africa, we are almost everywhere welcomed by *Utetheisa ornatrix* or *bella* on stepping on land in tropical America. At another place I have already mentioned that there exist certain common symptoms in the fauna at the most remote places of our globe, and the *Arctiidae* contribute their mite to it. Whether I disembark in Adelaide, in Ceylon or Hongkong, in Bahia or Algier, everywhere the *Utetheisa* will be productive of the first impressions made upon me. In the north I shall find the *Spilosoma* close above the soil, down on the planks, lanterns or socles, just as well in Tokio and Baltimore as in Germany. Only when I visit the rich vegetations of the gardens and woods, there appear the variegated *Arctiids*; in the Old World the *Callimorpha* and *Arctia*, in the west the *Pericopinae*. On knocking on trees and branches, there will appear everywhere *Lithosiinae* being alike each other; only in the (mostly nocturnal) Arctiid groups, such as the *Phaegopterinae* and the *Automolinae* America abounds by far more than the Old World.

Although there are groups among the American *Arctiidae*, that are much more closely allied to the preceding family of the *Syntomidae* than the *Nolinae* and *Lithosiinae*, we let them follow here at first, in order not to upset the conformity with the ranges of the other faunae. We then put the *Phaegopterini* in the place of the palearctic *Hypsinae*, and instead of the *Callimorphinae* and *Nyctemerinae* being absent in America and allied to the *Hypsinae*, we append there the *Pericopinae*, being likewise allied to them, whereby we obtain the following schedule:

- | | |
|--------------------------|------------------------|
| 1. Nolinae | 5. Spilosominae |
| 2. Lithosiinae | 6. Arctiinae |
| 3. Phaegopterinae | 7. Pericopinae |
| 4. Micrarctiinae | |

I. Nolinae.

The group of genera, of which the stock of American *Nolinae* is composed, comprises the very same genera representing this subfamily also in the other faunae, the genera *Nola*, *Roeselia* and *Celama*. Only a single species, *Nigetia formosalis*, has been assigned to another genus. America, with about 90 forms, possesses approximately half of all the *Nolinae* known; but according to DYAR's Catalogue, only 16 of them fall to the nearctic fauna conform to WALLACE's conception i. e. to the boreal parts of America to the south as far as the Mexican frontier. All the others are neotropical.

A general characterization of the subfamily has been given in Vol. II, p. 44 and supplemented in Vol. X p. 107. The statement made there, that the superficial habitus of the *Nolinae* strongly recalls that of certain microlepidoptera, refers also to the Americans, and this implies that *Nolinae* are captured only when hunting for microlepidoptera, while in the search for macrolepidoptera they are mostly overlooked.

In their size, shape, colouring, early stages, and habits the *Nolinae* of all the continents are so much alike, that the Americans among them need hardly be specially characterized. They are wont to sit, like certain *Acalta* (*Teras*), with their heads turned upwards on the trunks of trees and planks and do not like to fly in daytime, so that one is obliged to search for them carefully or to beat them out; at night they sometimes come to the lamp. The method of making the food-leaf recognizable by skeletonized feeding places is quite common to some Americans as well as to certain palearctic species, and the larva of *Celama triquetra* in North America leaves behind the same tell-tale traces of feeding on the leaves of *Hamamelis virginica* as the European *Roeselia togatulalis* do on oak-bushes.

Moreover, there is as yet very little known of the American species with respect to their life-history. About the South Americans we do not know anything at all, and from the United States HENRY EDWARDS only knew the food-plant and larva of *Celama sorghiella* and *ovilla*. The reason of our scanty knowledge of the *Nolinae*-larvae is partly based on their rareness and insignificance, but partly also in their living so very much concealed; even those few species that do not retire far into the density of the leaves, constantly hide during daytime on the underside of a leaf.

As to the peculiar habit of the larva not to cast off the head of the old skin when shedding their skin, but to carry it on a hair-pencil above the neck, we refer to Vol. X (l. c.). The scaphoid web is not only conspicuous by its shape, but also by its construction, since it is not woven round like other cocoons, but there are at first two walls erected and then this groove is covered with a roof, which method was already known to TREITSCHKE. In this casing the pupa lies being mesodorsally somewhat depressed. The imago, by the pads of erect scales, deviates from the other *Arctiidae*, except certain *Lithosiinae*, some of which, such as some *Chionaema* and the genus *Parelictis* exhibit conspicuous formations in the very same places of the forewings, where we find hairy pads in the *Nolinae*. In *Parelictis* (Vol. X, t. 18 i) this is a knob-like swelling near the cell-end, in *Chionaema pratti* (Vol. II, t. 12 c) a hair-curl on a fold of the wing.

Although we cannot infer a particularly close relation between the *Nolinae* and *Lithosiinae* from this formation alone, yet we consider their insertion here to be less inappropriate than the one preferred in other catalogue-works. Whilst STAUDINGER in his Catalogue (1871) places them quite correctly at the head of the „*Lithosiidae*“, REBEL (1910) places them next to the Cymatophorid *Axia margarita* and together with it between the Geometrids on the one hand and the Noctuid genus *Sarrothripus* on the other hand (!). DYAR, in his „List of North-American Lepidoptera“ scarcely more appropriately places them between the *Epiplemidae* and the strange Lacosomid *Cicinnus melsheimeri*, consequently near the *Psychidae*. We also range it in the American fauna before the *Lithosiinae*, after the *Syntomidae*, since they also exhibit relations to the *Arctiinae*. In KIRBY's Catalogue they are directly included in the *Lithosiidae*, which is well justifiable.

Nearly all the *Nolinae* are in their occurrence locally bound to certain slopes of mountains, clearings in forests and the like, and seem not easily to leave their birth-place. Nevertheless some are widely distributed; some species (*Cel. cicatricalis*, *centonalis* and others) extend from France to China or Japan, and *squalida* pro-

bably occurs in 4 continents in little modified geographical forms. As the young larvae frequently live on lichens — some even throughout their lives —, they are not so much bound to the growth of rich vegetation, and in entirely unwooded districts devoid of plants (Arizona, Central Mexico etc.) we meet yet with representatives of the *Nolidae*, just like we find in the nearly unwooded Egypt just as many *Nolidae* as we find in exuberant districts of Central Europe. In America the same is the case as in the Old World, i. e. in tracts of land of the size of Germany we may approximately find from half to a whole dozen of species of the *Nolidae*, so that the geographical distribution of the family is almost uniform on the whole globe; only in Costa Rica which, however, has been well explored, we find an accumulation of species. Otherwise it is quite immaterial whether one collects in the United States, Mexico, Colombia, Madagascar, Ceylon, Asia Minor, the Amur District, or in the Bavarian Palatinate; everywhere each well performed local collection will yield about 8 to 12 *Nolidae*. A remarkable fact is that America has not one species in common with the Old World.

1. Genus: **Nola** Lach.

On the whole very much like *Celama*, chiefly differing from it by the 4-branched subcostal, only the middle branch being absent, and by the upper radial vein rising at the upper cell-angle. The palpi are usually somewhat longer and project like snouts. In the American species the antennae of the ♂♂ are long-combed (Selca Wkr.)

maia. **N. maia** Schs. (32 k). Body and wings brown, mixed with grey; on the forewing there are two blackish transverse lines, the anterior one being distally bordered with yellow-reddish, the posterior one distally bordered with white; between both there are 2 dots at the cell-end; before the margin with a darker undulate line; hindwings whitish, dusted brown. Expanse of wings: 18 mm. Costa Rica.

niveibasis. **N. niveibasis** Jones (32 k) has a white body, the abdomen being dusted brownish, the forewings are white in the basal halves, distally red-brown; a black median line borders on the two colours and projects on the median towards the margin. At the base of the costal margin there is a blackish-brown spot, beyond the middle there is a dentate, black line distally bordered with white in a costal direction, and besides there is an indistinct, dark, antemarginal line. Hindwings whitish, dusted with red-brown. Expanse of wings: 20 mm. South Brazil.

mesocyma. **N. mesocyma** Dogn. (32 a) is a minute animal with white forewings with a red-brown tinge towards the distal and costal margins, with three fine, black median, postmedian and antemarginal transverse lines; at the upper cell-end there is a small accumulation of red-brown scales. Hindwings white, towards the margin brownish. Expanse of wings: 12 mm. French Guiana.

pulverea. **N. pulverea** Hmps. (32 l) is whitish on the body and wings, thickly dusted red-brown, with two transverse lines on the forewing, the posterior one of which is broken in an acute angle below the costal margin and in the lower half proximally dusted dark. Hindwings whitish, towards the margin brownish with a black middle dot. Expanse of wings: 20 to 26 mm. Bolivia.

sabulosa. **N. sabulosa** Schs. (32 a) is similar; the posterior transverse line is punctiform, more sharply dentate; in front of it at the costal margin a blackish spot and in the middle of the cell a small accumulation of black scales. Expanse of wings: 24 mm. Costa Rica.

mesographa. **N. mesographa** Schs. (32 a) is distinguished by a blackish-blue scaled costal-marginal spot in the middle, from which a brown and black band runs to the proximal margin; at the base of the costal margin there is a brown and black triangular spot, beyond the middle a transverse line of dots; before the border being dusted red-brown, a darker undulate line. Hindwings white, towards the margin brownish. Expanse of wings: 18 to 24 mm. Guiana to Brazil.

tripлага. **N. triplaga** Dogn. (32 a) is a tiny insect easily recognizable by the 3 dark costal-marginal spots; the middle spot is four-cornered with small heaps of black and silvery scales in the middle of the cell and at the upper end. Marginal area dusted red-brown. Expanse of wings: 14 mm. Panama.

caelata. **N. caelata** spec. nov. (32 a) is a small, very easily recognizable species. Head, thorax and forewings snow-white; at the costal base an oblong, red-brown spot, the centre is crossed by a broad, red-brown median band being broadest at the costal margin and somewhat strangulated on the submedian fold; on its proximal border there are, in a straight line above each other, 3 small heaps of thickly applied, enamel scales, of a black colour, with a green-silvery lustre, at the cell-end a fourth. Subterminal band of the usual shape, cloudy, red-brown; the border itself is likewise red-brown like the fringes. Hindwings light brownish-grey. Expanse of wings: 14 mm. — 1 ♂ from Orosi (Costa Rica) from the Coll. FASSL.

perluta. **N. perluta** spec. nov. (32 a). A tiny animal with mostly white forewings; only the marginal area is narrowly brownish; in front of it the 3 cloudy curves of the grey undulate line. In the middle of the costal

margin there is a brownish spot, behind which, indicated by black dots on the veins, the posterior transverse line runs, in some parts indistinctly double. Hindwings slightly smoky brownish. Expanse of wings: 15 mm. 1 ♂ from Muzo (Colombia) in the Coll. FASSL.

N. biconica *Hmps.* (32 a). Greyish-white, dusted brownish, with an antemedian and a median line, *biconica*, both of which proceed from triangular costal-marginal spots; a postmedian line of dots and an antemarginal undulate line. Expanse of wings: 12 to 16 mm. From Panama and Guiana to Brazil.

N. sperata *Schs.* (32 a) is strewn brown and black on the white forewings and traversed by ante-*sperata*. median and postmedian rows of black dots; at the base of the costal margin and in the middle there are triangular brown costal spots; at the base and below the cell-end black dots, before the border and close at it 2 rows of blackish-brown spots. Hindwings white, towards the margin brownish. Expanse of wings: 16 mm. Costa Rica.

N. artata *Schs.* (32 k) greatly resembles *biconica*, the head and thorax are of a purer greyish-white, *artata*. the forewings more silvery white, coarsely strewn with brown and black, the anterior transverse line only indicated by small darker scales. Hindwings of a darker brown. Expanse of wings: 16 mm. Costa Rica.

N. solvita *Schs.* (32 k) is grey, dusted brown and particularly in the basal part of an ochreous tint *solvita*. with 3 indistinct, finely dentate transverse lines and brownish shades in the middle and before the border being dusted darker brown. Hindwings greyish-brown. Expanse of wings: 20 mm. Brazil (Castro).

N. biumbata *Schs.* (32 k) is somewhat larger, thickly dusted reddish-brown and strewn with black; *biumbata*. on the forewings the median line and median shade are absent, the posterior transverse line is in the shape of a broad band and faded; the anterior line is connected with a dark cellular and costal-marginal spot. Hindwings brownish. Expanse of wings: 24 mm. Costa Rica.

N. apera *Drc.* (= *involuta* *Dyar*, *exposita* *Dyar*, *laguneulariae* *Dyar*) (32 a) is grey, dusted brownish, *apera*. and strewn with black on the forewings; costal margin dotted brown; anterior transverse line curved, quite indistinct, the posterior one broken up into dots; an antemarginal dark line with small black vein-stripes. Hindwings whitish, towards the margin brownish. Expanse of wings: 16 mm. Distributed from California to Bolivia and Peru. — Larva flattened, in the colouring varying from white to reddish, haired blackish with a double dark dorsal line and 2 undulate lateral lines; on the 2nd and 3rd rings there is a white spot, bordered subdorsally with black. It lives on willows.

N. bistriga *Mschlr.* (32 k) is very easily recognizable by the light creamy ground-colour, the forewings *bistriga*. being feebly strewn with red-brown; 2 straight red-brown transverse lines do not reach the costal margin; in front of the border there is besides an indistinct, curved line. Hindwing towards the apex brownish. Expanse of wings: 20 mm. Porto Rico.

2. Genus: **Nigetia** *Wkr.*

This genus, established for the only species known, differs from the comprehensive following genus preponderantly by the upper median and lower radial vein of the forewing being petioled; sometimes also the middle one is con-petioled. The palpi are erect, the second joint, owing to its dense sealing, almost quadrangular.

N. formosalis *Wkr.* (= *melanopa* *Z.*) (32 b). Head black; vertex, thorax, the 2 first abdominal segments, *formosalis*. and the forewings are white, the latter with a faint yellowish tinge and a black costal stripe and an oblique median band; an antemarginal band of a leaden colour, partly dusted brownish. Hindwings brownish-grey. Expanse of wings: 18 to 24 mm. United States, Carolina, Texas.

3. Genus: **Roeselia** *Hbn.*

In this genus, like in the preceding, all the subcostal veins are present; the upper radial vein of the forewing rises from below the upper cell-angle. The palpi are roughly sealed, mostly long, turned forward or downward, only in rare cases slightly upward; everything else like in *Celama* and *Nola*. Antennae of the ♂ in the American species doubly combed almost to the tips.

R. intermedia *Drc.* (32 e). Like in the following species the ♂ exhibits beneath in the cell of the forewing *intermedia*. an oblong excavation. White, faintly dusted brownish, with 3 almost quadrangular, black, dusted silvery costal-marginal spots and a similar dusting before the posterior transverse line between the cell and proximal margin; before the border being dusted with red-brown there is an undulate line. Hindwings white, dusted brownish-grey towards the margin. Expanse of wings: 22 mm. Costa Rica.

R. pernitens *Schs.* exhibits on the silvery white forewing, beside the costal-marginal spots, only one *pernitens*. line in front of the margin being dusted brown below the apex. Hindwings white, towards the margin brownish. Expanse of wings: 16 mm. Costa Rica.

- biconigera*. **R. biconigera** *spec. nov.* (32 c) shows in the ♂ beneath on the forewing a deep, circular excavation in the cell on the border between the middle and distal third. Head, thorax and forewings white, strewn with silvery grey. Collar with a brownish band. The forewing shows at the base and middle of the costal margin one blackish-brown, triangular spot each; of the other marking there is mostly little to be noticed; in a distinctly marked ♂ there is a curved antemedian and a feebly dentate posterior transverse line which, as usually, encircles the cell in a bow; in the lower half, at its proximal side, there runs a sharply dentated line; the apical third of the white costal margin with 3 small black spots. Marginal area and undulate line grey-brownish. Hindwings light grey. Expanse of wings: 15 to 17 mm. Type from Espiritu Santo in the Coll. DRAUDT; besides from Costa Rica, Colombia (FASSL).
- placens*. **R. placens** *Schs.* (32 c). The silvery-white forewings are in the costal halves and close in front of the margin dusted red-brown, and exhibit postmedian and antemarginal transverse lines of a leaden colour; in and below the cell-end there is a red-brown scale-spot, above it a triangular costal-marginal spot. Hindwings brown. Expanse of wings: 18 mm. Costa Rica.
- deglypta*. **R. deglypta** *spec. nov.* (32 c) differs from *placens* by the greater extent of the red-brown dusting of the costal margin, so that only the proximal-marginal part below the submedian fold remains purely white; behind the cell the brown costal area is bordered by a broad, olive-grey crescentiform or reniform band, likewise extending to the submedian fold. Marginal part of the costal margin greyish-white with 4 small black costal spots; apex cut off by an oblique white band. Border otherwise dusted red-brown; the cloudy grey undulate line projects in the middle roundish towards the margin; as the lower border of the white marginal streak it extends in a pointed tooth close to the margin. Hindwings brownish. Expanse of wings: 19 mm. 1 ♀ from the Songo (Bolivia) in the Coll. FASSL.
- leucogramma*. **R. leucogramma** *Dogn.* exhibits in the female an oblong excavation below the upper subcostal vein. Forewings white, dusted reddish ochreous, and strewn with black as far as in front of the border; black antemedian and postmedian transverse lines being on the averted sides bordered with white, between them a faded median line, and before the margin an undulate line being distally bordered with white. In the cell before and in the middle small heaps of black and ochreous-yellow scales. Hindwings white, towards the margin yellow-brownish. Expanse of wings: 24 mm. French Guiana.
- bifiliferata*. **R. bifiliferata** *Wkr.* (= *terulosa* *Drc.*) (32 c) is a widely distributed and common species, recognizable by the silvery grey forewings exhibiting the costal margin dusted with a rusty colour and the double anterior transverse line turning at the proximal margin back almost as far as the base; the posterior transverse line is double, too; in front of it there is another dentate, black line; between it and the marginal line there are black vein-streaks. Head and collar are rusty brown. Extremely variable in size. Expanse of wings: 15 to 27 mm. From Mexico, Costa Rica, Panama, Colombia and Brazil.
- polyodonta*. **R. polyodonta** *Schs.* (32 c) greatly resembles the preceding, but it has a white head and collar; the forewings are white, uniformly dusted and the median line is much longer, almost digitiformly dentated; the antemarginal line touches the margin at 3 places. Fringes speckled black and white. Hindwings white, at the margin brownish-grey. Expanse of wings: 20 to 22 mm. From Mexico to French Guiana.
- micans*. **R. micans** *Hmps.* (= *fasciata* *Rothsch.*) (32 c) is silvery white, scantily strewn with black, with a triangular black spot at the base and a square one in the middle of the costal margin. The transverse lines indistinct; an undulate antemarginal line. Expanse of wings: 18 to 24 mm. Colombia. Bolivia.
- canescens*. **R. canescens** *spec. nov.* (32 d) resembles *micans*, with a little broader and rounder wings; the ground-colour of the forewings is a delicate bluish-grey, scantily strewn with brown, the marking quite similar, all the transverse lines more distantly remote, the costal spot triangular; the small heap of scales is not situate in it, as in *micans*, but below its apex. Hindwings brownish-grey. Expanse of wings: 22 mm. 1 ♀ from Orosi (Costa Rica) in the Coll. FASSL.
- argyraspis*. **R. argyraspis** *spec. nov.* (32 d) is a tiny, silvery-white insect; the forewings are tinged greyish-brownish towards the margin, and exhibit at the base and middle of the costal margin one blackish-brown, triangular spot each like in the preceding; the scaly spot strewn with silvery scales and touching the apex of the triangular spot, in the middle of the cell, is very large, round, jet-black, and exhibits silvery scales, being arranged concentrically to its margin, so that the impression of a ring is created; the indistinct postmedian line encircling the cell grows thicker below the submedian fold and form a V with the thick black median line touching it at the proximal margin. Costal margin spotted black; undulate line of the usual shape, smoky grey. Hindwings towards the margin with a faint brownish hue. Expanse of wings: 12 mm. 1 ♂ from the Upper Rio Negro (East Colombia) in the Coll. FASSL.
- unilinea*. **R. unilinea** *Schs.* (32 c) is a small species very easily recognizable by the blackish-brown postmedian band; the forewings are otherwise silvery white, at the margin dusted brown, with an undulate antemarginal line and a dark spot at the base of the costal margin. Expanse of wings: 16 mm. Costa Rica.

R. trocha Dogn. (32 d) is a little similar, though much larger and with a much broader median band; *trocha*. near the apex of the forewing there is yet a large, triangular costal-marginal spot. Hindwing brownish-grey. Expanse of wings: 24 mm. Ecuador.

R. leucostola Hmps. (= *melicerta* Drc. p. p.) (32 d) has on the white forewing only one large, quadrangular costal-marginal spot in the middle, one small spot each at the base and subapically at the costal margin, an interrupted nebulous antemarginal line with 3 projectures towards the margin, the middle one of which forms a large marginal spot. Expanse of wings: 26 mm. Costa Rica.

R. rufescens Dogn. (32 d) is white on the forewings, densely dusted red-brown, except the basal half of the proximal margin, a spot in the cell-end and two spots at the apex and proximal angle; the transverse lines are indistinct, the veins behind the cell striped black; instead of the undulate line there is only an oblique streak below the apex. Hindwings purely white. Expanse of wings: 26 mm. Ecuador.

R. causta Hmps. (32 l) is very similar, the whole wing more densely dusted red-brown, and with a distinct, bluish-grey undulate line; behind the median line there is a double transverse line; the space between the latter and the undulate line remains white. Hindwings white, towards the margin brownish. Expanse of wings: 20 mm. Bolivia.

R. niveicosta Schs. (32 d) is still more densely dusted red-brown, but the costal margin remains here broadly whitish; below it the dusting is still darker; the 3 transverse lines are only indistinctly marked by the light ground-colour. Expanse of wings: 22 mm. Brazil (Castro, Paraná).

R. versicolora Dogn. (32 e) is a large species with white forewings dusted grey and red-brown and strewn with black, with black antemedian and postmedian transverse lines, the latter of which is distally bordered with white; a similar undulate line is before the border, in front of it black sagittiform spots; in the median area at the costal margin a triangular spot with black dusting below it, and at the cell-end 2 small heaps of black scales with a whitish crescent behind them. Expanse of wings: 20 to 28 mm. Peru, Colombia. The posterior transverse line may also consist of larger black cuneiform spots (= ab. 1 Hmps.). In another form: **rufofusa** nom. nov. (= ab. 2 Hmps.), the wing is intensely suffused with red-brown, and the veins are striped black beyond the distal transverse line.

R. effusa spec. nov. (32 e) is still larger than the preceding, much more slenderly built; forewings more pointed with a more oblique margin. The scaling is smoother and more lustrous, much less strewn with white. The marginal area exhibits only the clouded undulate line, the small, black sagittiform spots before it are absent; in the median area we see a kind of a blackish-brown median band. Hindwings snow-white, fringes very long. Expanse of wings: 30 mm. 1 ♂ from the Quindiu Pass in the Coll. FASSL.

R. hermana Schs. (32 l) has in the basal half of the costal margin a long, red-brown spot; the anterior and posterior transverse lines are double; the veins behind the latter, as well as the median are black, before the margin connected by an indistinct, dentate line. Hindwings whitish, towards the margin brownish, in the ♀ quite dark. Expanse of wings: 20 to 24 mm. Mexico, Brazil.

R. mediozona Dogn. (32 d) is white, strewn with brown and grey, with a very broad, brown median band bordered with black, in it a whitish spot in the cell-end, and at the costal margin 3 black dots; the veins in the marginal half marked blackish with a fine, dentate line behind them. Hindwings of a pure white. Expanse of wings: 28 mm. Ecuador.

R. perangulata Hmps. (32 d) is a large, easily recognizable species looking very much like the following. The forewing is of a purer white, only at the costal margin dusted brown, the posterior transverse line is pointedly broken on the lower radial vein; a brown macular band is before the margin, in the space between black vein-streaks. Hindwings lighter. Expanse of wings: 32 mm. Bolivia, Peru, Brazil.

R. pedanta Dyar (32 e) is very similar, the forewing more uniformly dusted brownish-grey; the posterior transverse line is pointedly broken on the lower median vein, a black median line is inwardly angled on the two median veins, before the margin there is a black, dentate, undulate line, behind it below the apex red-brown dusting. Hindwings darker brownish grey. Expanse of wings: 30 mm. Mexico, Costa Rica.

R. recurvata Dogn. (32 e) is likewise somewhat similarly marked, dusted much darker and more densely brown and strewn with black, the transverse lines less sharply broken and less strongly curved, on the averted sides bordered with whitish. Expanse of wings: 30 mm. Colombia.

R. pygmaea Hmps. (32 e) is smaller, with white forewings strewn with brown, the marking very much like in *pedanta*, with small heaps of leaden-lustrous, blackish-brown scales in the middle of the cell and at the end; in the middle of the costal margin there is a small, dark triangular spot; in the indistinct undulate line before the margin there are black vein-streaks. Expanse of wings: 16 to 23 mm. Brazil (São Paulo, Castro Paraná), Colombia (Tolima, Rio Negro).

- dentata*. **R. dentata** Dyar (32 l) is a greyish-brown species with a finely dentated anterior, and strongly dentated posterior transverse line and a round dark spot in and below the middle of the cell; undulate line indistinctly darker. Expanse of wings: 24 mm. Arizona.
- antennata*. **R. antennata** Btlr. (= *snelleni* Btlr. ♀) (32 l) is very similar, much lighter, more yellowish-brown, the posterior transverse line is not dentate, but inwardly a dentate line runs parallel to it. Hindwings white, towards the margin brownish. Expanse of wings: 18 mm. Amazon.
- divisa*. **R. divisa** Schs. (32 k). The forewings are in the basal half white, at the costal margin dusted brown and black, in the distal half grey, strewn with black, with a white apical spot; the anterior transverse line is indistinct, the posterior one broken up into dots, inwardly dusted darker blackish-brown; an ante-marginal, irregular undulate line; large heaps of scales are situate in the cell near the base, in the middle and at the end of it. Hindwings whitish, towards the margin brownish. — In *natama* Schs. the marginal area is much darker brown, strewn with black and white, in **fusca** *nom. nov.* (= ab. 2 *Hmps.*) the whole thorax and forewing are unicolorously covered with brown. Expanse of wings: 20 mm. Brazil.
- divisoides*. **R. divisoides** Schs. (32 k) is a very similar animal; the forewings are more uniformly white, at the costal margin and in the marginal area less dusted brown with more distinct transverse lines, the anterior one being distinctly dentate; the dentate median line more indistinct. Fringes speckled white and brown. Hindwings more uniformly brownish-grey. Expanse of wings: 18 to 22 mm. From French Guiana and Brazil (Rio de Janeiro, Santos).
- arana*. **R. arana** Schs. (32 f) is light brown, on the vertex white, on the thorax and the costa of the forewing at the base and before the apex strewn with greenish-black scales; in the middle of the cell and at the end there are large heaps of yellowish scales. Transverse lines distinct only near the costal margin, farther below dying away or broken up into dots, the posterior one double. Apex of the wing spotted white. Expanse of wings: 24 mm. Brazil.
- patina*. **R. patina** Drc. (32 e). Forewings brownish-grey, strewn darker, with black costal-marginal spots near the base and at the upper cell-end, the latter triangular, on it and in the middle of the cell there are large heaps of black scales; the posterior transverse line is broken up into dots, and before it there is a dentate transverse line; undulate line indistinctly dentate, behind it black marginal dots. Hindwings brownish-grey. Expanse of wings: 20 to 30 mm. Costa Rica.
- plumatella*. **R. plumatella** Drc. is very similar, distinguished by its larger size and lighter hindwings. Expanse of wings: 30 mm. Guatemala.
- rodea*. **R. rodea** Schs. (32 e) is likewise similar; forewings white, dusted brownish-grey, marked almost the same; the middle costal-marginal spot, however, is square and not so deep blackish-brown; the scaled spot in the middle of the cell is removed more to the end. Hindwings white, towards the margin brownish or quite greyish-brown. — **garuba** Schs. is of a purer white, scarcely dusted darker. Expanse of wings: 18 to 22 mm. Brazil (São Paulo; Castro; Paraná).
- flaviscapula*. **R. flaviscapula** *spec. nov.* (32 f) belongs to the same group. Head and thorax white, shoulder-covers ochreous-yellow. The white forewings are densely dusted light brown; the scheme of markings is the same as in the preceding species, but the sharply dentate transverse lines are much less distinct, their course almost only indicated by long, black vein-streaks. Very characteristic are the 3 small heaps of scales at the base, the middle and end of the cell: blackish-brown, towards the margin broadly ochreous-yellow. Hindwings light grey, towards the margin smoky brownish. Expanse of wings: 22 mm. 1 ♂ from Pacho (Colombia) in the Coll. FASSL.
- minuscule*. **R. minuscule** Z. (= *phylla* Dyar, *minor* Dyar, *patina* Drc. part.) (32 f) differs by the longer, more stretched shape of the wings, the markings otherwise very much like the preceding. The wings are dusted darker brown and densely strewn with black; instead of the basal costal-marginal spot there are only two small dots. Hindwings brownish-grey. — **fuscula** Grt. (= *conspicua* Dyar) is a larger and still darker brown form. — **postalbida** *form. nov.* (= subsp. 1 *Hmps.*) may be called a form from Bolivia with entirely white hindwings being brownish only at the apex. The species is otherwise widely distributed in North America (Texas, Colorado, California, Arizona), Mexico and Panama as far as Colombia. Expanse of wings: 24 to 30 mm. — The larva living on different oaks, is cream-coloured on the dorsum, beneath lighter with dark brown subdorsal bands, which are connected by transverse bands on the rings 7 and 11; it is light-haired, on the 3rd ring very long and pupates in a cymbiform web covered by bark.
- punctilinea*. **R. punctilinea** *spec. nov.* (32 f) is another species approximating *patina*. Forewings of a much purer white, only very scantily strewn with black. Marking the same, but all the transverse lines are on the veins thickly dotted black; the parallel line accompanying the posterior transverse line inside, is very much approached and forms on the inner-marginal vein a pointed tooth directed towards the base. Fringes of a yellowish lustre, in the basal half speckled brownish-grey. The white collar exhibits a blackish-brown transverse band. Hindwings brownish-grey. Expanse of wings: 26 mm. 1 ♀ from Orosi (Costa Rica) in the Coll. FASSL.
- stilbina*. **R. stilbina** *spec. nov.* (32 f) is of a purer grey than *minuscule* with entirely white hindwings, with a fine, dark marginal line; very characteristic are the two thick, black transverse lines: the anterior one almost

straight, only below the costal margin feebly curved, the posterior one encircles, almost in the shape of a quadrangle, the crescentiform, white cell-end macula, projecting the farthest towards the margin on the lower radial vein. The small heaps of scales of a blue lustre. Expanse of wings: 25 mm. Several ♂♂ from Pacho (Colombia) in the Coll. FASSL.

R. stictigrama Dogn. (32 f). Forewings white, dusted with a reddish ochreous yellow and strewn with black; an anterior row of black dots doubles towards the proximal margin; above the cell-end there is a black spot at the costal margin, as well as at the base; behind the cell there are besides 2 double rows of dots, and before the margin a third. The white hindwings, being brownish towards the costal margin, likewise exhibit a postmedian row of black vein-dots. Expanse of wings: 26 mm. Colombia. *stictigrama*.

R. nepheloleuca Hmps. (32 g) is very similar; on the forewings the space below the cell, in the cell-end and behind it remains purely white; the posterior transverse line is white, only at the proximal side marked by black dots; before the margin white streaks. Hindwings white, towards the margin brownish. Expanse of wings: 24 mm. Venezuela to Peru. *nepheloleuca*.

R. semicrema spec. nov. (32 g) greatly approximates the preceding, different by more intense cinnamon-coloured dusting along the whole costal margin and in the marginal area; the whole surface of the wings, moreover, is strewn with rusty brown scales; only the apex of the wings remains light whitish; marking otherwise similar, the black subterminal spots thicker. Hindwings dark brownish-grey. Expanse of wings: 19 to 24 mm. A number of specimens in both sexes from Colombia and Bolivia. — A ♂ from Bolivia I for the present consider to be a form of this species: **apiciplaga** form. nov. (32 g). The cinnamon colour is here confined to a large subapical spot, the costal margin remains more extensively white, the marking is finer; everything else is the same. *semicrema*, *apiciplaga*.

R. pulverea Dogn. (32 f) is a very large species of a slender structure, on the white forewings dusted yellowish-brown and strewn with black; anterior transverse line double, in the cell behind it a small heap of dark scales; in the middle of the costal margin a dark spot with 2 black dots and two below it; the posterior transverse line consists of minute, fine black teeth; undulate line faded dark; fringes speckled. Expanse of wings: 34 mm. Colombia. *pulverea*.

R. metaleuca Hmps. (32 g) on the greyish-brown forewings, exhibits white dusting at the costal margin, in it 2 velvety black spots at the base and in the middle; the posterior transverse line is broken up into dots. Hindwings of a pure white with a small median dot and a line beyond it, in the ♀ dark brownish-grey. Expanse of wings: 24 mm. Costa Rica, Colombia, Bolivia. *metaleuca*.

R. godalma sp. nov. (32 g). This greatly distinguished species resembles *metaleuca*. The ground of the wings is quite purely lustrous olive-brownish; all the black dusting or spots are absent except the two large, jet-black costal-marginal spots; costal margin and transverse lines purely snow-white, hindwings white with a brownish discal spot and margin. Expanse of wings: 22 mm. 1 pure ♂ from the Quindiu Pass (3500 m) in the Coll. FASSL. *godalma*.

R. decepta Schs. (32 g) is much smaller and more purely white, strewn with a dark brown, towards the margin darker brown, the other marking entirely like in *godalma*. Expanse of wings: ♂ 12 mm, ♀ 18 mm. Costa Rica. *decepta*.

R. medioscripta Schs. (32 h) is grey with a long, black costal-marginal spot at the base and a broad, slightly bent black median line which proceeds from a triangular costal-marginal spot; anterior transverse line very indistinct, the posterior one broken up into dots. Expanse of wings: 22 mm. Mexico (Orizaba, Jalapa), Costa Rica, Colombia (Quindiu), Bolivia (Rio Songo). — In a specimen from the Quindiu from the Coll. FASSL: **basifusca** form. nov. (32 h) the whole basal area as far as the median line is coloured dark brown. *medioscripta*, *basifusca*.

R. excelsior spec. nov. (32 g) is a magnificent species resembling *basifusca* in the scheme of markings. Head silvery white, thorax yellow mixed with cinnamon-brown. Basal half of the forewing lustrous straw-coloured, at the costal margin brownish and defined from the silvery white marginal area by 2 red-brown, uniformly rounded parallel lines. The marginal area is traversed by a double, sharply dentated black postmedian, the two lines of which are twice as far remote from each other below the 2nd median vein, as they are above it; the very pointedly dentated subterminal band extends almost to the slightly brownish marginal area, in which there is besides a very regular dentate line close in front of the brown fringes parted by a white line. Hindwings white, towards the margin behind the faint postmedian line tinged grey. Expanse of wings: 21 mm. Some specimens from Colombia (Cañon del Tolima) in the Coll. FASSL. *excelsior*.

4. Genus: **Celama** Wkr.

More than a dozen members of this genus being distributed in the whole world, have hitherto become known to us from America. As to the diagnose we refer to Vol. II. We simply state here, that the species are distinguished from the other genera by the subcostal being only 3-branched, only the uppermost branch and the two lower ones being present. The uppermost radial vein comes from below the upper cell-angle.

- carilla.* **C. carilla** Schs. (32 k) is a tiny, greyish-white animal, mixed with brown on the thorax; on the forewings, with a brown base of the costal margin and a triangular spot in the middle of the costal margin, there are antemedian and postmedian transverse lines, the latter composed of dots; below the middle costal-marginal spot a scaled spot at the cell-end which is continued to the proximal margin, below the lower median vein as a line parallel to the posterior transverse stripe; before the margin and on it one brown line each. Hindwings white, dusted darker. — The median area may be darkened in the shape of a band: f. **mediofasciata** nov. (32 b) (FASSL, Orosi). Expanse of wings: 12 to 18 mm. Costa Rica.
- scruposa.* **C. scruposa** spec. nov. (32 b) resembles the preceding, but it has somewhat narrower wings, and is much more coarsely scaled, chalky white, thickly strewn with black scales; the median area darker by blackish-brown scales in the shape of a band, the scheme of markings otherwise just like in *carilla*; in the cloudy undulate line and before the fringes there are distinct black vein-streaks. Hindwings lighter. Expanse of wings: 18 mm. 1 ♀ from Orosi, Costa Rica; type in the Coll. FASSL.
- aphyla.* **C. aphyla** Hmps. (32 l) shows on the grey forewing strewn with black 2 dentate transverse lines being sharply broken in an acute angle; besides an irregularly dentate, antemarginal line. Hindwings white, towards the margin darkened. Expanse of wings: 22 mm. California.
- semirufa.* **C. semirufa** Dogn. (32 b) is easily recognizable by the forewing being white in the smaller basal half and distally red-brown; in the middle of the cell a small heap of black and silvery scales, beyond the middle black vein-dots and small, white, costal-marginal dashes. In contrast with the following, the border between white and brown is a straight line. Expanse of wings: 16 mm. Colombia.
- dimera.* **C. dimera** Dogn. (32 b) differs from the preceding, very similar species by the bent black line separating the white area of the wing from the brown one; a postmedian, undulate, black line and, besides, 2 somewhat more indistinct, antemarginal lines. Expanse of wings: 16 mm. French Guiana.
- Sect. II. Antennae of the ♂ with ciliary tufts (*Aradrapha*).
- pustulata.* **C. pustulata** Wkr. (= nigrofasciata Z., obaurata Morr.) (32 b) is white; forewings with heaps of black scales at the base of the cell, as well as in and behind the cell-end; at the base of the costal margin there is a brown spot strewn with black; a similar, almost triangular median band is distally bordered by the punctiform postmedian line; before the margin an irregularly dentate line and on the margin a dark macular band. The white hindwings are brownish towards the margin. Expanse of wings: 22 mm. Northern Atlantic States.
- cilicoides.* **C. cilicoides** Grt. (32 k) differs from the preceding by the median band being placed much more towards the margin and being tinted only quite pale brown. A small heap of blackish-brown scales with a leaden-lustrous admixture. Expanse of wings: 18 mm. Atlantic States.
- appelia.* **C. appelia** Hmps. (32 k) is likewise somewhat similar, in the basal half dusted brownish with accumulations of brown scales in the base, middle and end of the cell; before the middle a brownish transverse line; the brown dusting before the postmedian is much less sharply defined. Expanse of wings: 20 mm. Brazil (São Paulo).
- sorghiella.* **C. sorghiella** Riley (= portoricensis Mschlr.). Forewings purely white with a brown base of the costal margin; small heaps of scales as in *appelia*; the brown dusting before the posterior transverse line is absent, only beyond the lower cell-angle it is exhibited in the way of spots; in the lower marginal half there is an undulate line. Expanse of wings: 16 mm. Most widely distributed from North Carolina through Dutch Guiana as far as Argentina. — The larva is yellow or greenish with a brimstone-coloured dorsal stripe bordered on both sides by brown, and stiff hairs on tubercles; in the sides there are somewhat longer hair. It lives in a web on *Sorghum vulgare* and turns into a yellow-brownish, darker granulated pupa.
- triquetrana.* **C. triquetrana** Fitch. (= trinotata Wkr., sexmaculata Grt.) (32 b) is grey, densely dusted brown, on the collar with a red-yellow band and brown spots on the shoulders. The forewings exhibit at the costal margin 3 red-brown spots, the two posterior ones of which exhibit small heaps of scales at their lower ends; 3 oblique, partly dentate transverse lines cross the wing. Hindwings whitish, towards the margin brownish with a small median dot. Expanse of wings: 20 mm. North America, California. — Larva light yellow with blackish dorsal and subdorsal lines and white hairs on tubercles. It only eats the upper epidermis of the leaves of *Hamamelis virginica* and pupates in a scaphoid casing with small pieces of bark pasted on it.
- minna.* **C. minna** Bllr. (= hyemalis Stretch.) (32 a). White, strewn with brown; before and behind the middle there are oblique rows of dots, before the margin an irregularly undulate line; at the base of the costal margin with a red-brown, oblong spot. Expanse of wings: 26 mm. California.
- ovilla.* **C. ovilla** Grt. (32 b) is an insignificant, greyish-brown, darker strewn, small animal with indistinct, partly punctiform transverse lines and small heaps of scales at the base, middle, and end of the cell. Hindwings

white, brownish towards the margin; abdomen yellowish. Expanse of wings: 20 mm. Atlantic States. — The dark-haired larva lives on oak and pupates in a scaphoid web on the upperside of a leaf.

C. clethrae Dyar (32 l) differs from the very similar preceding species by its more bluish-grey, *clethrae*. not brownish colouring, and somewhat more distinct marking. Hindwings darker. Expanse of wings: 20 mm. New York. The diaphanous white larva with irregular, grey dorsal and lateral stripes lives on *Clethra atrifolia* and pupates in a triangular web covered with bark.

C. albirufa Schs. (32 b). Forewings white, strewn brownish, and at the costal margin and border dusted *albirufa*. red-brown, traversed by 2 very oblique lines broken up into dots; from the lower cell-angle a red-brown median shade runs to the proximal margin. Expanse of wings: 14 mm. French Guiana.

C. obliquata B. & McD. Dull grey; forewing with a straight, blackish-brown antemedian line and a *obliquata*. similar posterior transverse line slightly curved round the cell-end, with dark vein-dots; before the margin there is a lighter undulate line, on the border black dots. Hindwings brownish-grey, towards the base lighter. Expanse of wings: 16 mm. Florida.

II. Lithosiinae.

About 600 forms of this subfamily are known to us from America; like most of the palearctic *Lithosia*, they are mostly rather insignificant forms, being besides very rare. Whoever is not well acquainted with their life-history, may collect carefully in America without meeting with a single more conspicuous *Lithosiina*. Whilst in Europe particularly *Oeonistis quadra* and some small *Lithosia* in the plains, *Endrosa* in the alpine districts, are met with in greater numbers, in Eastern Asia especially the *Stigmatophora*, in the East Indies mostly species from the genera *Chionaema* and *Mitochrista*, in Australia *Eutane* and certain *Asura* resembling them exteriorly, and whilst in New Guinea and the Moluccas the hemochrome *Chionaema* of the *fulvia*-(*liboria*)-group belong to the characteristic insects: there occur in America chiefly blackish-yellow forms exhibiting the very same orange bands as a very great number of butterflies of other families (genuine *Arctiinae*, *Geometridae*, *Dioptriidae*, *Syntomidae* etc.) do; they are lively, often diurnal, small insects resting on blossoms, but they must sometimes be also beaten out of the bushes and may even come to the lamp in the evening; as, for instance, the genus *Josiodes* with nearly 30 American forms, many *Agylla*, the *Euryptidia*, *Cisthene* etc.

Of the American *Lithosiinae* scarcely 30 forms occur in the nearctic region; the whole rest is tropical or subtropical. It is surprising how rapidly the *Lithosiinae* decrease if one proceeds from the tropics towards the towards the polar region. Close at the tropical frontier (for instance near Rio de Janeiro) *Lithosia* may be taken by the lamp every evening, but a few degrees of latitude more to the south they disappear altogether, whereas in the equatorial districts they had almost become troublesome to us. In the tropics the glass of the lamp is sometimes covered with the snow-white *Agylla*-species marked with a dark inner-marginal stripe, of which we meet with but very rare examples in the south, and which are entirely absent in the United States.

Like in the palearctic *Lithosiinae*, the greater number of the 108 American genera (i. e. 66) are monotypical or they at most have two, often very similar forms. The reasons why the *Lithosia* are so very difficult to comprise by morphological criteria, we have mentioned in Vol. X, p. 118, where we stated the fact that in the Indian fauna the inclination applicable for the whole subfamily of separating an uncommonly great part of the species also with respect to the genus, is distinctly exhibited. About 150 genera have been established for the Indian *Lithosiinae* numbering about 1000 forms, so that, on an average, only 7 to 8 forms fall to each genus. About the same proportion is found in the American forms, about 600, with more than 100 genera. We may infer therefrom that the *Lithosia*-species have been more extensively specialized than most of the other groups of butterflies, and that the judgment of the value of their generic characteristics has not yet found the right criteria for their systematization. As we have already elsewhere pointed out, the venation appears to be often influenced by scent-spots or other, evidently secondary formations, so that the deviations of the veins may not be considered to be of the phylogenetic importance it usually has in other groups. The names of the genera *Paraggylla*, *Neaggylla*, *Paratalara*, *Epitalara*, *Neothyone*, *Paramulona*, *Neomulona* etc. already show that their mostly single species do not deviate too far from the *Talara*, *Mulona*, *Thyone* etc.

This explains also why the few genera counting more than a dozen forms mostly comprise an uncommonly large number of species, the *Afrida* with 30, the *Illice* with almost 60, the *Agylla* even with 76 exclusively American forms.

As to the characterization of the subfamily vide Vol. II, p. 50; in Vol. X, p. 118 to 120, it is supplemented. To the biological statements made there we may add yet, that in the American fauna we find the

colouring and marking of the *Lithosiinae* to be far more similar to that of other groups, than we find it in Europe, Asia or Australia.

About the early stages of American *Lithosiinae* we as yet know very little; but just this ignorance makes us presume that they behave like their palearctic allies, feeding on lichens and keeping hidden on trunks and in fissures of stones.

The frailty and delicate bodily condition of nearly all the *Lithosiidae* prevents them from being able to fly across big oceans. Thus America has not one single *Lithosia* in common with the other continents, and among the 250 genera there are even only few that have representatives on both hemispheres.

Also with respect to the imagines our knowledge of the American *Lithosiinae* is very deficient; nearly half of all the species known have been only published in the two last decades, and this gives us an idea of the great number of forms unknown to us, which may yet be discovered in the vast forests of South America. The *Lithosiinae* are mostly not common, often even very rare and besides lead a very obscure life. The larvae very rarely appear; owing to their insignificant exterior and their feeding from lichens nobody has yet been induced to breed them on a large scale. Nor are they easy to handle in the collections; their delicacy and mostly very brittle scaling make their preservation and preparation very bothersome. Their scientific operation likewise offers great difficulties already stated above by the fact that a very great part of the species could not be combined to one genus with another species. It is G. HAMPSON's desert to have completed and rendered more scientific the Catalogue of the American *Lithosiinae* which has been very incomplete at KIRBY's times — by his fundamental „Lepidoptera Phalaenae of the British Museum“. We therefore follow this commendable work, though in about the reverse order, so as to agree with the treatises of the same groups in the Indo-Australian (Vol. X) and palearctic (Vol. II) faunae, which are arranged according to the Catalogue of Staudinger-Rebel. Numerous figures of species, of which only one specimen has become known, have been copied from HAMPSON's work.

1. Genus: **Chrysozana** Hmps.

Proboscis well developed; the short palpi porrect; shaft of antenna somewhat thickened, in the ♂ covered with ciliary pencils. On the forewing the upper median vein proceeds from below the cell-corner, from which the lower radial vein originates; the two upper ones rise in common from the middle of the transverse vein; the second lowest subcostal vein is absent, the uppermost anastomoses with the costal. Veins on the hindwing greatly simplified: the upper median and lower radial vein coincide, the middle radial is absent altogether, the upper radial is petioled with the subcostal. The whole distal half of the hindwing is beneath in the ♂ covered with rough scent-scales. The genus contains only 1 small species.

croesus. **C. croesus** Hmps. (33 g) is golden on the thorax and forewing, with a black margin; hindwings carmine with a black marginal band; abdomen orange, above red, in the ♀ with a black apex. Expanse of wings: 20 mm. Bolivia.

2. Genus: **Boenasa** Wkr.

It contains only one most peculiar, small animal, the hindwing being stunted to a small triangular rudiment hidden below the base of the proximal margin of the forewing; instead of it the whole inner-marginal part is so very much developed that it assumes — without veins — the function of a normally sized hindwing; the latter, for this purpose, is turned over in such a way that the original under surface becomes the upper surface, so that its proximal margin has become the functional costal margin. The forewing is otherwise like in the preceding genus, though the two upper radial veins are separated; the lowest subcostal vein rises yet below the cell-angle, the two next ones are petioled. The palpi are longer and more slender than in *Chrysozana*.

nigrorosea. **B. nigrorosea** Wkr. (33 f). Anterior body and forewing blackish-brown with an oblique red antemarginal band, a red discal spot and small stripes at the base of the proximal margin. Abdomen and hindwings red, the latter with dark fringes. Expanse of wings: 26 mm. Hayti.

3. Genus: **Metallosia** Hmps.

Similar as *Chrysozana*, but with long-haired posterior tibiae and two first joints of the tarsi. The proximal angle of the hindwing is extended to a lobe, and long and thickly haired.

chrysotis. **M. chrysotis** Hmps. (33 f) is golden on the anterior body, with a bronze-green head, collar and shoulder-covers. Abdomen red with a brown anal tuft and orange lateral tufts. Forewings brown, with golden scales; hindwings carmine with a black apical spot and orange inner-angular fringes. Expanse of wings: 16 mm. Brazil.

nitens. **M. nitens** Schs. is brown on its body and forewings, suffused with a metallic green, the hindwings being unicolorously brown. Expanse of wings: 20 mm. Costa Rica.

4. Genus: **Deua** Wkr.

On the forewings also like the preceding genera. Veins of the hindwings extremely simplified by the absence of the upper median and middle radial, and by the upper radial anastomosing with the subcostal vein. Only 1 species:

D. imbutana Wkr. (34 a) is coppery brown; the forewing exhibits a blackish cell-spot in an elliptic, *imbutana*. yellowish-grey spot extending as far as the proximal angle. Expanse of wings: 14 mm. Brazil.

5. Genus: **Bruceia** Neum.

Proboscis stunted, palpi short, erect, forehead with a round projection, antennae finely serrate. Abdomen roughly haired. Veins like in *imbutana*, but on the forewing the upper radial vein rises from below the upper cell-angle, on the hindwing the upper radial vein rises on a long pedicle together with the subcostal. Only 1 species:

B. pulverina Neum. (= *hubbardi* Dyar) (33 g) is grey, with an ochreous-yellow tint and strewn *pulverina*. with black. On the forewings there are median and antemarginal, indistinct transverse lines of a lighter ground-colour, being inwardly tinged darker, a small, lighter discal spot between. Hindwings lighter. Expanse of wings: 24 to 36 mm. Colorado, Arizona.

6. Genus: **Haematomis** Hmps.

Very much like the preceding; on the forewing the two lower radial veins rise with the upper median vein from the same place; the uppermost subcostal vein anastomoses with the costal, all the rest as in *Bruceia*.

H. mexicana Drc. (33 g). Head and metathorax light yellow, shoulder-covers rosy, body otherwise *mexicana*. blackish-brownish. Forewings more grey with yellow longitudinal stripes. Hindwings light yellow, in the ♀ brownish-grey with a light yellow longitudinal stripe. Expanse of wings: 22 to 24 mm. Widely distributed and common in Arizona, Mexico, Guatemala.

H. radians Dyar (33 g) is very similar, of a somewhat broader shape of the wings with finer longitudinal *radians*. stripes on a darker, more reddish-brown ground. Hindwing whitish, dusted brown, with a whitish longitudinal stripe. In the ♀ the light stripes are entirely absent on the submedian fold and proximal margin, the hindwings being one-coloured brownish-grey; anal tuft rosy, so is a spot on the metathorax. Expanse of wings: 20 mm. Mexico (Orizaba, Guerrero).

H. uniformis Schs. (33 g) differs by one-coloured greyish-brown forewings, only the costal margin *uniformis*. is lighter. Head and thorax greyish-brown with a purple lustre; shoulder-covers are rosy. Hindwings whitish, towards the margin more or less brownish. Expanse of wings: 22 mm. Mexico.

7. Genus: **Diarhabdosia** Hmps.

Differs from *Haematomis* by the well developed proboscis. On the forewing the two lower radial veins and the upper median vein rise separately; the uppermost subcostal vein is only approached to the costal, not coalescent with it. Hindwings like in *Hypoprepia*. 8 species from tropical America.

D. minima Drc. (33 g) differs entirely from the other species. Head and thorax white, abdomen *minima*. orange. Forewings yellowish-white with interrupted, black, oblique transverse lines before, in and beyond the middle, and small, dark antemarginal spots. Hindwings orange. — **rosea** form. nov. (= ab. 1 Hmps.) (33 c) *rosea*. is suffused with rosy on the abdomen and hindwings. Expanse of wings: 20 mm. Mexico to the Amazon.

D. strigipennis Schs. (33 g) is much smaller, otherwise somewhat similar, distinguished by yellow *strigipennis*. hindwings and a yellow abdomen with a red apex; besides the markings of the forewing are different; in the proximal half they are confined almost only to the costal margin. Hindwing with a small blackish-brown apical spot. Expanse of wings: 16 mm. French Guiana.

D. cora Dyar (33 g) has its wings coloured and marked very much like in the following; the apical *cora*. spot of the hindwing is but very small; the species is on the whole much smaller (only 16 mm). French Guiana.

D. laudamia Drc. (= *pusa* Dogn., *peruviana* Schs.) (33 g) is a widely distributed, very common species. *laudamia*. Body yellow with rosy spots on the shoulder-covers and thorax. On the yellowish-brown forewings there are narrow, light-yellow, longitudinal stripes at the costal margin and on the cell-fold; the proximal margin, growing much broader towards the distal margin, is light-yellow, too. Hindwing yellow with a large dark apical spot, in the ♀ brownish-grey like the abdomen. Expanse of wings: 24 to 28 mm. From Mexico through the whole of Central America as far as Ecuador, Peru and Brazil.

D. pueblae spec. nov. (33 h) is very similar, with longer, more slender wings, and a more pointed *pueblae*. apex; the costal-marginal and discal stripes are finer, more distinct, not faded, the inner-marginal stripe somewhat narrower, more uniform. Hindwing at the proximal angle in the ♂ less extended, lighter yellow, the whole costal area grey as far as down to the lower median vein; anal tuft rosy. ♀ much darker, hindwings quite unicolorously blackish-grey. Expanse of wings: 28 to 30 mm. Described according to several couples from Tehuacan (Mexico [Puebla]).

D. coroides Schs. (33 h) likewise greatly resembles the preceding, but it is much smaller, the hindwings *coroides*. in the ♂ dusted brownish-grey except the proximal margin, in the ♀ all brown with white fringes. Expanse of wings: 18 to 20 mm. Costa Rica, Panama.

- melinda*. **D. melinda** Schs. (33 h) is very much lighter than the preceding, light yellowish-white; the discal longitudinal stripe much broader, also the hindwings are much lighter, almost white, with a narrow, brown marginal band. Expanse of wings: 20 mm. Costa Rica.
- mandana*. **D. mandana** Dyar (33 h) is larger, the light yellow proximal margin and distal margin is at the base and before the proximal angle interrupted by dark. Expanse of wings: 24 mm. Brazil: Castro (Paraná).

8. Genus: **Rhabdatomis** Dyar.

Differs from the preceding genus merely by the presence of the middle radial of the hindwing.

- zaba*. **R. zaba** Dyar (34 m) greatly resembles *Haematomis radians* (33 c). Body yellow, on the thorax with a rosy tinge. Forewings grey with yellowish longitudinal stripes at the costal margin, on the median and at the proximal margin. Hindwings whitish, at the proximal margin yellow, at the costal and distal margins darkened brownish-grey. Expanse of wings: 24 mm. Mexico (Orizaba).

9. Genus: **Hypoprepia** Hbn.

Proboscis developed, the porrect palpi project beyond the forehead; the short, thick antennae are very finely serrate, provided with ciliary pencils. Forewings with a curved costal margin; the upper median vein and the lower radials all rise separately, the upper one below the upper cell-angle. On the hindwing the middle radial is absent, the upper one is petioled with the subcostal vein, the lower one with the upper median vein. In their colouring and habitus they somewhat resemble the Arctiid genus *Cissura*.

- miniata*. **H. miniata** Ky. (= vittata Harris) (33 i) is scarlet, on the forewings with brownish-grey longitudinal stripes, on the hindwings with a similar margin and a dorsal spot on the abdomen. — In the form: **subornata** Neum. & Dyar the hindwings are carmine at the margin. Expanse of wings: 32 to 40 mm. Canada and United States. The larva is orange with a dark, on the posterior rings double dorsal stripe, black haired. Head black.
- fucosa*. **H. fucosa** Hbn. (= tricolor Fitch.) (33 i) is smaller, pale yellow-reddish, towards the margin rosy or also entirely rosy except the orange costal margin, and with much broader grey stripes; hindwings rosy, with a broad grey marginal band which in the form: **plumbea** H. Edw. is much narrower and provided with a fine yellow marginal line. Expanse of wings: 30 to 34 mm. From Canada to Texas.
- cadaverosa*. **H. cadaverosa** Streck. is a larger species with a yellow ground-colour, otherwise with the same longitudinal stripes; hindwings quite yellow, with a blackish-brown apical spot. — **dollii** Dyar is a smaller form of only 30 mm from Texas. The type has an expanse of up to 40 mm and flies in the United States (Colorado).
- inculta*. **H. inculta** Edw. (33 i) is dark blackish-brown; shoulders grey; the forewing exhibits only one narrow, yellowish-white longitudinal stripe below the median, dying away towards the margin. Hindwings whitish, towards the margin brownish. Expanse of wings: 34 to 36 mm. Colorado.

10. Genus: **Eurylomia** Fldr.

A few large, yellow species, the ♂ being distinguished by the proximal margin of the forewing and the costal part of the hindwing being very much widened in the shape of a lobe. Veins of the forewing scarcely different from those in *Hypoprepia*; but the upper radial vein comes from the upper cell-angle. The hindwings are likewise similar; the transverse vein, however, is strongly angled, and the upper median vein comes from below the lower cell-angle; the upper radial vein comes either together with the subcostal from the upper cell-angle, or it is petioled with it.

- ochreata*. **E. ochreata** Drc. (33 k) is orange-yellow; antennae, legs, and lateral stripes on the abdomen are black like the borders of the wings. Expanse of wings: 56 mm. Honduras.
- similliforma*. **E. similliforma** Rothsch. (33 i) is extremely similar, smaller and more slender, with broader wings, deviating by the blackish-brown abdominal end; the borders of the wings are more blackish-brown, dusted grey. Expanse of wings: 48 mm. Cuba?
- cordula*. **E. cordula** Bsd. (= curvinervis Fldr.) (33 i) is likewise similar, though easily recognizable by the two black longitudinal stripes of the forewing on the discal and submedian folds; the black colour exhibits a green lustre. Expanse of wings: 50 mm. From Mexico and Honduras.

11. Genus: **Neoplynes** Hmps.

Different from the preceding genus by the antennae being long-combed in the ♂; the 1st palpal joint long haired; 2nd and 3rd joints shorter. On the forewing the two lower radial veins rise from the same place. On the hindwing the middle radial vein is present and rises above the cell-angle, from which the lower radial vein comes together with the upper median vein. 2 species known of this genus.

N. cytheraea Drc. (33 k) has grey-brown forewings with light yellow costal-marginal and inner-marginal stripes, hindwings yellow, anteriorly brownish. Body orange-yellow; spots on the shoulder-covers and the underside are black. Expanse of wings: 34 mm. Mexico. *cytheraea*.

N. eudora Dyar (33 k) is a quite unicolorously yellowish white animal; only the neck is orange, and the combs of the antennae are black. Expanse of wings: 26 mm. Texas. *eudora*.

12. Genus: **Leptopepla** Hmps.

Distinguished from the preceding by longer, erect palpi and very thinly scaled wings. On the forewing the upper radial vein rises below the cell-angle, the 4 lower subcostal veins rise from one pedicle. On the hindwing the upper median vein rises from below the cell-angle.

L. procridiformis Hmps. (33 h) is a one-coloured blackish-brown, small animal, thinly covered with diaphanous scales. Expanse of wings: 22 mm. Bolivia, Peru. *procridiformis*.

13. Genus: **Euclemensia** Hmps.

Proboscis developed. Palpi long and thin, erect, projecting beyond the vertex; ♂ antennae with ciliary pencils. On the forewing the upper median vein rises before the cell-end, the two lower radial veins from the lower angle, the upper one from the upper angle; the 3 lower subcostal veins petioled, the two upper ones likewise. On the hindwing the upper median and lower radial vein are coalescent, the middle one from the lower cell-angle, the upper one being petioled with the subcostal. The genus was based upon 1 species captured by A. H. FASSL at the Quindiu Pass in Colombia.

E. umbrata Dogn. (34 m). Body white, on the thorax mixed with red-brown. Forewings white with brown antemedian, median and postmedian transverse lines, between the middle one and distal one dusted red-brown and strewn with black, with a black cell-spot; before the margin red-brown dusting. Abdomen and hindwings white. Expanse of wings: 26 mm. Colombia. *umbrata*.

14. Genus: **Adoxosia** Hmps.

Different from the preceding genus by somewhat shorter, straightly porrect palpi; on the forewing the upper radial vein rises from below the upper cell-angle; the two upper subcostal veins rise separately, the uppermost anastomoses with the costal; on the hindwing the upper median vein and the lower radial veins all rise separately. Only 1 species:

A. excisa Hmps. (33 k) is yellowish-white, dusted brown, on the forewing with indistinct, darker lines. Hindwings yellowish-white, at the margin brownish. Expanse of wings: 20 mm. Brazil (Rio de Janeiro). *excisa*.

15. Genus: **Eutelesia** Hmps.

Differs from *Adoxosia* by combed antennae; on the forewing the middle subcostal vein is absent; on the hindwing the middle radial comes from the middle of the transverse vein, otherwise not different. Up to this day 2 dark smoky brown species are known, very much like each other, from Colombia and Costa Rica.

E. vulgaris Drc. (33 k) is light ochreous brown, on the forewings strewn with dark brown, with an indistinct, brown, oblique antemedian line, black dots at the cell-end and beyond the middle, a double ante-marginal row of dark dots, and black marginal streaks. Forewings light yellowish. Expanse of wings: 20 mm. Costa Rica. *vulgaris*.

E. phaeochroa Hmps. (33 k) is red-brown, on the forewings darker, in the basal area and at the costal margin more ochreous-yellowish. Expanse of wings: 18 mm. Colombia. *phaeochroa*.

16. Genus: **Clemensia** Pack.

Proboscis developed, palpi erect, reaching the vertex; posterior tibiae with long spurs. Abdominal end long haired. On the forewing the middle radial vein rises from the lower cell-angle or above it, or on a short pedicle with the lower one; the upper one rises from below the upper cell-angle. Hindwings like in the preceding genus, but the middle radial comes more from near the lower cell-angle. — In 1900 only one dozen species were known (according to HAMPSON). Today the number has increased to almost three times as many. The insignificant species slightly recalling *Nola* by their habitus are confined to the neotropical region except two, one of which scarcely proceeds beyond the nearctic frontier, while the other goes as far as New England. The latter species being sometimes of a pure, sometimes dull whitish-grey, clouded or speckled, has, according to its colouring, received 5 different names.

- ophrydina*. **C. ophrydina** Drc. (= *pico*a Dogn.) (33 k) is a widely distributed common species having the antennae provided with ciliary pencils, similar to the following. Forewings white, spotted black, hindwings towards the margins brownish. Beneath the ♂ has a hairy costal fold of the forewing and a hair-tuft on the inner-marginal vein, the hindwing exhibits behind the cell a fold, being on both sides hairy, between the upper radial veins. Expanse of wings: 24 mm. Mexico; Guatemala; Ecuador.
- marmorata*. **C. marmorata** Schs. (33 i) has doubly combed antennae. Body and forewings white, the latter with red-brown and bluish-grey spots and a black, distally greyish-brown, post-median undulate line. Hindwing with a brownish marginal band. Expanse of wings: 20 mm. Brazil.
- fuscipes*. **C. fuscipes** Grt. is one-coloured brownish-black, on the forewings semi-diaphanous, strewn with dark scales. Expanse of wings: 22 mm. United States, Arizona.
- acropera*. **C. acropera** Jones (36 c) has likewise eombed antennae, and is sufficiently recognizable by the apex of the forewing being pointed in the shape of a sickle, with another projection in the middle of the margin. Body greyish-brown, abdomen lighter. Forewings white, dusted brownish, at the costal margin, apex and marginal area darker, with 3 irregularly undulated, brown transverse lines and a small black discal spot. Fringes light, at the apex, the middle of the margin and the anal angle blackish. Hindwings white. Expanse of wings: 20 mm. Brazil: Castro (Paraná).
- cinnamomata*. **C. cinnamomata** Schs. (33 l) has the same scent-markings of the forewings, on the hindwing the whole cell above is covered with yellow scent-scales. Body dark brown, mixed with white on the head and thorax. Forewings white, thickly strewn with blackish-brown. Median area in the inner-marginal half more densely dusted with small black spots, and a postmedian dentate transverse line. Hindwings blackish-brown, in the costal half more yellowish-white. The ♀ with a white anal tuft has more purely white forewings, without any brown dusting, and quite dark hindwings. Expanse of wings: 20 to 22 mm. Costa Rica.
- alembis*. **C. alembis** Dyar (33 k) shows beneath the same secondary sexual marks as the preceding species and is also above very similar, but the costal margin is not so very convex. On the forewing there is a very prominently black bent antemedian band, and in the middle a band composed of spots. Expanse of wings: 21 mm. Mexico.
- leisova*. **C. leisova** Dyar (33 l) has the same under surface and likewise a similar upper surface; the forewing is very much suffused with red-brown in the inner-marginal area; here the cell of the hindwing above also exhibits yellow scent-scales; the hindwings are otherwise much lighter, almost white, only at the margin brownish. Expanse of wings: 22 mm. Mexico.
- leopardina*. **C. leopardina** Schs. (33 l) is greyish-white on the forewings, with numerous rows of black spots. The species is easily recognizable by the submedian fold being coloured orange in the middle. The whitish hindwings are brownish towards the margin. Expanse of wings: 24 mm. Costa Rica.
- reticulata*. **C. reticulata** Roths. (33 l) is easily recognized by the neat, black, postmedian venation being edged by fine black transverse lines. Abdomen dark with an ochreous-yellow anal tuft. Expanse of wings: 18 mm. Peru.
- albata*. **C. albata** Pack. (= *albida* Wkr., *cana* Wkr., *irrorata* Edw., *patella* Drc., *philodina* Drc.) (33 l) is an extremely common and widely distributed animal and very variable. White, anterior body suffused with brownish, abdomen dark-banded. Forewing with numerous small black spots being arranged to transverse lines behind the middle, before the middle with two fine black transverse lines. — In the form: **umbrata** Pack. there appears a median shade dusted dark brown. The whitish hindwings exhibit a small, indistinct discal spot, traces of a dark line behind it and small faint spots before the margin. Expanse of wings: 22 to 28 mm. Through the whole of North America and Mexico as far as Costa Rica. — The larva is whitish green, with fine hair, and a dark brown head.
- urucata*. **C. urucata** Dogn. (33 l). Forewings very prominently dusted light red-brown in the lower cell-half, below it and behind it; otherwise strewn with black scales, and with a broad, black, curved antemedian band before the black anterior transverse line; in and behind the middle there are besides brownish transverse lines, and before the margin a black macular band. Hindwings yellowish-white. Expanse of wings: 24 mm. Costa Rica.
- maculata*. **C. maculata** Roths. (33 l) is a tiny animal, easily recognizable by the broad, blackish-brown antemedian band of a silvery blue lustre, and two large, similar spots in and behind the cell. Hindwings blackish-brown. It was described as *Disoidemata*. Expanse of wings: 14 mm. Peru.
- lactea*. **C. lactea** Stretch. (33 l). This species, described as *bisthene*, was formerly inserted in *Illice*. It is quite white, palpi black, antennae brown. The forewings exhibit single, small, brownish-grey spots before, in and behind the middle. The under surface is dusted brownish-grey. Expanse of wings: 18 mm. California.
- brunneo-media*. **C. brunneomedia** Schs. (34 m) [is to be recognized by the roughly haired costal margin projecting in the middle in the ♂, below the costal margin on the upper surface a roughly haired spot; on the under surface the usual hairy subcostal fold and a long hair-pencil on the proximal margin are present. The grey forewings,

dusted reddish-brown and strewn with a dark tinge, exhibit a broad, red-brown median band between 2 irregular transverse lines. Hindwings whitish, dusted brown. Expanse of wings: 20 mm. Costa Rica.

C. roseata *Hmps.* (33 m) has beside the subcostal fold a hairy spot in the cell-end and a curved hair-stripe in the submedian space on the forewing beneath. Forewings yellowish rosy with brownish spots and transverse lines. Hindwings light yellow. Expanse of wings: 26 mm. Brazil (Petropolis). *roseata*.

C. abnormis *Schs.* (33 m). Body yellowish white, also the forewings which, for the greatest part, except the costal margin and the apical third, are dusted chrome-yellow; the light apical third is bordered by an oblique dark line; an anterior transverse line is indistinct. Hindwings yellowish-white with a large dark spot in the middle of the margin. Expanse of wings: 18 mm. French Guiana. *abnormis*.

C. subleis *Schs.* (34 m). The ♂ exhibits only a large, brown scent-scale spot at and behind the cell-end of the forewing beneath, the hindwings above a long black scent-scale stripe below the costal margin. Forewings greyish-white, dusted brownish, particularly in the middle area; before and in the middle single black dots, behind it a dentate transverse line. Hindwings brownish-grey. Expanse of wings: 16 mm. French Guiana. *subleis*.

C. inleis *Schs.* (34 m) is a similar small species recognizable by the absence of the lowest subcostal vein on the forewing. The ground-colour is a light red-brown, scantily strewn with a darker tinge, with single small black dots; before the apex with a small dark spot. Hindwings yellowish-white with a small discal spot. Expanse of wings: 16 mm. Brazil. *inleis*.

C. erminea *Schs.* (32 m). Purely white, with black costal-marginal spots and a dark, blackish marginal area. Expanse of wings: 14 mm. Brazil: Castro (Paraná). *erminea*.

C. cernitis *Drc.* (33 m) is a larger, grey species. Forewings with a blackened base of the costal-margin; before and in the middle finely dentate, dark transverse lines; between the median line and a postmedian row of dots there is, at the costal margin, a triangular dark spot; before the margin a faded, twice angled line; at the margin itself there are black streaks and small spots. Hindwings blackish-brown. Expanse of wings: 20 mm. Mexico (Guerrero). *cernitis*.

C. distincta *Schs.* (33 m) entirely resembles *acropera* by the shape of the wings. The colour is blackish-brown with a leaden lustre; faded, darker lines are before and in the middle; a postmedian row of dots is distally tinged whitish; marginal area still darker with a line of whitish dots before the fringes. Expanse of wings: 20 mm. Trinidad. *distincta*.

C. centralis *Hmps.* (33 m). Ground-colour brown, vertex, collar and anal tuft whitish. Forewings strewn with black, with a black discal dot, and finely dentate, antemedian and postmedian transverse lines being outside bordered with whitish; behind them dark dots on the veins, and before the margin a line of white dots. Hindwings blackish-brown. Expanse of wings: 16 mm. Guatemala; Panama. *centralis*.

C. quinqueferana *Wkr.* (33 m) is a very small, red-brown species with indistinct oblique transverse lines and a dark discal spot. Fringes whitish, at the apex and middle darkened. Hindwings whitish, at the margin brownish. Expanse of wings: 14 mm. Widely distributed from Mexico, Panama through Brazil as far as Peru. *quinqueferana*.

C. russata *Hmps.* (= *vulgaris* *Drc.*) (33 m) greatly resembles the preceding, but it is much larger and differs by much lighter hindwings; on the forewing the transverse lines are more distinct and more complete. Expanse of wings: 24 mm. Costa Rica. — In the form: **nigriplaga** *nov.* (33 m) there is in the middle of the proximal margin a large, black spot; **infuscata** *form. nov.* (33 m) is entirely darkened by black. *russata*. *nigriplaga*. *infuscata*.

C. nubila *Jones* (33 p). Head, thorax and forewings yellowish white, the latter dusted red-brown and strewn with black, particularly in the basal and marginal area; close behind the base a curved black line, behind it a black nebulous band, followed by a row of dots; the middle is crossed by a strongly undulate transverse line; at the cell-end a black streak with a black dot below it; beyond the middle a row of black dots, and before the margin a black macular band, on the margin black streaks. Abdomen and hindwings white, the latter at the proximal and distal margins dusted red-brown. Expanse of wings: 18 mm. Brazil. *nubila*.

C. parapatella *Dogn.* (33 m) greatly resembles *nubila*, but it is larger, more grey, dusted brown, particularly the abdomen much darker; on the forewing there is no shade behind the black subbasal line. Expanse of wings: 22 mm. Ecuador. *parapatella*.

C. mesomma *Dogn.* (33 n) is one of the largest species, the wings very large and broad compared with the slender, slim abdomen. Greyish-white, dusted reddish-brown. Very characteristic is the small eye-spot formed by the cell-end spot being encircled by the median line. Expanse of wings: 28 mm. Colombia. *mesomma*.

C. mucida *Schs.* (33 p) is whitish, dusted and strewn with dark-brown, in the distal half of the median area suffused with red-brown in the shape of a transverse band, with the usual transverse lines and dots. Hindwings blackish-brown. Expanse of wings: 16 mm. Costa Rica. *mucida*.

- leucogramma*. **C. leucogramma** Dogn. (33 n) is a very small, dark red-brown species; the anterior and posterior transverse lines are on the averted sides tinged white; before the margin there is a series of white streaks. Hindwings whitish, dusted red-brown, particularly towards the margin. Abdomen darker brown. Expanse of wings: 16 mm. Panama.
- lacteata*. **C. lacteata** Hmps. (= *lactea* Rothsch. nec Stretch.) (33 n) is one of the smallest species. Body white, above mixed with brownish, forewings white, scantily strewn with a blackish brown; at the costal margin there are 4 black spots; from the second spot there proceeds a transverse line, from the third a row of dots; before the margin some more small, black dots and streaks. Hindwings white, towards the margin brownish. Expanse of wings: 14 mm. Peru.
- irrorata*. **C. irrorata** spec. nov. (33 n). Very much like the preceding, much more intensely strewn with brown; all the transverse lines broken up into dots, the posterior line double, towards the costal margin connected to strong, double dentate lines; before the margin strong, black, wedge-shaped streaks. Forehead all white, in *lacteata* brown. Expanse of wings: 14 mm. Peru (Cuzco).
- panthera*. **C. panthera** Schs. (33 m). Forewings white with numerous black dots. Abdomen ochreous-yellow. Hindwings white, towards the margin brownish. It differs from the very similar *ophrydina* by the abdomen and by the absence of the hairy spots beneath. Expanse of wings: 22 mm. Brazil (São Paulo).
- flava*. **C. flava** Jones (33 n) is a very easily recognizable species by the yellow colour; on the unmarked forewings the costal margin is blackish-brown as far as the middle. Abdomen above and hindwings lighter yellow. Expanse of wings: 22 mm. Brazil (Paraná).

17. Genus: **Anaulosia** Schs.

Characteristic by the apex of the forewing being sharply and pointedly extended, below which the border is deeply notched. Palpi longer and more slender than in *Clemensia*; venation of the forewings like there, except the upper radial rising from the upper cell-angle; veins of the hindwings like in *Barsinella*; the middle radial comes from the middle of the transverse vein.

- impolita*. **A. impolita** Schs. (34 m) is a one-coloured, small, brown insect, dusted leaden-grey on the anterior body and forewings; abdomen more greyish-brown. Expanse of wings: 18 mm. Costa Rica. The type was brought from Guapiles by SCHAUS and is in the National Museum of Washington.

18. Genus: **Paratalara** Dyar.

Proboscis developed, palpi short, porrect. On the forewing the two lower radial veins are long petioled, the upper one with the 3 lower subcostal veins on a joint pedicle; the middle subcostal vein is absent. On the hindwing the middle radial vein rises yet above the middle of the transverse vein, the upper end of which is strongly produced. Only one very small species forms this genus; the type is in Washington in the National Museum and originates from the Maroni River in Guiana.

- inversa*. **P. inversa** Schs. (34 m). Body white, on the abdomen mixed with brownish. Forewing in the basal half of the costal margin and in the apical third white, otherwise dusted blackish-brown, with a red-brown postmedian band, distally bordered by white. Apex likewise dusted red-brown. Hindwings lighter brownish, at the costal margin whitish. Expanse of wings: 16 mm. French Guiana.

19. Genus: **Epitalara** Dyar.

Proboscis developed; palpi longer than in the preceding genus. On the forewing the upper median vein is petioled with the lower radial, the middle one from the lower cell-angle, the upper one from the upper cell-angle. Hindwings like in the preceding, but the middle radial vein is altogether absent. Only 2 species:

- reversa*. **E. reversa** Schs. (34 m). Body and forewings white, strewn with brownish; apical half quite red-brown with a white apical spot in it; before and behind the middle indistinct dark transverse lines; before the margin single small white spots, fringes white and speckled blackish-brown. Hindwings brownish-grey. Expanse of wings: 14 mm. French Guiana.
- commixta*. **E. commixta** Schs. (34 m) is distinguished by scent-scale spots in the upper cell-angle of both wings beneath; on the forewing the median is at the base very much bent upwards. Anterior body white with a brown mesothorax, abdomen greyish-brown. On the white forewing with a broad, red-brown median band there are in the basal and marginal area faded, small, red-brown spots. Hindwings white. Expanse of wings: 18 mm. Costa Rica.

20. Genus: **Palpidia** Dyar.

The long, slender palpi are obliquely turned upwards; posterior tibiae with long spurs. Antennae ciliated, forewings narrow and long, veins like in the preceding genus, the 3 or 4 lower subcostal veins on one pedicle. On the hindwing the upper median and lower radial vein are petioled; the middle radial comes from above the lower cell-angle, the upper one with the subcostal from the same spot or petioled.

- pallidior*. **P. pallidior** Dyar (33 n) resembles *Agylla* and is ochreous yellowish-white, in the cell-spaces dusted brownish. Hindwings and abdomen white. Expanse of wings: 30 mm. Florida.

P. melanotricha *Hmps.* has much broader wings and much shorter palpi. Body white, mixed with ochreous-yellow, forewings white, watered with a golden brown, with long black haired scales before, in and behind the middle; before and behind the middle one dark brown transverse line each, and before the margin a white undulate line. Hindwings white, on the veins and margin brownish. Expanse of wings: 16 mm. Jamaica.

21. Genus: **Lerina** *Wkr.*

The genus contains only one animal entirely Arctiid-like, with a stunted proboscis, long haired palpi, and doubly combed antennae. Body shaggily haired. On the forewings the venation is almost like in the preceding genus, but the upper median vein rises unpetaled before the lower cell-angle; on the hindwings likewise; the two lower radial veins from the lower cell-angle, the upper one with the subcostal from the upper angle or on a short pedicle. The larva also entirely resembles an Arctiid by its habitus. Only 1 species:

L. incarnata *Wkr.* (= *robinsonii* *Bsd.*) (34 a) is jet-black, with a bronze green reflection on the wings; head, collar and shoulder-covers, and the abdominal end deep carmine, the latter with small black dorsal spots. Expanse of wings: 46 mm. — The larva is yellowish-white with long hair of a reddish fawn tint on black warts, head light red-brownish. It lives on *Asclepias pumila*. Mexico.

22. Genus: **Neotalara** *Hmps.*

Very closely allied to the following genus and distinguished almost only by the uppermost radial vein on the forewing being petioled with the 3 lower subcostals. Only 1 species:

N. metamelaena *Hmps.* (34 h). Body greyish-white mixed with brownish. Forewings greyish-white, strewn with brown, except the light marginal area, at the base of the costal margin and at the proximal margin more densely; brown postmedian transverse shades. Hindwings black, at the base, proximal and distal margin greyish-brown. Expanse of wings: 16 mm. Ecuador.

23. Genus: **Talara** *Wkr.*

Proboscis developed; the porrect palpi project yet beyond the forehead; antennae ciliated, abdomen roughly haired. On the long, narrow forewings the upper radial vein rises below the lower cell-angle, the 3 lower subcostal veins are petioled, the 4th is separated, the uppermost anastomoses with the costal vein. On the hindwings the upper median vein rises with the lower radial from the same spot or petioled, the middle radial is absent, the upper one coalesces with the subcostal vein. Numerous, mostly variegated, yellow and red, small species.

T. ditis *Btlr.* (34 a) is orange, anterior body and veins of the forewing coloured red; small stripes at the base of the costal margin; 2 dentate transverse lines and minute spots before and behind them are black. Hindwings dusted carmine. Expanse of wings: 14 to 16 mm. Brazil.

T. esperanza *Schs.* (32 n) is very similar, on the wings much paler, the whole body light scarlet, the black transverse lines finer, the whole space in front of the anterior transverse line thickly strewn with black. Expanse of wings: 14 to 16 mm. Costa Rica.

T. subcoccinea *Schs.* (34 a) is larger than the preceding; pale reddish-brown, strewn darker with 2 indistinct dark transverse lines in the inner-marginal half. Hindwings and abdomen light carmine. Expanse of wings: 20 mm. French Guiana.

T. ornata *Schs.* (34 a). Thorax blackish, spotted white; head and collar are like the forewings whitish, dusted brown; abdomen carmine, with a black apex, beneath whitish. At the proximal margin of the forewing there is before the middle a white, oblong spot and a red-brown spot behind the middle of the costal margin; at the cell-end a black dot and in the lower marginal half a faded, blackish band. Hindwings red with a black margin. Expanse of wings: 18 mm. French Guiana.

T. lepida *Schs.* (32 n) is brown on the anterior body and forewings, strewn with greyish-white scales, in the marginal area lighter. Abdomen and hindwings carmine, the latter with a red-brown marginal band. Expanse of wings: 14 mm. Costa Rica.

T. barema *Schs.* (34 a) is whitish, densely dusted brown, and on the forewings strewn with black; in and below the cell-end a small black spot, behind it another, still more indistinct spot. Hindwings and abdomen light yellow. Expanse of wings: 18 mm. Brazil (São Paulo).

T. leucocera *Drc.* (34 a) is yellowish-white on the anterior body and forewings, dusted red-brownish with a small dark median spot on the latter. Abdomen and hindwings light red. Expanse of wings: 18 mm. Brazil (Espírito Santo).

- alborosea*. **T. alborosea** *Rothsch.* (32 n). Anterior body and forewings of a silvery white, the latter scantily strewn with coarse black scales, before the middle of the proximal margin with a small, black spot, cellular spot and longitudinal stripe from the middle of the cell to the proximal angle. Abdomen and hindwings carmine. Expanse of wings: 16 mm. Venezuela.
- albipars*. **T. albipars** *Hmps.* (32 n) resembles an *Illice*: anterior body and forewings brown, mixed with whitish and strewn with black, with 2 large white spots at the proximal margin before and behind the middle. Abdomen and hindwings carmine, the latter with a dark marginal band. Expanse of wings: 14 mm. Ecuador.
- niveata*. **T. niveata** *Btlr.* (34 a) is white on the anterior body and forewings, scantily strewn with blackish, with small faded spots below the base of the cell and behind the middle of the proximal margin. Abdomen carmine, hindwings blackish-brown with a red spot at the base of the proximal margin. Expanse of wings: 18 mm. Brazil (Espiritu Santo).
- nigroplagiata*. **T. nigroplagiata** *Rothsch.* (34 a) greatly approximates *alborosea* and differs by the dark border of the hindwings; the dark spot at the base of the proximal margin is absent. — **suffusa** *form. nov.* (= ab. 1 *Hmps.*) is almost entirely strewn brown, so that there remains only a light spot of the ground-colour before the dark inner-angular spot. Marginal band of the hindwing broader. Expanse of wings: 16 mm. Venezuela; Bolivia.
- leucophaea*. **T. leucophaea** *Dogn.* (33 o) is dirty white, scantily strewn with blackish-brown, in the apical half of the forewing more densely so. Abdomen carmine, hindwings blackish-brown, at the proximal margin light red. Expanse of wings: 16 mm. French Guiana.
- cinerea*. **T. cinerea** *Hmps.* (33 p) is quite unicolorously blackish-brown, on the anterior body dusted grey, on the forewings strewn with black. Expanse of wings: 18 mm. Colombia.
- chionophaea*. **T. chionophaea** *Hmps.* (33 o) differs by its rosy abdomen. Head and thorax are more whitish, like the forewing in the apical half of the margin; in front of it somewhat more densely dusted brown. Expanse of wings: 20 mm. Brazil.
- violaceogrisea*. **T. violaceogrisea** *Rothsch.* (32 m) is on the anterior body and forewings more red-brown, with a purple lustre, abdomen and hindwings red-brown, both towards the bases lighter. Expanse of wings: 18 mm. British Honduras, Surinam, Ecuador.
- brunnescens*. **T. brunnescens** *Rothsch.* (33 o) is extremely similar, of a purer red-brown, only on the head and forewings near the cell-end strewn with whitish. Expanse of wings: 18 mm. Peru.
- megaspila*. **T. megaspilea** *Wkr.* (34 b) is orange-red on the anterior body, first abdominal ring and forewings; on the latter there is an antemedian, black transverse band striped metallic blue, growing narrower towards the costal margin, an oblong, small spot at the costal margin before the apex and a very large marginal spot below the apex. Hindwings blackish-brown, at the base red. Abdomen brown. Expanse of wings: 20 mm. Amazon.
- ignibasis*. **T. ignibasis** *Rothsch.* (33 o) is very similar, more scarlet, the marginal spot and antemedian spot flown together. Expanse of wings: 18 mm. Peru.
- togata*. **T. togata** *spec. nov.* (33 o) has scarlet forewings, being obliquely cut off by black in the marginal halves, with metallic blue longitudinal stripes. Anterior body and the first abdominal rings red, the rest black like the hindwings the bases of which are red. Expanse of wings: 20 mm. Described according to 2 ♂♂ from the Rio Negro (Colombia) from the Coll. FASSL.
- cara*. **T. cara** *Schaus* (33 o) is orange-red on the anterior body and forewings, the latter blackish-brown at the distal margin. Abdomen and hindwings blackish-brown, both towards the bases orange-red. Expanse of wings: 18 mm. Costa Rica.
- semiflava*. **T. semiflava** *spec. nov.* (33 o) differs from *cara* by its yellow, not orange-red colour, and twice as broad black margin. Expanse of wings: 18 mm. 1 ♀ from Muzo (Colombia), Coll. FASSL.
- coccinea*. **T. coccinea** *Btlr.* Head and thorax carmine, abdomen blackish-brown; forewings scarlet, towards the margin warming into orange with a black, blue-scaled spot behind the middle of the costal margin. Hindwing blackish-brown, at the base red. Expanse of wings: 20 mm. Amazon.
- miniata*. **T. miniata** *Rothsch.* (33 o) differs from *coccinea* by its quite blackish-brown hindwings and an ante-marginal band dusted brownish on the forewing. Anterior body and forewings are uniformly scarlet. Expanse of wings: 18 mm. Venezuela; Brazil.
- rubida*. **T. rubida** *Schs.* (33 o) is likewise very much like the preceding; the oblong black costal-marginal spot is entirely absent; behind the cell there is a dark shade; hindwing at the base red. Expanse of wings: 20 mm. Costa Rica.
- rufa*. **T. rufa** *Schs.* (33 n). Anterior body and forewings red-brown, strewn with a darker tinge; from the middle of the cell to the proximal margin an oblique black line; before the fringes speckled black and white there are some small darker spots. Abdomen and hindwings orange-yellow, suffused with rosy. Expanse of wings: 20 mm. Brazil; Castro (Paraná).

T. decepta Schs. (= *aenia* Rothsch.) (33 n). Anterior body and forewings blackish-brown with a *decepta*. leaden-blue reflection; vertex, and a median band interrupted in the middle on the forewing, are yellowish-white, as well as a tiny spot above the proximal angle. Costal margin in the basal half red-brown. Hindwings brownish-black, towards the base lighter; abdomen bluish-black. Expanse of wings: 20 mm. French Guiana; Surinam.

T. rufibasis Fldr. (34 c). Anterior body and forewings brownish-black, strewn with grey; black *rufibasis*. remain the costal and proximal margins, the cellular and submedian folds, and a faded postmedian transverse band. Abdomen earmine with an ochreous-yellow anus and black venter. Hindwings blackish-brown with a red inner-marginal area. Expanse of wings: 18 mm. Panama; Colombia.

T. bicolor Rothsch. (34 c). Head and thorax dark red-brown, abdomen carmine, beneath red-brown. *bicolor*. Forewings and hindwings likewise red-brown, the latter with a red inner-marginal area. Expanse of wings: 22 mm. Colombia.

T. grisea Schs. (34 c) is similar, though smaller, more blackish-brown, hindwings much lighter *grisea*. without a red inner-marginal spot. Expanse of wings: 18 mm. Brazil (São Paulo).

T. diversa Schs. (34 c). Head and thorax brown mixed with whitish; abdomen earmine with a dark *diversa*. anal tuft. Forewings whitish, strewn with brown; near the base a red-brown costal-marginal spot, another one in the middle, being united with a blackish-brown spot near the proximal angle; a postmedian, interrupted, whitish line, behind it at the apex red-brown. Hindwing red with a dark marginal band. Expanse of wings: 16 mm. French Guiana.

T. unimoda Schs. (34 c). Anterior body and forewings dull brown, the latter with traces of undulate, *unimoda*. light antemedian and postmedian lines, and a dark cell-dot. Abdomen and hindwing earmine, the latter with a blackish-brown marginal band. Expanse of wings: 16 mm. French Guiana.

T. rugipennis Schs. (34 c) is unicolorously blackish-brown except the red abdomen, on the more *rugipennis*. greyish-brown forewings roughly strewn with black and whitish scales. Expanse of wings: 16 mm. French Guiana.

T. bombycia Schs. (33 p). Head, thorax and abdomen blackish-brown, the latter on the first ring *bombycia*. whitish. Forewings likewise blackish-brown, with whitish, dentate, ante- and postmedian transverse lines enclosing a whitish-dusted discal area with a black cell-spot. Hindwings blackish-brown. Expanse of wings: 18 mm. Brazil (São Paulo).

T. phaeella Hmps. (32 m) is similar, much smaller; the median area of the forewings is not so decidedly *phaeella*. lighter, the posterior transverse line which in *bombycia* forms distally a sharp tooth on the upper radial vein, is here uniformly bent outwards in the middle. Expanse of wings: 14 mm. Panama.

24. Genus: **Barsinella** Btlr.

In the venation of the forewings it scarcely differs from *Talara*; the wings are broader and shorter; on the hindwings, however, the upper median and lowest radial vein are coalescent; the middle radial is present and rises above the lower cell-angle, the upper one rises on a long pedicle with the subcostal vein. The ♂ exhibits beneath on the forewing a hairy costal fold ending in a thickening in the middle of the costal margin; below it, round the cell-end, long hairs turned backwards; the costa of the hindwing is long-haired. Only 1 species known:

B. mirabilis Btlr. (= *expandens* Rothsch.). Body and forewings orange-yellow; the latter with *mirabilis*. 4 black, strongly dentate, transverse lines being broken up into dots before the margin; 1 long discal streak and a line before the fringes are earmine like the hindwings. Expanse of wings: 16 mm. Brazil.

25. Genus: **Aethosia** Hmps.

Distinguished by the concave indentations of the forewings above the proximal angle, of the hindwings in the middle of the margin. The venation very much like in *Talara*. Costal margin of the forewing strongly curved, the uppermost subcostal vein only nearer to the costal-marginal vein; on the hindwing the subcostal vein rises already before the upper cell-angle. The ♂ exhibits beneath a long, elliptic scent-scale spot above and below the median on the forewing, and a similar one on the upper surface above the subcostal vein. Venation otherwise like in *Talara*. Hitherto only 1 West Indian species known.

A. ectrocta Hmps. (34 c) is yellowish-white on the body and wings, on the hindwings and abdomen *ectrocta*. with a rosy tinge. Forewings strewn with blackish scales, and with 2 blackish transverse lines. Expanse of wings: 30 mm. Hayti.

26. Genus: **Paramulona** Hmps.

Differs from *Talara* by ascending palpi, in the ♂ combed antennae; on the forewing the two lower radial veins are petioled, on the hindwing the lowest with the upper median vein; the subcostal is removed

to the upper cell-end and rises from the same place with the upper radial vein. One small, West Indian species.
albulata. **P. albulata** H.-Schäff. (34 c). Head and thorax brown and black. Forewings pale brownish-yellow, densely and irregularly dusted purple-brown. Abdomen and hindwings pale brownish-yellow; antennae whitish, spotted darker. Expanse of wings: 24 mm. Cuba.

27. Genus: **Neomulona** Hmps.

Proboscis absent; palpi more slender than in the preceding genera and longer erect; ♂ antennae ciliated. On the forewing the upper median vein and the two lower radial veins rise close together from the lower cell-angle, the upper radial from the upper cell-angle. On the hindwing the middle radial is absent, the lower one coalesces with the upper median vein; the upper radial is petioled with the subcostal vein. 1 very small species from South Brazil.

torniplaga. **N. torniplaga** Jones (32 m). Head, thorax, and forewings light yellow; the latter exhibit 3 reddish-brown, dentate transverse lines partly broken up into dots; the median area between them dusted red-brown, in it a black discal dot. Abdomen and hindwings white. Expanse of wings: 16 mm. Brazil (São Paulo).

28. Genus: **Mulona** Wkr.

Differs from the preceding genus by the proboscis being fully developed. On the forewing the upper radial vein comes from below the upper cell-angle. On the hindwing the upper median vein is on a short pedicle with the lower radial, the middle one being absent; the subcostal vein rises already before the upper cell-angle. There are 4 species known from the West Indies, Colombia, and Panama.

phelina. **M. phelina** Drc. (34 c) is yellowish-white on the anterior body and forewings, on the latter with rows of black dots; fringes orange like the hindwings and abdomen. On the hindwing a blackish spot at the costal margin before the apex. Expanse of wings: 20 mm. Panama.

lapidaria. **M. lapidaria** Wkr. (34 d) is white, dusted brown, and on the forewing with black dots partly flown together to dentate transverse lines. Hindwing towards the margin brown. Expanse of wings: 22 mm. Hayti.

nigripuncta. **M. nigripuncta** Hmps. (32 l) greatly resembles *lapidaria*, forewings more yellowish-white, more profusely strewn with black; in the cell-end a short, orange stripe; a costal-marginal stripe beyond the middle being present in the preceding is absent here. Head and thorax more red brown. Expanse of wings: 18 mm. Porto Rico; Colombia.

grisea. **M. grisea** Hmps. (32 l) differs by much darker, blackish-brown hindwings. Forewings grey, densely dusted blackish-brown, similarly marked as the two preceding. Expanse of wings: 22 mm. Jamaica.

29. Genus: **Cincia** Wkr.

Differs from the preceding by the antennae being in the ♂ serrate or combed; on the hindwing the upper radial vein is petioled or unpetholed with the subcostal. All the rest as in *Mulona*. 4 species from the West Indies and Mexico.

pallida. **C. pallida** Btlr. (= mixta *Mschlr.*). Body blackish-brown, forewings strewn with black, and with black dots; costal margin white with 6 black dots and with yellow-dusted ante- and postmedian spots. Hindwings blackish-brown. The ♀ is of a more white ground-colour, more profusely strewn with black, with larger spots. Expanse of wings: 26 to 28 mm. Jamaica.

nephelistis. **C. nephelistis** Hmps. (34 g) is light rosy on the body and forewings, strewn blackish, partly in the shape of spots; veins black; costal margin of a deeper pink colour. Hindwings in the ♂ white, at the costal margin and apex darkened, in the ♀ quite dark. Expanse of wings: ♂ 24, ♀ 26 mm. Cuba.

mülleri. **C. mülleri** Dyar (34 d) is a larger species with dark brown forewings and body; base and end of abdomen carmine-rosy, so are small spots on shoulders and base of proximal margin on the forewing. Hindwings rosy, towards the margin dusted brown. Expanse of wings: 30 mm. Mexico.

conspersa. **C. conspersa** Wkr. (= sordida *Mschlr.*) (34 d) is greyish-white on the anterior body and forewings, on the latter strewn with black and dusted brownish with black dots. Hindwings blackish-brown with light fringes. Expanse of wings: 20 mm. Jamaica.

30. Genus: **Lycomorphodes** Hmps.

Proboscis well-developed, palpi porrect, not extending beyond the forehead; antennae thickened by a cover of scales. Abdomen roughly haired. On the long, narrow forewings the venation is very similar to that

of *Ascaptesyle*; the two lower radial veins are either petioled or entirely coalescent; the 3rd subcostal vein rises farther towards the margin than the lowest, it may also be absent, and the uppermost anastomoses with the costal. On the hindwing the upper median vein is on a common pedicle with the lower radial. Numerous species, several of which strongly recall the smaller *Correbia*- or *Correbidia*-species from the family of the Amatids (*Syntomidae*).

L. bipartita Wkr. (34 e) differs from the similar forms by a big hair-tuft on the anterior tibiae. *bipartita*. The body is blackish-brown, on the vertex, collar and shoulder-covers striped orange; just so is the hairing of the abdominal base and of the anal tuft. Forewing bluish-black, in the basal half with an orange-yellow longitudinal streak and a distally dentate, light yellow, postmedian transverse band. The hindwing is yellowish in the basal half. Expanse of wings: 22 to 24 mm. Amazon.

L. hemicrocea Dogn. (34 d) is blackish-brown on the body and basal half of the forewing, with a *hemicrocea*. metallic blue lustre, the distal half of the forewing orange-red with a brown longitudinal stripe from the cell-end to the margin. Hindwings brownish with a faint blue reflection, towards the costal margin ochreous-yellowish. Expanse of wings: 22 mm. Colombia.

L. tortricina Roths. (34 d) has a yellow body, on the collar and shoulder-covers striped brown. *tortricina*. Forewings slightly reddish-yellow, with a reddish-brown, oblique longitudinal stripe near the base, and a discal shade being twice interrupted; margin likewise brown. Hindwing yellow, towards the margin brownish. Expanse of wings: 22 mm. Trinidad; Venezuela.

L. suspecta Fldr. (34 d) extremely resembles *bipartita*, on the body more bluish-black; shoulder- *suspecta*. covers not striped yellow. Hindwings almost quite black. Anterior tibiae without a hair-tuft. Expanse of wings: 20 to 22 mm. Brazil (Espírito Santo, São Paulo).

L. correbioides Schs. (32 m). Body brown mixed with yellow. Forewings yellow with a faded brown *correbioides*. median band and a broad brown margin. Hindwings unicolorously brown. Expanse of wings: 16 mm. Costa Rica.

L. aracia Jones (33 p). Head orange-yellow, on the forehead brown; thorax and abdomen chocolate- *aracia*. brown, on the shoulders striped yellow, anal tuft yellow. Forewings brown with an orange-yellow stripe at the base of the costal margin and a narrow, faded, postmedian transverse band which is interrupted on the discal fold and forms below it a dentiform projection outwards. Hindwings brown with a grey lustre. Costal margin yellowish. Expanse of wings: 18 mm. Brazil (São Paulo).

L. calopteridion Joan. (34 d). Body brownish-black, on the vertex, collar and shoulder-covers striped *calopteridion*. yellow. Forewings blackish-brown with an orange-yellow basal half of the costal margin; from the middle of the cell to the margin a dark stripe extends. Hindwings blackish-brown. Expanse of wings: 20 mm. Brazil (Novo Friburgo).

L. eptatra Schs. (34 d). Body bluish-black, on the vertex and prothorax spotted orange. Forewings *eptatra*. black with a leaden lustre and a short orange stripe at the subcostal base. Hindwings blackish-brown. Expanse of wings: 20 mm. French Guiana.

L. strigosa Btlr. (= fumata Mschlr.) (34 d). Body blackish-brown, on the vertex, collar and thorax *strigosa*. striped orange. On the orange-yellow forewing the base of the costal margin is striped black, the cell-spaces dusted brownish; the marginal third is profusely dusted black, on the two upper radial veins striped orange. Hindwings blackish-brown. Antennae particularly thickly scaled. Expanse of wings: 18 mm. Porto Rico; Brazil.

L. sordida Btlr. (= coccinea Drc.) (34 h) is orange on the head and thorax, on the forehead, collar *sordida*. and shoulder-covers striped black. Abdomen blackish with a yellow anal tuft. Forewings orange, in the marginal third scantily scaled blackish, often in the shape of small dentate spots. Hindwings orange with a blackish-brown distal- and proximal-marginal dusting, or also nearly quite darkened by blackish-brown. In the ♀ the yellow colour is more orange-red, on the middle of the costal margin with a bluish-black spot. Expanse of wings: ♂ 20 to 22 mm, ♀ 26 mm. Distributed from Mexico through Central America as far as Colombia.

L. dichroa Dogn. (34 e) is reddish-yellow on the head and thorax, forehead and abdomen are blackish. *dichroa*. On the reddish-yellow forewing the marginal area is black with a silvery lustre, the proximal bordering in the middle dentate. Hindwings brown. Expanse of wings: 20 mm. Colombia.

L. bicolor Roths. (34 e). Anterior body and forewings are yellow, with a dull orange lustre; forehead, *bicolor*. exterior margin of the collar, tips of the shoulder-covers, and abdomen are brownish-black. The forewing exhibits a blackish streak from the cell-end to the margin, which is darker in the ♀ and runs more obliquely. Hindwings blackish-brown. Expanse of wings: ♂ 16 mm, ♀ 22 mm. Colombia; Brazil (São Paulo).

L. splendida spec. nov. (34 e) is a magnificent larger species. Forewings and body with a blackish- *splendida*. blue lustre. Median and inner-marginal vein orange-red, the former towards the margin expanded like a wedge;

beyond the middle there is at the costal margin a very broad, orange spot being continued to the proximal margin as an indistinct transverse band; basal part in the submedian area likewise orange. Hindwing carmine-rosy, with a black apical spot extending narrowly to the anal angle. Collar and shoulder-covers orange. Described according to 1 fresh ♂ from the Rio Negro (Colombia) Coll. FASSL.

flavipars. **L. flavipars** *Hmps.* (34 e) is easily recognizable by the carmine hindwings; abdomen carmine. Head and thorax orange, striped brown; ventral side and abdominal end yellow. Forewings blackish-brown, proximal margin and a broad postmedian band orange. — In the form: **reducta** *form. nov.* (= ab. 1 *Hmps.*) (34 e) the forewings are preponderantly yellow suffused with scarlet, only a small stripe at the base of the costal margin and one on the median at the cell-end being blackish-brown, the apex of the abdomen being black in this form. Expanse of wings: 20 mm. Panama; West Colombia.

coccipyga. **L. coccipyga** *Dogn.* (34 h) is distinguished by the uppermost subcostal vein on the forewing terminating freely into the costal margin, and on the hindwing by the costal vein coalescing with the subcostal almost to the middle of it. Anterior body and wings are blackish-brown, intermixed with scanty silvery-white scales, and with a greenish lustre. Abdomen carmine, the apex and underside blackish-brown. Expanse of wings: 16 mm. Curacao.

circinata. **L. circinata** *Dogn.* (34 e) is a very small species with narrow wings. Anterior body and forewings blackish-brown, strewn with metallie green scales. Hindwings blackish-brown, towards the base lighter; abdomen likewise blackish-brown, the penultimate ring above carmine. Expanse of wings: 16 mm. Colombia (Rio Aguaca).

31. Genus: **Ascapesyle** *Dyar.*

Proboscis developed; the straightly porrect palpi slightly project beyond the forehead. On the forewing the two lower radial veins are longpetioled, the upper one rising from below the upper cell-angle. On the hindwing the middle radial is absent altogether, and the upper radial anastomoses with the subcostal. Differing from *Lycomorphodes* by the uppermost subcostal vein of the forewing running separately; besides, the lowest rises more towards the margin than the third from the second, and on the hindwing, the upper median and lower radial vein come unpetioled out of the lower cell-angle. Only 2 species known with dark forewings and purple, dark-margined hindwings.

submarginata. **A. submarginata** *Schs.* is reddish purple-brown on body and forewings, while the hindwings are carmine with a black marginal band. Expanse of wings: 22 mm. Trinidad.

purpurascens. **A. purpurascens** *Rothsch.* (34 e) is very similar, of a darker red-brown colour with a purple lustre. On the carmine hindwings the marginal band is red-brown and somewhat broader, ascending also at the proximal margin. Expanse of wings: 20 mm. Peru.

32. Genus: **Prolobosia** *Hmps.*

Proboscis developed; palpi long and slender, erected over the vertex; tibiae with long spurs. Forewing with a lobular projection of the costal margin before its middle, behind it with a slight indentation. Veins like in *Seripha*; but the upper radial vein rises from the upper angle, the 3rd subcostal vein is on a common pedicle with the two lower ones, and the uppermost ends separately. Hindwings almost the same as in the preceding, but the footstalk of the upper radial with the subcostal vein is much longer. The ♂ exhibits above on the submedian fold a hairy cover. Only 1 species:

schistacea. **P. schistacea** *Rothsch.* (34 e) is unicolorously brownish with a silvery bluish-grey lustre. Expanse of wings: 20 mm. Peru.

33. Genus: **Urozana** *Hmps.*

Very similar to *Seripha*; distinguished by much shorter palpi covered by a frontal hair-tuft. Antennae not thickened; on the forewing the middle radial vein rises above the lower cell-angle, otherwise the venation is exactly the same. The hindwing is extended into a long anal lobe, behind it the wing is somewhat concavely indented. Only 1 species:

cordatula. **U. cordatula** *Drc.* (34 h). Head and thorax black, with a coppery lustre; abdomen orange, on the 1st and 5th rings spotted black, ventral side black. Forewing purple brown, towards the margin striped dark green. Hindwing orange-red with a black apical spot. Expanse of wings: 22 mm. Guatemala.

34. Genus: **Seripha** *Wkr.*

Well characterized by the antennae being somewhat thickened in the middle, and by reverted subdorsal hair-tufts on the abdomen. Proboscis well developed, palpi short, porrect; posterior tarsi without any middle spurs. On the forewing the two lower radial veins rise from the lower cell-angle, the upper radial from below

the upper cell-angle; the 3rd subcostal vein is absent, the uppermost anastomoses with the costal. On the hindwing the upper median vein coalesces with the lower radial; the middle one comes almost from the middle of the transverse vein, and the upper radial is petioled with the subcostal vein.

S. pyrrhocrocis *Fldr.* (34 h) is unicolorously light metallic silvery blue, the hindwings somewhat more purple-blue; anal hairing and inner-marginal fringes of the hindwings in the ♂ orange; in the ♂ the anal angle is extended and long haired. Expanse of wings: 22 mm. Colombia. *pyrrhocrocis.*

S. coelicolor *Wkr.* is much smaller, the anal angle of the hindwing not extended. Expanse of wings: 18 mm. Venezuela. *coelicolor.*

S. plumbeola *Hmps.* (32 m) is quite unicolorously blackish-brown with a purple-grey lustre. Expanse of wings: 16 mm. Cuba; Ecuador. *plumbeola.*

35. Genus: **Nodozana** *Hmps.*

Proboscis developed, palpi anteriorly projecting beyond the forehead, antennae of the ♂ with eiliary peneils. On the forewing the median veins and lower radial veins rise separately from the lower cell-angle, the upper radial from below the upper angle; the ♂ is beneath roughly sealed on both wings. Hindwings like in *Neozana*, but the upper median and lower radial vein rise together from the same place in the lower cell-angle. 16 species, most of which have only been described in the last years.

N. thricophora *Hmps.* (= *polyzona* *Drc.* part., *lacteociliata* *Rothsch.*) (34 g) is distinguished by the hindwing beneath being below the cell provided with long-haired fringes, and by a hairy fold at the costal margin of the forewing beneath, terminating into a hairy knob in the middle of the costal margin. Forewing blackish-brown with 3 yellow spots, of which the postmedian costal-marginal spot is below spotted red. Abdomen and hindwing red, the latter with a black marginal band. Head and thorax are brown, vertex, collar, and shoulder-covers orange. Expanse of wings: 16 mm. Panama; Venezuela. *thricophora.*

N. boliviana *Rothsch.* (32 m) is considerably smaller and of a paler colouring, owing to its being thickly sealed white. The spots on the forewing are larger, the postmedian ones flown together to a band bordered by brown lines. Expanse of wings: 12 mm. Bolivia. *boliviana.*

N. coresa *Schs.* (= *prepielloides* *Rothsch.*) (34 g) greatly resembles *thricophora*, but the hindwings of the ♂ are beneath without any fringes. Colouring and marking otherwise almost the same, the postmedian spots confluent and forming in the ♀ a dentiform projection behind the red spot. Expanse of wings: 16 mm. Brazil (Amazon, São Paulo). *coresa.*

N. rhodosticta *Btlr.* (= *rubripuneta* *Rothsch.*) (34 g) is likewise very similar to the preceding, but the ♂ forewing is without the hairy fold and the knob; instead of it, the inner-marginal area of the hindwing is expanded and provided with long and rough scales and fringes. On the forewing the basal spot extends almost to the costal margin. Expanse of wings: 16 mm. Brit. Guiana (Orinoco); Surinam; Amazon. *rhodosticta.*

N. jucunda *Jones* (32 m). Head, collar, and tips of shoulder-covers light golden-yellow, thorax otherwise coppery brown; abdomen earmine. Forewings coppery brown with golden-yellow spots margined by dark brown: a large one in the basal area, extending from the proximal margin almost to the costal margin, and two flown together to a postmedian band, with a red discal spot in them. Hindwings earmine. Expanse of wings: 18 mm. Brazil (Santos). *jucunda.*

N. pyrophora *Hmps.* (34 g) is distinguished by numerous blackish-brown scent-seal spots on the underside of the forewing: one in the middle of the cell and one at the cell-end and behind it, a hairy spot below it, and fringes in the middle of the costal margin. Body and wings yellowish-white; the forewings exhibit a black discal spot and a large, orange-red spot in the middle of the wing, which is parted by a streak of the ground-colour from the cell-end to the proximal margin. Expanse of wings: 18 mm. Bolivia. *pyrophora.*

N. fifi *Dogn.* has only one large scent-spot in, behind and below the cell-end on the under surface of the forewing. Anterior body and forewings blackish-brown, head and collar, as well as the hindwings earmine, the latter with a broad black marginal band. Expanse of wings: 24 mm. Ecuador. *fifi.*

N. cocciniceps *Dogn.* differs by its almost quite red thorax; the forewings have a slight blue reflection, and the marginal band of the hindwing is narrower. Expanse of wings: 22 mm. Colombia. *cocciniceps.*

N. fifina *Dogn.* (34 f) likewise greatly resembles the two preceding, but it is smaller and of a more red-brown ground-colouring, on the forewings with a copper lustre; also the head and thorax are brown. The red hindwings are black-haired at the proximal margin. Expanse of wings: 20 mm. Panama. *fifina.*

N. xanthomela *Drc.* (34 f). Head, thorax, and the basal half of the forewing are orange-yellow, so is the basal half of the costal margin; abdomen, and rest of the wings black. Expanse of wings: 18 mm. Amazon. *xanthomela.*

N. bellicula *Schs.* (34 f) is a smaller insect with whitish forewings with a red cell-spot, a broad, greyish-brown, white-spotted median band and a black, oblique, postmedian band; from there to the margin the veins *bellicula.*

are striped black. Hindwings yellowish-red with a black apical spot. The anterior body is brown, mixed with white, the abdomen red, anteriorly more yellow. Expanse of wings: 14 mm. French Guiana.

- hieroglyphica*. **N. hieroglyphica** Rothsch. (34 f) is twice as large as the preceding. Head, thorax, and forewings light golden-yellow; abdomen and tips of the shoulder-covers red; at the base of the costal margin there is a small black spot, at the proximal margin a red one; 2 antemedian, parallel, curved, black lines, from the exterior one of which a black streak extends to the strongly curved posterior transverse line; before the margin another, oblique, black line; there are yet red spots at the cell-end and before the border at the costal and proximal margins. Hindwings red with a small black apical spot. Panama to Ecuador.
- bifasciata*. **N. bifasciata** Rothsch. (34 f). Anterior body and forewings golden-yellow, head, shoulder-covers and metathorax spotted coppery brown. Abdomen and hindwings scarlet, the latter with a minute apical spot. Forewings with 2 broad, black transverse lines suffused with a metallic blue; before and behind them the costal margin is likewise blackish-blue. Expanse of wings: 18 mm. Peru.
- picturata*. **N. picturata** Schs. (32 m) resembles *pyrophora* above, but the scent-spots beneath are entirely absent; the middle orange spot is much smaller, and before and behind it there are reddish-brown transverse lines. Hindwings of a pure white. Expanse of wings: 26 mm. Costa Rica.
- roseofuliginosa*. **N. roseofuliginosa** Rothsch. (34 f) looks like an *Illice*: anterior body and forewings blackish-brown; neck with red rings, collar white; abdomen above red with a brown dorsal stripe, beneath dark brown; forewing with 2 small, white, postmedian spots at the costal and proximal margins, the latter with a small continuation on the submedian fold, directed towards the base; at the base of the proximal margin a small red spot. Hindwings light carmine with a blackish-brown marginal band. Expanse of wings: 20 mm. Brazil.
- endoxantha*. **N. endoxantha** Jones (34 f) is a somewhat larger species with a brilliant orange-yellow body. The brownish-grey forewing exhibits a broad, orange inner-marginal stripe and a spot behind the middle of the costal margin. Hindwing orange with a rather broad, black marginal band. Expanse of wings: 24 mm. Brazil.

36. Genus: **Metalobosia** Hmps.

Differs from the multiform genus *Illice* by its shorter, porrect palpi. On the forewing the lower median vein rises nearer to the cell-end and is strongly curved, the uppermost subcostal vein anastomoses with the costal. Also on the hindwing the lower median vein is placed nearer to the cell-end; the upper one anastomoses with the lower radial vein, on the inner-marginal vein the hindwing of the ♂ is extended to a point. The abdomen shows thick hair-tufts towards the end. 11 pretty, small *Lithosiinae* are reckoned hereto, with dark forewings and mostly dark red, black-margined hindwings.

- antras*. **M. antras** Dogn. (= *posteaerulescens* Rothsch. ♀, nec ♂) is on the anterior body and forewings metallic golden green, in the ♀ bluish-green. Hindwings and abdomen blackish-brown, the latter with yellow hair-tufts. On the hindwing the ♂ exhibits beneath, above the inner-marginal vein, like in the 4 following species, a fold set with roughly sealed fringes. Expanse of wings: 24 to 30 mm. Ecuador, Peru.
- ducalis*. **M. ducalis** Schs. (34 f). Head, thorax, and forewings are blackish-brown, with a metallic green lustre; the upperside of the posterior femora and long hair-tufts on the posterior tibiae are pink. Abdomen carmine with a black apex and long, white hair-tufts on the 4th ring. Hindwings deep carmine with a blackish-brown marginal band. Expanse of wings: 18 mm. Costa Rica.
- postflavida*. **M. postflavida** spec. nov. (34 b) has, like *ducalis*, in the lobular proximal margin of the hindwing beneath, fringes of long yellow scaly hairs; besides the cell is covered with scent-scales. Forewings and anterior body unicolorously brown with a brassy lustre. Hindwing yellow with a small, black apical spot; abdomen above yellow, beneath blackish-brown like the legs. Described according to a ♂ from the Rio Negro (Colombia) from the Coll. FASSL.
- chalcona*. **M. chalcona** Dogn. (34 f). Head and thorax blackish with a bronze-green lustre, the forewing more silvery-green, at the base golden-brown. Abdomen and hindwing blackish-brown, the former with a metallic green reflection. Only 1 ♀ known. Expanse of wings: 20 mm. Colombia.
- elis*. **M. elis** Drc. (34 b) is unicolorously blackish-brown, with a slight purple lustre, the hindwings somewhat lighter brown. The abdominal hair-tufts are orange. The ♀ exhibits a bronze-green lustre in the inner-marginal half of the forewing and on the thorax. Expanse of wings: 24 mm. Guatemala, Brazil.
- holophaea*. **M. holophaea** Dogn. (34 h) has on the hindwing a deep indentation before the extraordinarily large, long fringed anal lobe, and exhibits in the cell beneath a black scent-scale spot and behind it grey scent-scales. Body and wings are blackish-brown, the latter with a green metallic lustre. Expanse of wings: 20 mm. Colombia.
- varda*. **M. varda** Schs. (34 b), like the following species, is without any fringes above the inner-marginal vein of the hindwing. Anterior body and forewings blackish-brown with a coppery and purple lustre. Abdomen

above red, beneath black; hindwings carmine, towards the proximal margin more orange with a black marginal band. Expanse of wings: 22 mm. Brazil.

M. invarda Schs. (34 b) differs by the considerably broader black marginal band of the hindwing; *invarda*. the red abdomen exhibits on the 1st ring a purple brown dorsal spot, of the same colour are the two last rings and the underside. Expanse of wings: 20 mm. French Guiana.

M. postrubida Roths. is larger, with narrower forewings exhibiting a metallic blue lustre, like the *postrubida*. whole body does. Hindwing red, with a black marginal band, proximal margin and basal part. Expanse of wings: 26 mm. Colouring similar to that of *Nodozona cocciniceps*, *Ascapterys purpurascens*, *Talara lepida* etc. Panama.

M. atriloba Dogn. (34 b) has a still broader black inner-marginal area. Body and forewings of a *atriloba*. plain blackish-brown. Expanse of wings: 18 mm. Colombia.

M. cuprea Schs. (34 b). Head and thorax dark greyish-brown, abdomen carmine, at the base more *cuprea*. orange, beneath black. Forewings coppery golden, hindwings pink, with a brown apical spot. Expanse of wings: 24 mm. Brazil.

M. similis spec. nov. (34 b) looks entirely like *postflavida* described above, but it has narrow hindwings *similis*. without any scent-distinctions and a scarcely extended anal angle, but instead the abdomen, on the first ring, exhibits lateral yellow hair-tufts. The colouring is exactly like there, but the abdomen is also above blackish-brown, and the hindwing exhibits a black marginal band. Described according to 2 ♂♂ from the Rio Negro (Colombia) from the Coll. FASSL.

M. diaxantha Hmps. (34 g) is a deviating species in which the ♂ has no extended anal angle of the *diaxantha*. hindwing. Forewing brown with a coppery lustre and with a long, irregular, yellowish-white longitudinal stripe. Hindwing brown, only at the base pink. The anterior body is brown with a coppery lustre; the only specimen known is destitute of its abdomen. Expanse of wings: 14 mm. Amazon.

37. Genus: **Neozana** Hmps.

Proboscis developed; the slender, porrect palpi project beyond the forehead. Antennae of the ♂ at the base thickened by accumulated scales, ciliated. Forewing narrow with a round apex, in the veins not different from *Arhabdosia*, except the uppermost radial vein rising from the upper cell-angle, not from below it. On the hindwing the middle radial is present, the upper one rises on a long pedicle with the subcostal vein. Only 1 species:

N. germana Roths. (34 g). Head and thorax light yellow, abdomen carmine, anteriorly and *germana*. posteriorly yellow. Forewings light golden yellow, with yellow spots and stripes; hindwing light red, at the costal margin yellowish, with a small black apical spot. Expanse of wings: 18 mm. Peru.

38. Genus: **Arhabdosia** Dyar.

Distinguished from *Metalobosia* by still shorter palpi; on the forewing the upper median and lower radial vein rise from the same place, whilst on the hindwings they are petioled; the middle radial is absent, the upper one anastomoses with the subcostal vein. Only 1 species:

A. subvarda Schs. (34 h) is dull brown on the anterior body and forewings; abdomen and hindwings *subvarda*. are carmine, the latter with a black marginal band. Expanse of wings: 20 mm. French Guiana.

39. Genus: **Illice** Wkr.

A very numerous genus of small, often very similar species, mostly marked yellow and red. Proboscis well developed; palpi slender, erect, not extending as far as the vertex. On the forewing the upper median vein rises before the lower angle, the middle radial above it; the upper radial from above the upper angle; the 3 lower subcostal veins are petioled, the two upper ones terminate separately into the costal margin. On the hindwing the upper median vein rises close at the cell-angle, the middle radial above it; the upper one is petioled with the subcostal. The larvae, as far as they are known, exhibit long hairs on tubercles, and live on lichens.

I. sexalata spec. nov. (33 a) is greatly distinguished by the inner-angular lobe being split as far as *sexalata*. the base. Forewings with a blackish-blue lustre. Median and its branches orange; behind the middle an indistinct, ochreous-yellow band, at the costal and proximal margin of a brighter orange. Hindwing carmine-rosy with a black apical spot and anal lobe. Head and thorax blackish-blue, vertex, collar, and shoulder-covers striped orange; abdomen carmine with very long, orange-yellow hair-tufts on the dorsum of the first abdominal rings. 1 ♂ from the Rio Songo (Bolivia) (FASSL).

I. dives Schs. (33 a). The ♂ has, like in the following species, the proximal angle of the hindwing *dives*. extended very long in the shape of a lobe. Anterior body brown, abdomen carmine, collar, chest and legs yellow.

Forewings purple brown with a golden lustre; beyond the middle 2 yellow spots at the costal and proximal margins, which may flow together to a transverse band. Hindwing carmine, in the costal part light-yellow with a broad, blackish-brown marginal band; fringes orange. The ♀ has only a triangular spot at the proximal margin. Expanse of wings: 20 mm. Brazil.

- mediofasciata*. **I. mediofasciata** Rothsch. (33 a) differs from *dives* by its carmine (not yellow) chest and legs, the marginal band of the hindwing being narrower; the ♀ also has on the hindwing a complete transverse band somewhat strangulated in the middle. Expanse of wings: 18 mm. Bolivia.
- trimaculata*. **I. trimaculata** Jones (33 a) is much smaller. The collar is orange, the shoulder-covers light-yellow, the ventral side orange-yellow. The forewing shows 2 separate spots beyond the middle, and a longitudinal spot at the proximal margin near the base. Hindwing pink, on the submedian fold yellowish, only the apex being brown. Expanse of wings: 16 mm. Brazil: Castro (Paraná).
- fasciata*. **I. fasciata** Schs. (34 h). A considerably larger species, distinguished by its yellow abdomen and hindwings. The forewings marked like in the preceding, the 2 postmedian spots separated or confluent to a transverse band. Anal-angular lobe and fringes there particularly long and dark brown. The ♀, like in *dives*, has only a triangular inner-marginal spot. Expanse of wings: 26 mm. Brazil: Castro, São Paulo.
- endoxantha*. **I. endoxantha** Hmps. (33 a) greatly resembles the preceding, the 2 spots of the forewing separated, abdomen and hindwings orange, the latter towards the costa of a purer yellow; before the anal-angular lobe the hindwing shows a deep indentation. Expanse of wings: 24 mm. Brazil.
- schwarziorum*. **I. schwarziorum** Dyar (33 a) initiates a group in which the ♂ has a slightly, though still distinctly extended anal angle of the hindwing. The forewing shows a longitudinal band at the proximal margin near the base, and a postmedian transverse band being spotted carmine at the proximal margin. Expanse of wings: 20 mm. Mexico.
- triplaga*. **I. triplaga** Hmps. (33 a) greatly resembles the preceding by reason of the head, collar, and shoulder-covers being light yellow; the forewings much darker blackish-brown, in *schwarziorum* more silky grey, the postmedian spots separated, the lower one likewise with a carmine touch. On the hindwing the marginal band extends farther to the proximal angle. Expanse of wings: 20 mm. Paraguay.
- unifascia*. **I. unifascia** Grt. (33 a) is orange-yellow on the head and thorax. On the blackish-grey forewing, the basal inner-marginal spot is orange; it is confluent with the narrow transverse band being widened at the costal and proximal margins. Hindwings carmine with a very variable marginal band. The species is extremely variable. In the typical form the yellow thorax exhibits a blackish-brown median spot which is absent in *texensis mexicana* nom. nov. (= ab. 1 Hmps.). — In f. *mexicana* nom. nov. (= ab. 2 Hmps.) from Mexico the basal inner-marginal spot is not connected with the transverse band. — In the form: *tenuifascia* Harvey from Texas the transverse band is very narrow, while in the form: *kentuckiensis* Dyar from Kentucky it occupies a whole third of the wing and is broadly confluent with the basal spot at the proximal margin; the marginal band is here very narrow.
- interrupta*. — **I. interrupta** nom. nov. (= ab. 4 Hmps.) (33 a) from Alabama has the transverse band separated into two spots; *barnesii*. — the same is the case in the form: *barnesii* Dyar from Colorado, in which the whole anterior body is not yellow or orange, but grey; only the interior margins of the shoulder-covers and the base of the collar are yellow. The hindwings in this form may also be orange or yellow. The otherwise typical form with purely yellow hindwings may be denominated: *flava* nom. nov. (= ab. 6 Hmps.). — *perrosea* Dyar is the form from California (Los Angeles), in which the whole anterior body and also the transverse bands of the forewings exhibit a carmine-rosy colouring. — Finally there has been found another form: *flavicosta* nom. nov. (= ab. 5 Hmps.), in which the whole costal margin, from the base to the apex, is yellow, only one inner-marginal spot being present behind the middle. Expanse of wings: 18 to 24 mm. Distributed through the whole of North America as far as Mexico and Yucatan.
- angelus*. **I. angelus** Dyar (33 a) has more stretched forewings of a light slate-coloured lustre; the yellow transverse band is uniformly broad, somewhat oblique, and flows together with the inner-marginal band. Anterior body yellow, abdomen pink like the hindwings, exhibiting a grey apical band. Expanse of wings: 23 to 28 mm. Arizona, Mexico.
- hilaris*. **I. hilaris** Fldr. (33 b) has only yellow palpi, forehead and collar, whilst the rest of the anterior body is blackish-brown. Forewings purple brown with a golden-yellow spot at the base of the proximal margin, and a broad, straight, transverse band; fringes towards the apex yellow. Hindwings carmine with a dark brown costal margin growing narrower towards the margin. Expanse of wings: 18 mm. Venezuela.
- abala*. **I. abala** Schs. (32 n) is very similar, still smaller; the yellow postmedian band is slightly curved. Hindwings with a broader marginal band. Expanse of wings: 16 mm. French Guiana.
- discistriga*. **I. discistriga** Dogn. (33 b) is well characterized by the yellow wedge-shaped spot on the discal fold towards the margin; moreover larger than *abala*, hindwing very broadly bordered with a blackish brown; shoulder-covers and collar striped yellow, the thorax otherwise dark brown; apex of abdomen and underside blackish-brown. Expanse of wings: 20 mm. French Guiana.
- metoxia*. **I. metoxia** Hmps. (34 g). Head and thorax blackish-brown, vertex and collar orange-yellow like the palpal base and the dark banded legs; abdomen above carmine, beneath yellow. Forewings blackish-brown

with an orange-yellow spot at the base of the proximal margin, next to the base spotted red; at the anal angle a round spot likewise marked red; the median and its branches striped yellow; costal margin from the middle to the apex, and the distal margin yellow. Hindwings blackish-brown, only in the inner-marginal area carmine. Expanse of wings: 16 mm. St. Vincent; Grenada.

I. phaeiceps *Hmps.* (= *unifascia* *Drc.*, nec *Grt.*) (32 n) has only one large orange spot near the proximal margin; the blackish-brown forewings exhibit besides only a narrow orange stripe at the base of the proximal margin. Abdomen and hindwings carmine, the latter bordered with black, but not as far as the anal angle. Head and thorax, blackish-brown. Expanse of wings: 16 mm. Mexico (Presidio). *phaeoceps.*

I. subrubra *Schs.* (32 n) is unicolorously olive-brown on the anterior body and forewings; palpi, hindhead, and collar are carmine like the abdomen; of the same colour are the hindwings with a blackish-brown apical spot. Expanse of wings: 16 mm. French Guiana. *subrubra.*

I. longistriga *Rothsch.* (33 b). Head and thorax white, mixed with brown; collar and abdomen carmine-rosy. Forewing white, mixed with reddish-brown, on the submedian fold and proximal margin purely white. Hindwing carmine-rosy with a blackish-brown apical spot. Expanse of wings: 14 mm. Peru. *longistriga.*

I. biota *Dyar* (33 b) is very similar, larger; distinguished by yellowish collar and shoulder-covers. Forewing more slate-coloured with a yellowish-white streak on the submedian fold, which is red in the ♀ like the hindhead and collar. Expanse of wings: 18 mm. British Guiana. *biota.*

I. polyzona *Drc.* (33 b) is a more common, widely distributed species with a whitish head and thorax; the blackish-brown forewing exhibits a yellowish-white, rosy tinted spot at the base of the proximal margin, a quadrangular costal-marginal spot and a triangular inner-marginal spot behind the middle, being often flown together to a band: *conjuncta* *form. nov.* Hindwings light carmine with a black apical spot. Expanse of wings: 16 mm. From Mexico to Brazil (Rio de Janeiro); Dominica. *polyzona.* *conjuncta.*

I. subrufa *Bs. & Mc D.* (32 n) is light ochreous-yellow on the head, collar, and shoulder-covers; the rest of the thorax is greyish-brown; abdomen carmine-rosy. Forewings yellow, thickly dusted brown with a yellowish-white spot at the base of the proximal margin and 2 triangular postmedian spots. Hindwings light pink with a blackish-brown apical spot. Expanse of wings: 14 mm. Texas. *subrufa.*

I. pygmaea *Schs.* (32 n). One of the smallest species, with a blackish-brown head and thorax; vertex, collar and shoulder-covers whitish. On the greyish-brown forewings the transverse band is somewhat strangulated in the middle; along the base of the proximal margin there is a broad whitish spot. Hindwings yellowish-pink with a blackish apical spot. Abdomen carmine. Expanse of wings: 12 mm. French Guiana. *pygmaea.*

I. rosacea *Schs.* (34 i) initiates the species in which the anal angle of the hindwing is not extended. Distinguished by long hair-tufts on the last abdominal rings and very easily recognizable by the carmine-rosy forewings being dusted brownish-grey only towards the proximal margin. Anterior body grey, collar and abdomen carmine. Expanse of wings: 22 mm. Brazil (São Paulo). *rosacea.*

I. subjecta *Wkr.* (33 b). Head and thorax blackish-brown; vertex, collar and shoulder-covers partly carmine like the upperside of the abdomen; the latter beneath brown. Forewing blackish-brown with a carmine submedian fold and proximal margin as far as the large, red, inner-marginal spot beyond the middle; costal margin likewise pink as far as a small postmedian spot. — In forma: **packardii** *Grt.* this latter spot is much larger and round. Hindwing carmine with a blackish-brown apical spot. Expanse of wings: 20 mm. Widely distributed in the United States from New York to Texas. — The larva is grey, watered black, with a white spotted band across the dorsum, and a black, undulate lateral line; blackish hairs on orange tubercles. It lives on lichens of oaks from October to April. *subjecta.* *packardii.*

I. xanthospila *Hmps.* Thorax and forewings brown, head, collar, shoulder-covers, and abdomen carmine. At the proximal margin of the forewing an orange longitudinal band being confluent with the postmedian spot; at the costal margin behind the middle a second spot. Hindwings likewise brown, with a red base. Expanse of wings: 24 mm. Brazil. *xanthospila.*

I. injecta *Dyar* (33 b) differs from the other species by a yellow costal-marginal streak; the slate-coloured forewing exhibits besides a triangular inner-angular spot which is connected with an inner-marginal spot extending as far as the base. Anterior body yellow, or pink, on the thorax mixed with grey. Abdomen and hindwings pink, the latter with a grey apical spot. — f. **gamma** *Dyar* is without the yellow costal-marginal streak, and has a broader marginal band of the hindwing. Expanse of wings: 18 to 22 mm. North America. *injecta.* *gamma.*

I. striata *Ottolengui* (33 b) is a larger species, with grey forewings being lighter striped in the cell-spaces; costal and proximal margins narrowly pink, on the latter beyond the middle a small spot. Anterior body brownish-grey; neck, ends of shoulder-covers, and abdomen pink like the hindwings; the latter show a large, brownish-grey apical spot which, however, may also be very much smaller. f. **costimacula** *nom. nov.* (= ab. 2 *Hmps.*) exhibits besides a wedge-shaped costal-marginal spot. Expanse of wings: 20 to 26 mm. Florida, Colorado. *striata.* *costimacula.*

I. roseiceps *Hmps.* (33 c) is a larger species, with about the same colours and markings as *angelus*, *roseiceps.*

though the head, collar, and shoulder-covers are carmine and the postmedian spots both separated. The hindwings are red, turning yellow towards the apex. Expanse of wings: 24 mm. Paraguay.

- flagrans.* **I. flagrans** Hmps. (32 n) Head and thorax deep orange. Forehead and shoulder-covers black, abdomen pink. Forewing blackish-brown with an orange-yellow inner-marginal band being expanded to a conical spot near the proximal angle. Hindwing yellowish-scarlet with a broad marginal band. Expanse of wings: 18 mm. Argentina.
- calochroma.* **I. calochroma** Snell. (33 c) somewhat resembles *biota* in its colours and scheme of markings, but the light yellow stripe is not situate on the submedian fold, but along the proximal margin, and terminates rather abruptly before the anal angle. Expanse of wings: 24 mm. Argentina.
- rhodoeraspis.* **I. rhodoeraspis** Hmps. (32 n) has quite unicolorously greyish-brown forewings, only the extreme costal margin being narrowly red. Head and thorax greyish-brown; palpi, collar, chest and the greatest part of the legs carmine like the abdomen. Marginal band of the hindwing narrow. Expanse of wings: 16 mm. Argentina.
- minuta.* **I. minuta** Btlr. (33 c) entirely resembles *biota*, but it has a much more extensive apical spot of the hindwing, and the submedian streak of the forewing does not grow narrower towards the margin. Expanse of wings: 16 mm. Colombia.
- griseola.* **I. griseola** Roths. (33 c) is brownish-white on the head and thorax; the collar is carmine-rosy like the abdomen. The forewings are brownish-white, towards the proximal margin of a purer brown. Hindwings carmine with a greyish-brown marginal band. Expanse of wings: 18 mm. Brazil (Rio de Janeiro, Minas Geraes).
- bisigna.* **I. bisigna** Berg (33 c). Anterior body and ventral side are brownish-grey, mixed with white, collar yellow, abdomen carmine. Forewings brownish-grey, strewn white with 2 white postmedian spots at the costal and proximal margins. Hindwings pink with a grey marginal band. Expanse of wings: 20 mm. Patagonia.
- plumbea.* **I. plumbea** Stretch. (33 c). Anterior body and forewings brownish-grey, dusted white; the latter with a triangular white spot near the proximal angle. Abdomen carmine, beneath grey. Hindwings brownish-grey with a red spot in the inner-marginal half. Expanse of wings: 22 mm. Texas.
- rubricollis.* **I. rubricollis** Schs. (33 c) has unicolorously dull olive-brown forewings, the hindwings as in *plumbea*. The anterior body is blackish-brown; collar and abdomen carmine. Expanse of wings: 16 mm. French Guiana.
- tyres.* **I. tyres** Drc. (33 c). Anterior body and forewings grey, strewn with black, abdomen pink. Forewing with a black antemedian line between the cell and proximal margin, forming an angle on the inner-marginal vein; a postmedian, irregular, white band, being on both sides dentate below the costal margin, and towards the proximal margin proximally faded; before the margin darker nebulous spots. Hindwing pink with a black apical spot. Expanse of wings: 22 mm. Guatemala, Nicaragua.
- ditrigona.* **I. ditrigona** Schs. (33 d). Body orange with bluish-black spots on the forehead, shoulders and thorax. Forewings orange, densely strewn with a purple brown, with 2 orange longitudinal stripes in the basal part, and 2 triangular, postmedian spots almost touching each other. Hindwing orange with a black apical spot. In the ♀ the ground-colour is darker, the stripes and spots lighter yellow, the latter more separated. Expanse of wings: 20 mm. Brazil (Novo Friburgo).
- blanda.* **I. blanda** Jones (32 n) is somewhat similar, but the head and thorax are chocolate-brown, only the vertex, ends of shoulder-covers, and metathorax are yellow. On the forewing, in the basal part, there is a large, golden-yellow spot, the postmedian spots are united to a transverse band. Hindwings like in *ditrigona*. Expanse of wings: 22 mm. Brazil (Santos).
- lycomorphodes.* **I. lycomorphodes** spec. nov. (33 d) has a black body and forewing, the latter particularly in the marginal area strewn with scales of a silvery blue; at the base of the costal margin a deep-yellow spot, and behind the middle, a similar transverse band projecting in the middle pointedly towards the margin. Hindwing yellow with a black marginal band. Legs black with a whitish first tarsal joint. Described according to a ♂ from the Rio Songo (Bolivia) from the Coll. FASSL.
- persimilis.* **I. persimilis** Hmps. (33 c). Head, collar, and spots on the shoulder-covers are yellowish-white, forehead and thorax purple brown. Underside and abdomen yellow like the hindwings, the latter with a small brown apical spot. Forewings purple brown with 3 yellowish-white spots: in the ♀ the posterior spot of the costal margin is absent, and the under surface is dusted red. Expanse of wings: 22 mm. Brazil (Rio de Janeiro).
- cryptopyra.* **I. cryptopyra** Hmps. (33 d) differs from *persimilis* by its orange-yellow head and collar, with red abdomen and hindwings, the latter with black fringes. The forewings are marked the same, though more orange. Expanse of wings: 24 mm. Brazil.
- triplagiata.* **I. triplagiata** Roths. (33 d) likewise greatly resembles the preceding, but the head and thorax are yellowish-white, on the forehead and metathorax spotted black. Abdomen above red, beneath yellow. The forewings exhibit a slight grey lustre, and the yellowish-white spots are bordered with black. Hindwing with a black apical spot. Expanse of wings: 20 mm. Mexico.

I. petrovna Schs. (33 d). Head and thorax grey and black, collar and 2 spots in the neck yellow, abdomen orange. Forewings grey, on the veins striped black, near the base with a faded white band; in the middle there is a white band bordered with black, with small black discal spots in it, growing somewhat broader above and below the middle; a large white subapical spot and several small, dentate, antemarginal spots. Hindwings yellowish-white with a blackish-brown margin growing much broader towards the apex. Expanse of wings: 24 mm. Brazil.

I. nexa Brd. (= grisea Pack., deserta Fldr.) (33 d) is greyish-brown on the anterior body, with a yellowish white vertex and collar. Abdomen light yellowish. Forewings blackish-grey with a basal, light yellow inner-marginal spot and a slightly oblique postmedian band not reaching the costal margin and being a little strangled on the submedian fold. Hindwing light yellow with a large, blackish-brown apical spot. Expanse of wings: 22 mm. North America, California.

I. dorsimacula Dyar (33 d) is sandy grey on the anterior body and forewings, the latter with a small, dirty white spot near the proximal angle and a very small one above it in the middle. Hindwings and abdomen yellowish, with a rosy tint; hindwing with a dark marginal band. Expanse of wings: 20 mm. California.

I. liberomacula Dyar (33 d) is quite similar, but the forewings have, behind the lower cell-end, a double, silvery white spot, above which white dots extend as far as the costal margin. Abdomen and hindwings of a more dirty yellow. Expanse of wings: 17 to 19 mm. California (Los Angeles).

I. batialis Wkr. (= stupidalis Wkr.) (33 d) is an entirely different, larger animal. Body strewn with a greyish black like the forewings; the latter exhibit 2 irregularly dentate, antemedian and postmedian transverse lines, a darker antemarginal undulate line, and a row of dots on the margin. Abdomen and hindwings whitish, the latter darkened at the apex. Expanse of wings: 25 to 32 mm. Brazil (Rio de Janeiro, São Paulo).

I. faustinula Brd. (= fusca Stretch.). Light greyish-brown, on the forewings strewn with darker scales; a postmedian transverse band of a lighter grey, growing broader at the proximal margin, above it twice strangled. Hindwings somewhat lighter. Expanse of wings: 24 mm. California. — Larva blackish, head green, spotted black; across the dorsum a reddish-yellow line bordered with grey and black; black subdorsal lines interrupted by grey, and grey lateral bands; on yellow tubercles long blackish hairs being banded grey below the lateral stripes. It lives on lichens and pupates in a silky cocoon interwoven with hair. As *nexa* was bred from the same larvae, it is probably only a form of it.

I. orbonella Hmps. (33 e) is unicolorously light greyish brown on the anterior body and forewings. Neck, collar, abdomen, and hindwings orange, the latter with a black marginal band. Expanse of wings: 24 mm. Brazil (Castro; Rio de Janeiro).

I. citrina Drc. (33 e) is very well distinguished by the light golden green colour of the anterior body and forewings; forehead, vertex, shoulders, and metathorax spotted black; the forewings exhibit 2 black, dentate, antemedian and postmedian transverse stripes, from the postmedian stripe, on the middle radial, a stripe branches off to the margin. Costal margin at the base and before the apex black, so are the fringes. Abdomen and hindwings orange, the latter with a black apical spot. Expanse of wings: 20 mm. Panama. — In the form *intacta* Roths. from Peru the apical spot on the hindwing is continued as far as the inner-marginal vein as a black marginal band.

I. tessellata Dogn. (33 e). Head and thorax yellowish-white; vertex spotted brown, collar and shoulder-covers bordered with brown; abdomen yellow. Forewings golden lustrous white with 2 brown transverse lines, the distal one of which is expanded in the middle, where it encloses a white spot; both are connected by a brown longitudinal stripe continued to the margin; costal margin at the base and before the apex brown, like the fringes. Hindwing yellow, with a brown apical spot. Expanse of wings: 16 mm. Colombia: from the Rio Dagua.

I. opulentana Wkr. (33 p). Palpi and forehead of a deep blue; vertex and collar metallic green, thorax golden yellow, anteriorly with a blue spot; abdomen yellowish-white, with lateral, orange hair-tufts. Forewings golden yellow with a dark blue antemedian band, composed of 3 wedge-shaped spots, at the lower cell-end a small blue spot. Hindwing yellowish-grey with a dark marginal band. Expanse of wings: 20 mm. Amazon, Bolivia.

I. croesus Hmps. (= opulentana Hmps. ♀, nec ♂) (33 e) differs from *opulentana* by its pale carmine abdomen and hindwings; the forewing exhibits in the ♂ a complete blue transverse band also behind the middle from the upper median vein to the proximal margin, in the ♀ only 2 spots; in the latter the marginal band of the hindwing is broader. Expanse of wings: ♂ 16 mm, ♀ 20 mm. Espiritu Santo; Colombia (Muzo).

I. ruficollis Schs. (= deceptans Dyar) (33 e) is an entirely one-coloured, small, brownish-black insect with a slight blue reflection; the first palpal joint, hindhead, and collar are orange. Expanse of wings: 22 mm. Brazil (São Paulo, Castro [Paraná]).

40. Genus: **Prepiella** Hmps.

Proboscis developed; palpi rather short, porrect. Antennae of the ♂ combed or ciliated. Spurs of tibiae of medium length. On the forewing the upper median vein rises before, the middle radial vein above

the cell-angle, the upper radial below the upper cell-angle; the uppermost subcostal vein approaches the costal, but does not anastomose with it. On the hindwing the upper median and lower radial veins are on a long footstalk, or they are entirely coalescent; the middle radial comes from above the cell-angle, the upper radial is petioled with the subcostal. The genus contains about a dozen forms distributed over Tropical America; most of them have only recently become known.

- hippona*. **P. hippona** Drc. (33 c) is dark brown on the anterior body and forewings, with a purple and coppery reflection. Abdomen orange-red, with long orange hair-tufts on the sides of the 3rd segment, the last ring brown. Hindwing red with a dark brown apical spot. Expanse of wings: 20 mm. Guatemala.
- phoenicolopha*. **P. phoenicolopha** Hmps. (32 n) is dark brown on its head and thorax with a blue reflection; abdomen of a lighter brown, the 3rd and 4th rings and lateral hair-tufts carmine. Forewings dark brown; hindwing carmine, with a dark brown marginal band. Expanse of wings: 14 mm. Ecuador.
- procridia*. **P. procridia** Hmps. (33 e). Head and thorax blackish-brown, with a metallic green reflection; abdomen blackish-brown, beneath green; the lateral hair-tufts on the 3rd ring yellowish-red. Forewings blackish-brown; at the border and costal margin suffused with golden green. Hindwings dark brownish-grey, the anal-angular lobe haired reddish-yellow. Expanse of wings: 20 mm. Paraguay.
- miniola*. **P. miniola** Hmps. (34 i). Body orange, on the abdomen above carmine. Forewings orange, with black vein -streaks in the basal and marginal areas, and 2 black, dentate, antemedian and postmedian lines. Hindwings carmine with a black marginal band. Expanse of wings: 14 mm. Amazon. — In Peru there flies
- peruana*. **peruana** form. nov. (= ab. 1 Hmps.) in which the sharp tooth outside of the anterior transverse line is absent on the median.
- strigivenia*. **P. strigivenia** Hmps. (33 e) resembles *miniola* in the marking, but the ground-colour is yellow, only in the discal area there is a line-shaped, carmine marking. Hindwings with a slight carmine tinge. Expanse of wings: 16 mm. Amazon (Ega).
- convergens*. **P. convergens** Schs. (33 e). By its larger size it differs from the preceding. Abdomen more pink. Anterior body and forewings light isabel-coloured; the forewings in the basal and marginal halves on the veins striped black; in the middle of the proximal margin rises a black line turning round the cell-end and ending again at the proximal angle; it encloses a light yellow area, with a red spot in the cell-end and some red dusting in the submedian space. Hindwing yellow with a black apical spot. Expanse of wings: 18 mm. French Guiana.
- pexicera*. **P. pexicera** Schs. (33 e) resembles *strigivenia* (33 e), but it has combed antennae, the body and forewings being of an ochraceous yellow with a similar marking; anterior and middle transverse lines are connected by a black streak; at the cell-end there is a red spot. Hindwing carmine with a black apical spot. Expanse of wings: 14 mm. Venezuela.
- radicans*. **P. radicans** Hmps. (= *strigillata* Roths.) (32 m). Head and thorax yellow; abdomen likewise, but above with a carmine tint. Forewings bright yellow, with red stripes on the cell-fold and submedian fold, the marginal area suffused with red. Basal area like in the preceding striped black, behind it a black antemedian line; the posterior transverse line is irregular, running from the costal margin obliquely to the marginal line on the lower radial, then returning as far as below the cell-end near the anterior line, then again bent outwards; marginal area in the upper half with black veins; an antemarginal curved line. Hindwings yellow, with a slight carmine tint. Expanse of wings: 16 mm. British Guiana.
- aurea*. **P. aurea** Btlr. (33 f). Body orange-yellow, on the venter with black bands. Forewings golden yellow, with a similar bluish-black marking as the preceding, and a carmine cell-spot. Hindwing carmine, with a black apical spot being in the ♀ prolonged to a marginal line. Expanse of wings: 14 mm. Venezuela; Amazon.
- sesapina*. **P. sesapina** Btlr. (33 p) resembles *aurea*, and is of a paler yellow, the abdomen above tinged red. It differs by the very strongly dentated anterior transverse line; the red median spot is generally absent, whilst
- rubripunctata*. in — **rubripunctata** form. nov. (= ab. 1 Hmps.) from Bolivia it is present. Hindwings carmine with a small brown apical spot. Fringes brown, at the proximal angle orange. Expanse of wings: 16 mm. Brazil (Espírito Santo); Bolivia.

41. Genus: **Chionosia** Hmps.

Proboscis developed; palpi slender, erect, not reaching the vertex. ♂ antennae ciliated. Veins similar as in the preceding genus, but the upper radial vein is petioled with the lower subcostal veins, the 3rd subcostal vein being absent; the middle radial vein is mostly also removed down as far as the cell-angle. On the hindwing the middle radial is absent, the rest like in *Prepiella*.

- apicalis*. **Ch. apicalis** Z. (36 d) is white, with an olive-yellowish tinge. The forewings are traversed by darker olive bands, the posterior one of which makes a large bow round a black discal spot; before the apex another oblique brown streak and below it one at the margin. Hindwings white with a small, brownish-grey subapical spot. Expanse of wings: 18 mm. Rio de Janeiro. — subsp. nov. **trinitatis** (= subsp. 1 Hmps.) is of a purer white, with a slight yellow tint. Trinidad.
- trinitatis*.

Ch. zonata *Hmps.* (32 m) somewhat resembles *apicalis*, but it is tinted more brownish, and the transverse bands are flown together to a very broad, brownish-grey median band bordered by somewhat darker lines. Expanse of wings: 16 mm. Surinam.

42. Genus: **Lamprostola** *Hmps.*

Very much like *Prepiella*. The palpi are longer, erect, the terminal joint pointed. Abdomen with long, lateral hair-tufts towards the end. Veins of the forewings like there, but on the hindwing the upper median vein and lower radial vein anastomose, the middle radial rising with them from the lower cell-angle.

L. aglaope *Fldr.* (= *hercyna Drc.*) (33 f). Head and thorax black, anal tuft and ventral side likewise black, the rest of the abdomen is above scarlet. Forewings black, with grey veins. Hindwings scarlet with a black costal margin and apical spot being continued as a narrow marginal line to the long-haired proximal angle. Expanse of wings: 20 mm. Mexico; Guatemala; Costa Rica; Amazon.

L. thermeola *Dogn.* (33 f) has much longer and narrower wings than the preceding. Body blackish-brown with a green reflection; abdomen laterally striped red. Forewings purple-brown, in the basal halves with a leaden lustre, in the marginal halves with a golden lustre. Hindwing carmine, with a blackish-brown border and proximal margin. Expanse of wings: 20 mm. Colombia.

L. unifascia *Rothsch.* (33 f). Head blackish-brown with a silvery grey lustre; collar yellowish-red, thorax dark brown, abdomen above carmine, beneath with yellow and black bands. Forewings dark brown, scaled grey, with a yellow antemedian band not reaching the costal margin. Hindwings carmine with a narrow, blackish-brown border. Expanse of wings: 16 mm. Colombia.

L. endochrysis *Dogn.* (33 f) is a pretty, greatly deviating species. Head and thorax black, with a leaden-grey lustre; abdomen blackish-brown, laterally spotted orange. Forewings leaden grey with a black, wedge-shaped spot from the cell-end to the margin; the median and its branches likewise striped black. Hindwing blackish-brown, in the proximal half orange-yellow. Expanse of wings: 22 mm. Colombia.

L. pascuala *Schs.* (33 f) is lighter greyish-brown than the preceding, with a yellow palpal base, throat and collar, the abdomen being carmine with an orange anal tuft and the ventral side whitish towards the base. Forewings with a faint purple reflection. Hindwings carmine, towards the costal margin yellow, in the cell with a fine, small hyaline stripe, below it a thick, blackish-brown stripe. Margin black. Expanse of wings: 20 mm. Brazil (São Paulo).

L. olivacea *Schs.* (34 i). Head, thorax, and forewings silvery greyish-brown, collar and neck orange, abdomen carmine like the hindwings which are bordered with a brownish grey at the costal margin, with a blackish brown at the distal margin. Expanse of wings: 20 mm. São Paulo.

L. molybdiptera *Schs.* (33 f). Anterior body and forewings of a deep black, the latter on the veins striped blue with a leaden lustre, also the apical third being suffused in the same way. Abdomen and hindwings blackish-brown. Expanse of wings: 20 mm. Mexico (Jalapa).

L. nitens *Hmps.* (33 f) is distinguished from the other species by the golden green forewings and anterior body; the latter with a coppery reflection. Abdomen and hindwings blackish-brown with a bluish tint. Expanse of wings: 24 mm. Bolivia.

43. Genus: **Callisthenia** *Hmps.*

Very closely allied to the preceding genus; the palpi are somewhat shorter, the ♂ antennae with very long bristles and ciliae. On the forewing the upper median vein rises with the lower radial from the lower angle, on the hindwing the middle radial somewhat above the lower angle; all the rest as in *Lamprostola*. The species are similarly marked as *Prepiella*.

C. plicata *Btlr.* (34 k). The body is golden yellow, on the abdomen above carmine; the collar and ventral segments finely bordered with black. Forewings golden yellow, in the basal and marginal areas on the veins striped purple black, in the discal area 2 transverse lines and a red discal spot. Hindwings carmine with a small, black apical spot. The ♂ forewing exhibits above in the cell a very thickly scaled fold. Expanse of wings: 18 mm. From the Amazon (Espiritu Santo) and Peru.

C. costilobata *Rothsch.* (34 k) is well distinguished by the costal margin of the forewing being before the middle concavely excised and behind it sinuate in the shape of a lobe. The anterior body is light yellow, mixed with brown, the abdomen is above red-brown, beneath light yellow. Forewings light yellow, in the basal part and marginal area on the veins striped dark brown, leaving a yellow, red spotted transverse band free in the disc, which is bordered by dark brown lines, the distal one of which forms a pointed tooth outwards on the discal fold. Hindwings carmine, border and proximal margin dark brown. Beneath the fore- and hindwings exhibit scent-scale spots. Expanse of wings: 18 mm. Peru.

C. lacteata *Btlr.* (34 k) is distinguished by thickly strewn, yellowish scales on the hindwing of the ♂, on the upper surface of it behind and below the lower cell-angle with a deep excision. Anterior body blackish-

brown, abdomen carmine. Forewings yellowish-white with brown striped veins and purple brown spots in the middle of the proximal margin and at the proximal angle. Hindwings carmine-rosy with a faded dark apical spot. Expanse of wings: 18 mm. Amazon.

variegata. **C. variegata** Wkr. (34 k) differs from the preceding by long, yellowish scales at the end of the abdomen. Head yellow and pink, collar carmine-rosy; thorax yellowish-white, spotted dark. Abdomen above scarlet, beneath yellow, with black bands. Forewings marked very much like in *plicata*, but of a yellowish-white ground-colour, the discal area very narrow. Hindwing scarlet with a black apical spot. Expanse of wings: 18 mm. Amazon to Peru.

angusta. **C. angusta** Schs. (34 k) is the smallest species. Head dark grey; thorax black, ends of shoulder-covers red. Abdomen above red, beneath yellowish. Forewings black, in the basal and marginal area striped in an isabel-colour between the veins, with a broad, yellow postmedian band with a red discal spot in it. Hindwing orange with a black apex. Expanse of wings: 13 mm. French Guiana.

44. Genus: **Hypermaepha** Hmps.

Proboscis well developed; the porrect palpi project beyond the forehead; antennae ciliated, above thickened by scales. Wings rather short and broad. On the forewing the upper median vein rises shortly before the lower cell-angle, the two lower radial veins from it, the upper one from the angle; the two lowest subcostal veins are petioled, the third being absent; the uppermost anastomoses with the costal. On the hindwing the upper median vein is petioled with the lower radial vein; the middle radial is absent; the upper one anastomoses with the subcostal. Only 1 species is known.

sanguinea. **H. sanguinea** Btlr. (34 k) is brown on the head and thorax; the abdomen is above carmine with a black anal apex, beneath brown. Forewings brown; hindwings carmine with brown fringes and costal margin. Expanse of wings: 12 mm. Amazon, Rio Jutahi.

45. Genus: **Chrysochlorosia** Hmps.

From the preceding genus it differs by shorter palpi, shorter spurs on the tibiae, and longer, narrower wings with a round apex. On the forewing the veins are about the same, but the upper radial comes from below the upper cell-angle, and the 3rd subcostal vein is present. On the hindwing the cell is very long; the upper median anastomoses with the lower radial vein, the upper radial is petioled with the subcostal. 4 species distributed from Colombia across Ecuador as far as Bolivia.

splendida. **C. splendida** Drc. (34 i). Body greenish-golden with a coppery and metallic blue lustre; the black antennae are white at their ends. Forewings golden green, the margins of a deep blue, a similar short stripe at the subcostal base. Hindwings thinly scaled, bluish black, in the ♂ suffused with a metallic green. The under surface is metallic green. Expanse of wings: 36 mm. Ecuador and Bolivia.

superba. **C. superba** Drc. (34 i) greatly resembles the preceding, but it is somewhat smaller, the body of a pure metallic green, also the antennae which likewise have white tips; the last abdominal ring metallic blue. The abdomen is reddish beneath. The forewings are more orange golden with blue and green reflections, at the distal margin broadly bordered with black; fringes blue. Hindwings black. The under surface is greenish-black. Expanse of wings: 33 mm. Colombia.

magnifica. **C. magnifica** Schs. (34 i). Likewise allied to *splendida*, but much smaller. Body metallic bluish-green. Forewings dark green, distal margin black, at a certain exposure to light with a blue reflection. Hindwings black with green fringes. The under surface is dark bluish-green. Expanse of wings: 22 mm. Costa Rica.

callistia. **C. callistia** Hmps. (34 i). Head, collar, and shoulder-covers golden green, thorax black, on the mesothorax with a copper spot; abdomen golden green with coppery and metallic blue reflections. Forewings golden green, towards the base more coppery, margins, veins, and folds striped deep blue. Hindwings blackish-brown with a blue reflection, at the proximal margin golden green, at the distal margin blue. Expanse of wings: 30 mm. Bolivia.

46. Genus: **Odozana** Wkr.

It contains quite a number of small, partly very similar species. Proboscis well developed; the short palpi protrude forward; antennae of the ♂ with ciliary bristles. The abdomen mostly exhibits on the sides of the second ring very long hair-tufts, on the last ring shorter ones. On the long, narrow forewings the upper median vein rises below, the middle radial vein rather far above the lower cell-angle; the upper radial comes from below the upper angle; the uppermost subcostal vein anastomoses with the costal. On the hindwing the upper median and lower radial are coalescent; the middle radial is absent, the upper one is petioled with the subcostal.

floccosa. **O. floccosa** Wkr. (= *trichiura* Fldr.) (34 i) is in the ♂ distinguished by the long black hair on the outside of the posterior tibiae. The proximal margin is strongly convex, and at the proximal margin of the

hindwings a lobular appendage. Anterior body and forewings purple brown; ends of the shoulder-covers, abdomen, and the base and proximal margin of the hindwing carmine. The lateral hair-tufts on the abdomen orange, the venter is blackish. — In the form *reducta* form. nov. (= ab. 1 *Hmps.*) only the proximal margin of *reducta*. the hindwing is red; — in *ochreivitta* form. nov. (= ab. 2 *Hmps.*) (34 k) there is an ochreous-yellow, diffuse *ochreivitta*. spot in the cell-end of the forewing. Expanse of wings: 20 mm. From Brazil (Ega).

O. obscura Schs. (34 k) is without the hair on the posterior tibiae, the forewings and hindwings *obscura*. are of a normal shape. Anterior body and forewings black, suffused with a deep green, with a purple reflection; abdomen and hindwings black; the anal hairing in the ♂ is whitish. Expanse of wings: 18 mm. Brazil (Rio de Janeiro).

O. methaemata *Hmps.* (= *floeeosa* *Drc.* nec *Wkr.*) (34 k) looks almost exactly like *floccosa* *Wkr.*, *methaemata*. but the ♂ is without the tibial hairing, the wings being normal. The thorax is more extensively carmine, all the rest like there. Expanse of wings: 18 mm. Panama.

O. sixola Schs. (34 l) resembles the preceding. Head and collar black, thorax and abdomen above *sixola*. red, beneath black. Forewings blackish-brown, with fine iridescent stripes. Hindwing black, at the proximal margin carmine. Expanse of wings: 18 mm. Costa Rica.

O. roseiceps *Rothsch.* (34 l) is very similar. Forehead and palpi pink, the latter at the ends brown; *roseiceps*. vertex carmine, like the collar, shoulder-covers and abdomen; thorax and ventral side red-brown. Forewings red-brown; hindwings carmine with a red-brown marginal band. Expanse of wings: 20 mm. Peru.

O. patagiata *Dogn.* (34 l) is brown on the body with a metallic lustre; shoulder-covers and lateral *patagiata*. stripes at the base of the abdomen scarlet. Forewings golden brown, hindwings scarlet with a narrow, blackish-brown marginal band. Expanse of wings: 20 mm. Bolivia.

O. inconspicua Schs. (34 l) is dark brown on the head, collar, and wings; the forewings with fine iridescent *inconspicua*. stripes. Thorax and the hair-tufts at the base of the abdomen carmine. Abdomen otherwise black. Expanse of wings: 17 mm. Costa Rica.

O. decepta Schs. (34 l). Head and collar bluish-black. Thorax and forewings dark brown, with iridescent stripes. Abdomen above carmine, at the base brown, beneath black. Hindwings dull dark brown. Expanse of wings: 19 mm. Costa Rica.

O. unica Schs. (34 l). Head and thorax dark brownish-grey. Abdomen above red, beneath brownish-grey. Forewings brownish-grey, at the base and proximal margin darkened. Hindwings red, at the apex and distal margin brownish-grey. Expanse of wings: 17 mm. Mexico (Cordoba).

O. cocciniceps Jones (34 l). Head brilliant rosy, on the vertex spotted dark, collar anteriorly likewise *cocciniceps*. rosy, posteriorly black; thorax, abdomen and legs sooty black; so are the forewings. Hindwings rosy, bordered with black. Expanse of wings: 20 mm. Castro (Paraná).

O. margina Schs. (34 l), like the following species, has no hair-tufts at the base of the abdomen. Head *margina*. blackish-brown, behind the antennae striped carmine. Palpi orange. Thorax black. Collar and borders of the shoulder-covers striped carmine, chest and legs the same. Abdomen carmine. Forewings purple blackish, with a yellow inner-marginal stripe. Hindwings carmine, with a black marginal band. — In *lutescens* form. nov. *lutescens*. (= ab. 1 *Hmps.*) from Peru and Bolivia the stripes on the head, collar, borders of the shoulder-covers, and legs are yellow. The type flies in Brazil, Peru and Bolivia. Expanse of wings: 16 mm.

O. endoxantha Jones has a dull yellow body; terminal joints of the palpi, and forehead black. *endoxantha*. Forewing sooty brown, with a broad, yellow inner-marginal stripe, opposite at the cell-end a yellow costal-marginal spot. Hindwings yellow, bordered with black, at the apex more broadly so. Expanse of wings: 22 mm. Castro (Paraná).

O. leucota *Hmps.* (34 l) is quite differently coloured: white, on the body with a slight yellowish-red *leucota*. tint. The forewings exhibit at the proximal angle a scaled tooth, and are likewise for the greatest part tinted reddish-yellow. An antemedian, indistinct, dark line, on the veins distally angled; in the lower cell-angle there is a black dot; a postmedian, somewhat dentate, curved line with reddish-yellow spots behind it. Margin and fringes spotted dark. Hindwings brownish-grey with white fringes. Expanse of wings: 18 mm. Panama.

O. domina Schs. (34 l) is brownish-grey, on the head and thorax with a rosy collar. Palpi and legs *domina*. orange-yellow. Abdomen carmine, with an orange anal tuft. Forewings brownish-grey, hindwings darker, the latter at the proximal margin pink. Expanse of wings: 18 mm. Brazil.

47. Genus: **Ascaptesyle** Dyar.

Proboscis developed; the correct palpi project beyond the forehead. On the forewings the upper median vein rises before the lower cell-angle, the two lower radial veins are petioled, the upper one comes from below the upper cell-angle; the uppermost subcostal vein is strongly bent towards the costal, though it does not anastomose with it. On the hindwing the upper median anastomoses with the lower radial vein, the middle radial

comes with the lower one from the same place, the upper radial anastomosing with the subcostal vein. *submarginata*. **A. submarginata** Schs. (34 n) is greyish-brown on its head, thorax, and forewings, the abdomen is dark brown. Hindwings earmine, finely bordered with black, at the apex more broadly so. Expanse of wings: 20 mm. Trinidad.

48. Genus: **Leucorhodia** Hmps.

Very closely allied to the genus *Odozana* and distinguished only by the absence of the 3rd subcostal vein on the forewing, and by the upper median vein being petioled with the lower radial vein on the hindwing. Only one species:

ragua. **L. ragua** Drc. (= *maroniensis* Schs., *roseata* Roths.) (34 m). Head and thorax are yellowish-white, the latter tinted brown. Abdomen light pink. Forewings yellowish-white, the costal-marginal base blackish-brown; of the same colour is a stripe extending from the base along the median to the margin; at the cell-end there is a dark dot. Hindwings pink. Expanse of wings: 18 mm. Guatemala.

49. Genus: **Procridia** Hmps.

Very different by the structure, and course of the veins. Proboscis developed; the haired palpi are extremely short; the antennae are likewise short, in the middle thickened and covered with scales. At the posterior tibiae there are no middle spurs, the end-spurs being extremely short. The forewings are narrow, the costal margin in the middle convex; the median veins are petioled with the lower radial vein, the middle radial is absent; the upper radial is petioled with the 2 lowest subcostal veins, the 3rd and 4th are absent, the uppermost terminating separately into the costal margin. On the hindwings the upper median vein anastomoses with the lower radial vein, the middle one being absent, the upper one being petioled with the subcostal.

metallica. **P. metallica** Dogn. (34 n) is golden green on the head and thorax, intermixed with coppery scales, the abdomen is more bluish-green. Forewings golden green, at the margins more blue; in the marginal area there is a large, orange spot. Hindwings blackish-brown with a blue reflection, with an indistinct, yellow marginal band, being narrowed towards the anal angle. Expanse of wings: 24 mm. Ecuador.

50. Genus: **Phanlosia** Hmps.

Proboscis developed; the slender palpi are ascending, rather short; abdomen with a large anal tuft. On the forewing the two lower radial veins rise from the cell-angle, the upper one being petioled with the 3 lowest subcostal veins, the two uppermost ones being separated. Hindwings like in the preceding genus.

sordida. **P. sordida** Btlr. (34 v). Head and thorax whitish, with a brown hue. Abdomen grey. Forewings white, strewn and clouded reddish-brown; in the lower cell-angle there is a dark dot; the apex is of a purer white with a black spot in it. Hindwings light brownish-grey. Expanse of wings: 14 mm. Amazon.

51. Genus: **Xantholopha** Hmps.

Proboscis well developed; the obliquely ascending palpi do not reach the vertex; antennae of the ♂ doubly combed. On the forewing the upper median and lower radial vein rise in common from the lower cell-angle, the middle radial close above it, the upper one from below the upper angle. The uppermost subcostal vein approaches the costal and is strongly curved. On the hindwing the two lower radial veins are on a long pedicle with the upper median vein, the same being the case with the upper radial and the subcostal vein.

purpurascens. **X. purpurascens** Schs. (34 n) is purple-blackish on its head, thorax, and forewings. Collar, palpal base, and throat are orange. Abdomen and hindwings black, the clasping-organs of the ♂ orange. Expanse of wings: 28 mm. Brazil.

52. Genus: **Neothyone** Hmps.

It differs from *Thyone* by somewhat longer, more slender palpi, shorter and broader wings with a rounded apex. On the forewing the upper median and the lower radial vein are petioled, the upper radial is on a common pedicle with the 3 lower subcostal veins.

xanthaema. **N. xanthaema** Dogn. (34 n). Body reddish-yellow, on the ventral side whitish. Forewings yellow, suffused with red, particularly in the discal area in which there is a brown spot in the shape of an inverted U. An antemarginal, indistinct, red line. Hindwings yellow, at the apex dusted red. Expanse of wings: 16 mm. French Guiana.

53. Genus: **Thyone** Wkr.

Proboscis and palpi very much stunted; ♂ antennae ciliated. Spurs of the tibiae short, on the posterior tibiae the middle spurs are absent. Abdomen roughly haired. The long, narrow forewings show exactly the same venation as the preceding genus, except the uppermost radial rising from below the upper cell-angle. On the hindwing the upper median and lower radial vein are petioled; the middle radial comes almost from the middle of the transverse vein, the upper one being petioled with the subcostal.

T. celenna Schs. (34 n). Body purple black, on the thorax spotted white and with a metallic green *celenna*. head and collar. Forewings white with veins striped purple black, and black spots at the costal margin, behind the cell and in the middle of the margin. Hindwings brownish black. Expanse of wings: 30 mm. Brazil.

T. dremma Dyar (34 n). Head yellow, thorax orange brown. Abdomen light yellow. Forewings *dremma*. orange-yellow, with a yellow median band, bordered with a purple brown on both sides; before and behind it the veins are striped carmine. Hindwings yellow-brownish. Expanse of wings: 17 mm. British Guiana.

T. purpurea Jones (34 n) is on the anterior body deep purple brown, with a metallic blue lustre; *purpurea*. on the metathorax there is a yellowish-white spot; abdomen dark brown, posteriorly lustrous blue. Forewings purple-brown, at the base and costal margin suffused with a metallic blue; before the middle there are below and above the inner-marginal vein oblique, oblong spots of yellowish-white; a similar one near the cell-end, and one above it; behind the middle a macular band. Hindwings dark brown. Expanse of wings: 36 mm. Brazil.

T. trimaculata Jones (34 n). Entirely white, on the forewings with a small black spot on the inner- *trimacu-* marginal vein at the end of the basal third and a second spot near the proximal angle; a 3rd spot is situate *lata*. behind the cell on the middle radial, and one or two very small ones about the middle of the subcostal. Expanse of wings: 25 mm. Castro (Paraná).

T. placida Schs. (34 b) is similarly marked as *celenna*, but of a greyish-brown ground-colour, and *placida*. much smaller expanse of wings (only 24 mm). Brazil (São Paulo, Castro [Paraná]).

T. parima Schs. (35 a) is light brown, on the body somewhat mixed with grey, with faded grey *parima*. spots on the forewing in the cell-spaces in the basal half, in the cell-end, and before the margin. Hindwings light brown. Expanse of wings: 28 mm. Brazil (São Paulo).

T. perbella Schs. (34 n) is very differently coloured. Head yellow, collar and thorax orange, abdomen *perbella*. more ochreous-yellow. The forewings are yellow at the base, and this colour passes from orange and red into brown as far as the discal area; then follows a broad, pale yellow median band, behind which the ground-colour is again brown, fading away into an ochreous yellow towards the margin; veins in the marginal area dark brown, at the base of the costal margin a small black spot. Hindwings pink-yellowish. Expanse of wings: 16 mm. French Guiana.

T. muricolor Schs. (35 a) is unicolorously leaden grey, on the forewing with a slight violet reflection. *muricolor*. Abdomen more greyish-black, like the hindwings. Expanse of wings: 18 mm. Cayenne. — A somewhat darker ♂ which, however, certainly belongs to the same species, is before me from Caparo (Trinidad), belonging to the German Entomological Museum.

T. grisescens Schs. (35 a) is very closely allied to *muricolor*, but somewhat larger, on the body and *grisescens*. wings violettish-grey, abdomen and hindwings somewhat darker. Expanse of wings: 22 mm. Costa Rica.

T. tincta Hmps. (35 a) is white, on the forehead, legs and abdomen tinted brownish-grey, antennae *tincta*. curled black. Forewing at the base of the costal margin black; inner-marginal area and under surface blackish-brown. Expanse of wings: 26 mm. Bolivia.

T. melanocera Schs. (35 a) is purely white, with quite black antennae, also the anterior legs and the *melanocera*. extreme ends of the middle and posterior tarsi are black. Expanse of wings: 22 mm. Trinidad, Venezuela, Surinam.

T. simplex Wkr. (= *alba* Drc., *parvita* Schs.) (35 a) is entirely of a pure white. Expanse of wings: *simplex*. 18 to 22 mm. From Mexico to Brazil.

54. Genus: **Afrida** Mschlr.

A doubtful genus. MOESCHLER, who founded the genus, placed it to the *Lithosiidae*, HAMPSON to the *Nolinae*; quite recently DYAR has placed it to the *Noctuidae*, since the costal vein of the hindwing, contrary to HAMPSON's assumption, does in fact not rise from the middle of the cell, but anastomoses with it only for a short distance. If we deal with the genus here, it is only not to introduce an innovation for the present. — Proboscis developed; the porrect palpi extend beyond the forehead; tibiae with long spurs. Venation of the forewings similar as in the preceding genus, but the 3rd subcostal vein is absent and the uppermost does not anastomose with the costal. Veins of the hindwings likewise the same as in the preceding except the course of the costal. Whereas HAMPSON's Catalogue mentioned only 4 species, DYAR who studied the genus very closely, increased the number to more than 2 dozen species which, however, are difficult to separate.

A. tortriciformis Mschlr. is greyish-white, beneath more blackish. Forewing with a dentate ante- *tortricifor-* median line, not reaching the proximal margin, with a black subcostal dot on its proximal side. An antemedian, *mis*.

blackish-grey band is bordered by undulate black lines; at the cell-end a black spot; marginal area clouded blackish-grey with a black, marginal row of dots, hindwings tinged brownish-grey; the anal angle somewhat produced and thickly covered with black scales; fringes black. Expanse of wings: 12 mm. Jamaica.

tortricifac-
cics. **A. tortricifacies** Dyar (35 b) is very similar, dusted more greyish-green, with purple black markings; opposite the black cell-spot, at the proximal margin, there is a triangular one with a tooth inwards on the inner-marginal vein; before the purple blackish marginal dusting in the middle a small, round, red spot. Hindwings whitish, with a blackish-brown marginal band and discal spot. The anal angle is scaled white. Expanse of wings: 11 to 13 mm. San Domingo.

mesomela-
na. **A. mesomelaena** Hmps. (35 a) from Jamaica is considerably larger and distinguished by a complete blackish-brown median band, being bordered by black lines and strangulated in the cell and on the submedian fold, whilst at the proximal margin it is much broader. Expanse of wings: 22 mm.

basipuncta-
ta. **A. basipunctata** Rothschild. (35 a) shows the broadest median band, the whole median area being suffused with a coppery brown. In the basal area there are small black spots at the costal margin and on the submedian fold; the marginal area bordered by a curved black line is also brown; before the apex there is an oblique black spot, on the discal fold another one. Hindwing silvery white with a brownish marginal line. Expanse of wings: 24 mm. Peru.

flavifera. **A. flavifera** Dogn. (35 a) is very similarly coloured and marked; the black line bordering on the brown median area towards the base, makes a strong bend towards the base at the proximal margin; behind the upper cell-angle there is yellow colouring interspersed. The white hindwings show a brown discal spot and antemarginal shades. Expanse of wings: 22 mm. Colombia.

viridifera. **A. viridifera** Hmps. (= *melicerta* Hmps. part.) (35 a) is marked by a yellowish-green spot in the basal part before the curved, black, additional basal line, another spot like it is situated above the cell-end; there is yellowish-green dusting also behind the middle below the costal margin. The marginal area is extensively purple brown, proximally bordered with black. Expanse of wings: 20 mm. Bolivia.

parvula. **A. parvula** Schs. Head and thorax violet-reddish, abdomen more brownish. Forewings reddish-grey, intermixed with an olive-ochreous colour, with a broad, curved, black antemedian shade not reaching the proximal margin; the other markings like in the preceding, but rather blurred; the dusting of the marginal area lighter brownish with a purple brown spot in the middle before it; hindwings brownish-grey, towards the margin darker, with a dark discal spot. Expanse of wings: 14 mm. Costa Rica.

basiposis. **A. basiposis** Dyar (35 b) is much smaller than the preceding, otherwise very similarly marked; it is distinguishable by almost entirely white hindwings; on the forewing, near the base, a broad, obliquely quadrangular, black spot. Expanse of wings: 10 mm. San Domingo.

interdicta. **A. interdicta** Dyar (35 b) is most easily distinguishable from the two preceding species by the red, not blackish, spot before the middle of the margin of the forewing. They are dirty white, densely dusted olive; markings otherwise similar; the discal band is dissolved into diffuse dark dusting, the border-lines indistinct, the most distinct at the costal margin; behind there are 3 costal-marginal spots. Hindwings whitish, with a dark discal spot and marginal dusting. Expanse of wings: 10 mm. Cuba (Baracoa).

minuta. **A. minuta** Drc. (35 b) is distinguishable from the preceding by only scanty olive dusting from which the transverse bands are distinctly prominent, not so hazy. A somewhat larger species with the hindwings dusted brownish-grey. Expanse of wings: 18 mm. Texas, Mexico, Costa Rica.

charientis-
ma. **A. charientisma** Dyar (35 b) greatly resembles *minuta*, being smaller, with almost white hindwings. Forewings white, only faintly tinged olive; a purple brown dentate basal spot, the base itself light; the broad, brown discal band is bordered by black lines, dentate, on the submedian strangulated. Expanse of wings: 10 mm. Cuba.

pnixis. **A. pnixis** Dyar (35 b) is without any olive on the forewing; the discal band grows much broader towards the apex and is not in the middle, like in the other species, crossed by an oblique line. Panama.

phasma. **A. phasma** Dyar (35 b). In this species and the following the dark shading of the marginal area is absent. The forewing is pointed, the discal band partly dusted dark. The white ground-colour is faintly yellowish. Hindwings whitish, unspotted. Expanse of wings: 15 mm. Brazil (Castro Parana).

sceletozona. **A. sceletozona** Schs. (35 b) resembles *phasma*, the forewings being more broadly quadrangular, not so pointed; the discal band is only denoted by the dark border-lines, without any dark dusting in the middle, Costa Rica.

gymnes. **A. gymnes** Dyar (35 b) is very well distinguished by the discal band being broadly interrupted in the middle, by which the small animal assumes a characteristic exterior.

cosmiogramma. **A. cosmiogramma** Dyar (35 b). Forewings white, in the basal area brownish, bordered by a dark demi-line; the discal band is broad, filled up with brown and bordered by straight black lines; the proximal

one on the submedian somewhat angular, the distal one on the middle radial; the proximal half is darker brown than the distal half; in the marginal area a dark, hazy shade touching the discal band in the middle. Hindwing whitish, with a grey discal spot and marginal band. Expanse of wings: 10 mm. Cuba.

A. ydatodes Dyar (35 b) is very much like the preceding, but with much hazier markings; the white *ydalodes*. ground-colour is dusted grey, the border-lines of the discal band more indistinct. Expanse of wings: 10 mm. Florida.

A. ciliata Hmps. is very much like *sceletozona*, the body entirely white, forewings tinged light orange-*ciliata*. yellow; the marking is otherwise the same. Hindwings white with traces of undulate, discal and postdiscal lines; at the margin and beneath darkened by black scales. Expanse of wings: 18 mm. Costa Rica.

A. melicerta Drc. (35 b) is the largest species of the genus and very distinctly marked. Forewing *melicerta*. silvery white, without a discal band, but instead of it in the middle of the costal margin a large, triangular spot with a round, lower point; at the distal margin a dark brown spot. Palpi, forehead and antennae black, under surface and abdomen blackish. Hindwings white with an indistinct discal spot and a slightly darkened apex, in the ♀ dusted darker. Expanse of wings: 24 mm. Costa Rica.

A. coagulata Dyar (35 c) is somewhat smaller than the preceding, the costal-marginal spot more *coagulata*. four-cornered, below not round; the black markings on the forewing very narrow, fine and dentate. Expanse of wings: 18 to 20 mm. Mexico.

A. amphithrepta Dyar (35 c) and the following are distinguished by much scantier markings. Forewings *amphithrepta*. silvery white; two thirds of the costal margin are occupied by a broad, purple-blackish shade crossed behind the base by a white streak, and bordered with black. Before the apex at the costal margin a black curved streak; at the distal margin a shade projecting in the middle as far as below the cell; above and below it one black dot each; base somewhat yellowish; an antemedian line, curved like a sling, runs from the proximal margin to the cell. Hindwing whitish, with a grey margin and discal spot. Expanse of wings: 15 mm. Province of Salta (Argentina).

A. melampages Dyar (35 c) differs from the preceding by a much larger, more distinct, four-cornered *melampages*. costal spot touching the marginal spot. Hindwings more smoky-grey. Expanse of wings: 16 mm. Brazil: São Paulo.

A. melenita Dogn. (35 c). Forewings white, with brown markings. In the first quarter of the costal *melenita*. margin there is a dot; in the middle a broad, square spot rounded below and before the apex a small moon-spot; the other marking similar as in the others. Hindwing white, at the margin blackish. Expanse of wings: 11 mm. French Guiana.

A. zoëphila Dyar (35 c) is very much like the preceding, larger, with angularly broken lines in *zoëphila*. the basal area, those of the preceding being absent. Expanse of wings: 16 mm. Mexico.

A. oligoglotta Dyar (35 c) is characterized by a semicircular yellowish costal-marginal spot bordered *oligoglotta*. dark, below it the basal area is white; there are no subbasal linear markings, only at the base of the costal margin there is a purple-brown triangular spot; the other markings similar as in the preceding; the marginal spot covers the whole proximal angle and extends proximally as far as the cell-end; in the middle of the proximal margin a black sagittiform spot. Expanse of wings: 14 to 15 mm. Brazil: Castro (Paraná).

A. polyglotta Schaus (35 c) differs from the preceding by the yellow colouring of the basal area below *polyglotta*. the costal spot in which there is a subbasal linear marking; the distal line, at its subcostal distal curve above the angle of the brown spot, forms a spot; markings well developed. Costa Rica.

A. superciliosa Dyar (= *melicerta* ab. 1 Hmps.) differs from the preceding by less developed markings; *superciliosa*. the subcostal spot is absent; at the proximal margin of the purple marginal spot there runs a narrow black line forming an incomplete eyespot-marking towards the apex; in the basal third of the proximal margin there is a dentate line forming a sling which encloses an orange spot at the base. Expanse of wings: 15 mm. São Paulo.

A. claricosta Dyar (35 c). In this species and the following the middle costal spot is entirely absent. *claricosta*. Forewings silvery white; at the costal margin 3 minute black spots and an arcuate streak before the apex. Marginal area like in the preceding; basal area unmarked. Hindwing dusted grey, margin and discal spot darker. Expanse of wings: 10 to 12 mm. French Guiana.

A. zolda Dyar (35 c) is very much like the preceding, but in the basal area of the forewing there *zolda*. is a doubly broken, blurred linear marking. Expanse of wings: 16 mm. Mexico.

55. Genus: **Euzeugapteryx** Dyar.

Proboscis stunted; palpi short and slender; male antennae ciliated. On the forewing the upper median and the two lower radial veins are all separated, the upper radial vein from below the upper cell-angle; the two lower ones as well as the two upper subcostal veins are on pedicles, the 3rd is absent. The ♂ shows beneath

a costal-marginal fold covered with hair, and near the base below the cell a prominent scent-spot. Cell of the hindwing very short; the lower radial vein anastomoses with the upper median vein; the middle one is absent, the upper one anastomoses with the subcostal; on both sides of the costal-marginal vein thick, rough scales. The margin of the hindwing is broadly excised below the apex. Only 1 species:

speciosa. **E. speciosa** Schs. (35 g). Body blackish-brown, with a yellow anal tuft, venter grey. Forewings light brown, thickly dusted blackish-brown, below the costal margin the darkest. Hindwings blackish-brown, in the costal-marginal area lighter, apex black. The scent-scales of the under surface are ochreous-yellow. Expanse of wings: 16 mm. French Guiana.

56. Genus: **Josiodes** Fldr.

One of the more numerous genera, containing mostly bright orange species marked with black, often exhibiting similarities with Aretiids and Geometrids. Proboscis developed; the short palpi are porrect; antennae of the ♂ provided with bristles and cilia. Posterior tarsi with moderately long spurs. On the mostly long and rather narrow forewing the upper median vein rises before the cell-angle, the middle radial vein above it, the upper one below the upper angle; the two upper subcostal veins come from the cell and terminate into the costal margin, the 3 lower ones on a common pedicle. Cell of the hindwing long, the upper median vein likewise rising before the cell-angle; the two lower radial veins rise from it, the upper one is petioled with the subcostal vein. The species fly in day-time and at night.

myrrha. **J. myrrha** Cr. (= *fulvia* Clerck) (35 d) is of a bright orange on its body and wings; palpi, forehead, antennae, legs, and a dorsal stripe on the abdomen bluish-black. On the forewing the costal margin and distal margin, as well as a subapical oblique band are black, like on the hindwing the distal margin which is somewhat narrowed near the median veins. Expanse of wings: 34 mm. Surinam.

suapurensis. **J. suapurensis** Roths. (35 d) resembles *myrrha*, the black colour on the wings much more extensive, the black marginal band of the hindwing projects to the cell and below the submedian fold inwards, at the latter almost to the base. The abdomen is almost entirely black, only at the base laterally somewhat orange. In the much larger ♀ the black colour is more reduced, particularly on the hindwing. Expanse of wings: ♂ 32 mm, ♀ 38 mm. Venezuela.

intensa. **J. intensa** Roths. (35 e), described according to a ♀, greatly resembles the ♀ of the preceding, though it is larger, the border of the wings more uniform. Expanse of wings: 40 mm. Surinam.

nigrobasalis. **J. nigrobasalis** Roths. (35 e). Head and thorax quite black, also the abdomen, which exhibits some orange only on the sides. Forewing at the base black, only the cell remains orange as far as the base. Hindwing in the ♀ quite black, only the proximal margin and a small spot behind the cell orange. The ♂ has orange hindwings with a black border, less black at the base of the forewing, and the orange oblique band in the apex is absent altogether. Expanse of wings: ♂ 34 mm, ♀ 46 mm. British Guiana.

indecisa. **J. indecisa** Btlr. (35 d) is similar to the preceding, but the costal margin of the forewing is only in the basal third subcostally black, the proximal margin is broader black, and in the submedian space there is in the middle above it another black stripe. Hindwings very broadly margined with black. The body is entirely black, only on the collar spotted orange, and on the abdomen with narrow lateral stripes. In *deccisa* form. nov. the proximal margin is much narrower black and the stripe above it is absent. Expanse of wings: 40 mm. Amazon.

toxaridia. **J. toxaridia** Drc. (35 d) likewise resembles the two preceding species, differing, however, by the body being all black with only orange-yellow shoulder-covers and abdominal stripes. Expanse of wings: 36 mm. Ecuador.

repleta. **J. repleta** Wkr. (= *abscissa* Hbn. p.p.) (35 d) is black on its head, thorax and abdomen, anteriorly with a blue reflection; sides and venter are orange except the 2 last rings. Forewings orange, costal and proximal margins black, like the apex and a subapical spot. Hindwings orange with a black costal margin and distal margin, with an irregularly dentate, proximal border not reaching the proximal angle. The ♀ exhibits a broader, subapical oblique band. — In *striata* form. nov. (= ab. 1 Hmps.) there occur black stripes on the hindwing in and below the cell, being confluent towards the base. The shoulder-covers sometimes exhibit small orange spots, the venter is occasionally quite black or banded black. Expanse of wings: ♂ 36 mm, ♀ 44 mm. Amazon.

immutata. **J. immutata** Wkr. (36 d) is most easily discernible from the preceding by a large, triangular, black inner-marginal spot of the hindwing, the distal margin being expanded. The body is bluish-black, on the shoulder-covers and sides of abdomen orange. Expanse of wings: 40 mm. Brazil.

fallax. **J. fallax** Btlr. (35 d) closely resembles *immutata* from which it differs by its broad black proximal margin and proximal angle, the subapical band being uniformly curved; on the hindwing the black is still broader. In the ♀ the orange lateral stripes on the abdomen broader. Expanse of wings: ♂ 36 mm, ♀ 42 mm. Brazil.

tenuifascia. **J. tenuifascia** Hmps. (35 e) is smaller, the orange colour on the forewing confined to a narrow median stripe, the subapical spot small and irregular. Expanse of wings: 30 to 32 mm. Brazil.

peruviana. **J. peruviana** Schs. Body like in the preceding. On the forewing the narrow, orange longitudinal band extends from the base to the transverse vein, then it bends round along the lower median vein almost as far as the border; the subapical spot is curved, almost transverse. On the hindwing a narrow, orange band below

the median almost extends to the margin, near which it is expanded. Expanse of wings: 40 mm. Peru.

J. semicirculata *Hmps.* (35 f) greatly resembles *peruviana*, but the subapical band is almost longitudinal and more or less parallel to the median band; besides there is a transverse streak on the forehead, the distal half of the collar and the shoulder-covers being orange. In the ♀ there appears besides an orange, ante-marginal band extending to the proximal angle. Expanse of wings: 30 mm. Ecuador, Bolivia. *semicirculata*.

J. mutans *Wkr.* (35 f) is sufficiently characterized by the absence of the subapical band; the orange basal part is broad, upwards somewhat concave owing to the rounded black costal margin. On the hindwing the proximal margin and a discal longitudinal stripe are orange. — **maculata** *form. nov.* (= ab. 1 *Hmps.*) is *maculata*, spotted orange on the collar and mesothorax. Expanse of wings: 36 mm. Amazon. *mutans*.

J. abscissa *Hbn.* (= *fixa* *Wkr.*, *inconstans* *Btlr.*) (35 d). Forewing similar like in the preceding, but besides with a subapical spot, the black with a blue reflection. The hindwing of the ♂ exhibits above below the cell-end a small orange spot being expanded beneath into a large orange spot; in the ♀ the hindwings are above quite black. Proximal margin in the ♂ orange, in the ♀ black. Expanse of wings: 34 mm. Amazon. *abscissa*.

J. clavata *Wkr.* (35 e). Forewings with a decidedly club-shaped orange spot like in *mutans*, and only traces of a subapical spot. The hindwing exhibits only beneath a faint, orange stripe at the lower cell-end. Expanse of wings: 34 mm. Amazon. *clavata*.

J. variana *Btlr.* (35 e) resembles *immutata*, but it is at once discernible by the black basal part of the forewing. The shoulder-covers are black, the orange lateral stripes very broad. Expanse of wings: 38 mm. Amazon. — **suffusa** *form. nov.* has black dusting in the disc of the hindwing and beneath quite orange abdomen. *suffusa*.

J. sexmaculata *Btlr.* (35 f). On the forewing like the preceding species, but the hindwing exhibits only an elliptic orange spot at the cell-end, being larger beneath. Expanse of wings: 40 mm. Amazon. *sexmaculata*.

J. mutata *Wkr.* (35 f). Forewings somewhat similar to *clavata*, but the base and basal inner-marginal half broadly black. Hindwings above quite black, beneath with a small orange spot. Expanse of wings: 38 mm. Amazon. *mutata*.

J. generans *Wkr.* (35 f). The orange spot of the forewing is reduced to an oblique spot in the middle, subapical spot small; hindwings quite black. — In **obscura** *Btlr.* the oblique spot is strongly narrowed and does not reach the subcostal above. Expanse of wings: 32 mm. Amazon. *generans*.

J. erythromelas *Wkr.* (35 e) exhibits on the forewing only the triangular postmedian spot reaching downwards only to the submedian fold; there are above only faint traces of a subapical spot, beneath it is more distinct. Hindwing beneath with a small orange spot in the cell-end. Expanse of wings: 36 mm. Amazon. *erythromelas*.

J. caerulescens *Hmps.* (35 e) is distinguished by an intense blue lustre; the oblique spot of the forewing is light yellow and removed more towards the margin. Expanse of wings: ♂ 38 mm, ♀ 46 mm. Colombia. *caerulescens*.

J. batesi *Fldr.* (= *entella* *Drc.*, *quadrifascia* *Rothsch.*) (35 f). From the preceding it differs by a broader orange stripe-band extending to the costal margin, and a small subapical spot. Hindwing beneath with an orange spot; abdomen laterally striped orange. Expanse of wings: 40 mm. British Guiana; Brazil. *batesi*.

J. celena *Wkr.* (= *trajecta* *Wkr.*) (35 f) greatly resembles *batesi*, but it has no subapical spot. Hindwings above and beneath quite black. In the ♀ the orange-yellow abdominal stripes only extend to the 5th segment, in the ♂ to the terminal segment. — **purpurata** *Btlr.* exhibits on the hindwing beneath a small orange spot. Expanse of wings: ♂ 30 to 34 mm, ♀ 40 mm. Distributed from Surinam, Brazil as far as Bolivia and Peru. *celena*.

140. Genus: **Marsypophora** *Hmps.*

Proboscis developed, palpi drooping and long haired; male antennae in the basal halves doubly combed, towards the tips ciliated. Posterior tibiae without any middle spurs. On the broad forewings all the subcostal veins are on a common footstalk; beneath the ♂ exhibits a small scent-scale spot above the inner-marginal vein of the forewing. The ♂ hindwing is small, exhibiting above in the cell a hairy spot and below the median a hairy fold, beneath in the cell-end a swelling; the lower radial vein is absent.

M. erycinoides *Fldr.* (35 g) is blackish-brown on its body and wings, on the venter white. The forewing exhibits in the proximal area a large, elliptic, orange spot. Hindwings light yellowish, at the border and submedianly blackish-brown. Expanse of wings: 24 mm. Colombia. *erycinoides*.

dissimilipennis. **M. dissimilipennis** Dogn. (35 g) extremely resembles the preceding. The orange colouring of the forewing is more extensive; the hindwings are black, in the costal-marginal half whitish, the hair in and below the cell yellow. Expanse of wings: 26 mm. Ecuador.

58. Genus: **Ptychoglene** Fldr.

Distinguished from the preceding genus by longer palpi, which are likewise porrect, projecting beyond the forehead and being densely scaled. Antennae rather short and stout; posterior tarsi with shorter spurs. On the forewing the venation is the same, only the uppermost subcostal vein anastomoses with the costal; the 5th subcostal vein rises nearer to the margin than the third. On the hindwing the upper median and lower radial vein are petioled, the middle radial being absent, the upper one rising with the subcostal vein from the cell-angle or on a short footstalk. A small number of species coloured red and black, most strikingly resembling certain *Syntomidae* (t. 9 a) and *Zygaenidae* (t. 26 c), so that they are partly only discernible by the venation.

pertunda. **P. pertunda** Dr. (35 g). Body black with a red collar. Forewings scarlet with a black marginal area; the red colour extends at the costal margin as far as near the apex, from where it runs obliquely proximal to the upper radial and from there vertically to the proximal margin. Hindwing black, with a narrow, red stripe at the base of the costal margin. Expanse of wings: 30 mm. Mexico.

xylophila. **P. xylophila** Drc. (35 g) is the same, but the red colour runs from the apex of the forewing in an oblique line to the base of the proximal margin; the border between red and black is irregularly dentate. Expanse of wings: 24 to 28 mm. From Mexico, Guatemala, and Nicaragua.

sanguineola. **P. sanguineola** Bsd. (35 g). A well known species with scarlet forewings distally bordered with black; the hindwings are of a lighter red. Collar black like in the following species. Expanse of wings: 30 mm. Mexico and Guatemala.

aequalis. **P. aequalis** Wkr. (= *haematodes* Dyar) (35 g) is like the preceding, but the hindwings are black with a red costal-marginal spot. Expanse of wings: 30 mm. Guatemala.

phrada. **P. phrada** Drc. (= *flammans* Dyar) (35 g) resembles *aequalis*, but the red of the forewing extends to the proximal margin; the hindwing exhibits beside the large red costal-marginal spot a red submedian stripe. In the ♀ the black border is broader. Expanse of wings: 30 mm. Distributed from Arizona to Mexico.

erythrophora. **P. erythrophora** Fldr. (35 h) is also like the preceding, but the proximal margin is much more broadly black; the red costal-marginal spot of the hindwing very narrow and small. Expanse of wings: 28 to 30 mm. Mexico.

coccinea. **P. coccinea** H. Edw. Head and thorax carmine, abdomen black, at the base red; antennae and palpal ends black. Forewing in the basal two thirds carmine, distally bluish-black with a dentate proximal border. Hindwing in the basal half red, distally black, likewise with a dentate border. Expanse of wings: 24 mm. Arizona.

stenodora. **P. stenodora** Dyar (35 h) is bluish-black on its body and wings, with a carmine longitudinal stripe on the forewing and hindwing. Expanse of wings: 28 mm. Mexico (Tehuacan, Puebla).

tenuimargo. **P. tenuimargo** Holl. (35 h). We reproduce here the figure of a butterfly from HOLLAND's „Moths-Book“, being distinguished from the other *Ptychoglene* by the narrowly margined forewings; described from Arizona; besides in Mexico. The figure with HOLLAND is most singularly labelled as „*Lycomorpha fulgens* Edw.“ which we have figured on t. 26 c and with which the species has probably been mixed up.

59. Genus: **Tuina** Btlr.

Separated from the preceding by the antennae being roughly scaled. On the forewings the uppermost subcostal vein does not anastomose with the costal; on the hindwing the pedicle of the upper median and lower radial vein is longer than in *Ptychoglene*.

cingulata. **T. cingulata** Wkr. (35 h) is deeply black on its body and wings; palpal base, shoulders, shoulder-covers, and base of forewings flesh-coloured. Expanse of wings: 38 mm. Mexico, Honduras, and Guatemala.

60. Genus: **Meterythrosia** Hmps.

Very much like the preceding, but with longer, porrect palpi. Veins of the forewings exactly like there. On the hindwing the upper median and lower radial vein is unpetioled, so is the upper radial and subcostal vein, both coming from the corresponding cell-angles. In the cell-end there is an elliptic scent-spot.

M. sangala Drc. (35 h). Body black; collar, shoulders, and a lateral spot on the 4 first abdominal rings orange, such is a short stripe at the base of the forewing. Hindwing carmine with a black marginal band. Expanse of wings: 34 mm. Guatemala.

61. Genus: **Cisthene** Wkr.

Proboscis well developed; palpi short, protruding forward. The comparatively short antennae are provided with bristles and cilia in the ♂, while in the ♀ they are thickened by rough scales. Posterior tarsi with moderately long spurs. The wings are comparatively broad. In the veins there is very little difference with *Josiodes*, on the forewing they are quite the same, on the hindwing the middle radial rises above the lower cell-angle — not together with the lower radial — and the costal vein rises much nearer to the base. The genus likewise contains quite a number of yellow and black insects which are mostly similar to each other. The ♀♀ are often considerably larger than the ♂♂.

C. lunaris Wkr. (35 i) is a small insect of pale colours, recognizable by the orange-yellow, longitudinal, diffuse spot in the base of the cell. The forewings are otherwise yellowish-grey with an orange-yellow median and marginal band and proximal margin. Hindwings orange, with a brownish-grey marginal band. Expanse of wings: ♂ 24 mm, ♀ 28 mm. Colombia.

C. prusias Drc. (35 i) is orange on its body like the preceding. Forewings black, with a very broad orange band occupying the whole middle of the wing, and a similarly coloured antemarginal band. Hindwing orange, in the distal third black. Expanse of wings: 30 mm. Mexico.

C. menea Drury (= *laetifera* Wkr., *latifasciatus* Btlr., *arctifascia* Btlr., *arida* Skinner, major *Rothsch.*) (35 i) is a very variable species differing from *prusias* almost only by the much narrower orange median band varying very much in its shape. The ground-colour is sometimes of a deep black colour, sometimes more greyish-black. The black margin of the hindwing likewise varies very much in its width. Expanse of wings: ♂ 28 to 34 mm, ♀ 40 to 52 mm. Distributed from Mexico to Colombia and Brazil, and very common. — The larva is light yellow with 4 or 5 very irregular, partly confluent, carmine transverse bands on each ring and very long yellow hair.

C. cynossema Drc. (35 i) is very much like *menea*, easily discernible by a large black spot in the basal part of the hindwing, reaching the proximal margin. Expanse of wings: ♂ 34 mm, ♀ 38 mm. Mexico and Guatemala.

C. quadrifasciata Wkr. (35 i) is smaller than the preceding, more blackish-brown in its ground-colour, and distinguished by quite blackish-brown hindwings with an orange spot from the middle of the costal margin to the median. Expanse of wings: 30 mm. Mexico.

C. praxis Drc. (35 k). This species initiates the series of species having the abdomen black above. The forewing is similarly marked as in the preceding species, the discal band is narrow, of an orange-yellow, on the median somewhat angled. Hindwing in the basal half orange-yellow, distally black. Expanse of wings: 28 to 34 mm. Mexico.

C. cypris Drc. (35 i) differs from *praxis* by its broader median band, the colour is a deeper orange. The black abdomen is orange towards the base and at the anal tuft. Expanse of wings: 30 to 38 mm. Mexico, Guatemala.

C. uncinata Hmps. (35 k) is distinguished by the entire absence of the orange median band on the upper surface; beneath there are traces of it noticeable. Hindwings quite blackish-brown. Expanse of wings: 36 mm. Colombia.

C. ruficollis Hbn. (35 k) exhibits a broad median band; the antemarginal band is divided into 2 spots: a triangular spot below the apex, a smaller one between the median veins. Hindwings dull black with a broad, orange median band. Abdomen black, the rings 2 to 6 orange with a black macular stripe. In the ♀ the markings are more yellow. Expanse of wings: 38 to 50 mm. Brazil.

C. argentinensis Rothsch. (35 k) resembles the preceding and differs by the abdomen being beneath spotted black, the lower marginal spot extending to the proximal angle of the forewing; the hindwings are mostly more extensively yellow, but the basal black may also increase and be connected with the marginal band by stripes. Expanse of wings: ♂ 36 mm, ♀ 30 mm. Argentina.

C. cynara Drc. (35 k) exhibits, instead of the orange median band, a broad longitudinal stripe from the base as far as beyond the cell; a narrow antemarginal band like in the others. Hindwing black with an orange-yellow stripe in the basal half of the costal margin. Expanse of wings: 36 mm. Mexico.

C. trisigna Wkr. (35 k) is the smallest species. Markings on the forewing similar as in *cynara*, but the longitudinal stripe is divided into 2 small spots. Hindwings orange, with a black margin. Expanse of wings: 24 mm. Venezuela.

C. triplaga Hmps. (35 k). Forewings similarly marked as in *cynara*, but the marginal band is divided into 3 small spots. Hindwing black, with an orange spot in and below the cell. The body is black, the collar orange; abdomen on the 2nd ring subdorsally spotted orange, the others exhibiting orange lateral stripes except the last ring. Expanse of wings: 30 mm. Paraguay.

62. Genus: **Gnamptonychia** Hmps.

Proboscis developed; palpi short, porrect; forehead roughly haired; ♂ antennae serrated and ciliated; anterior tibiae very short with a long, bent hook inside and a shorter one outside; base of abdomen roughly haired. On the forewing the upper median vein rises close at the cell-angle, out of which the two lower radial veins rise, accessory cell present, from the lower bordering of which the upper radial vein rises; the uppermost subcostal vein terminates into the costal margin. On the hindwing the upper median vein is petioled with the lower radial, the middle one is absent, the upper one on a common footstalk with the subcostal.

flavicollis. **G. flavicollis** Drc. (= *tiria* Drc.) (32 i). Dull black, head and collar orange-yellow, so is the last abdominal ring and stripes on the femora. Expanse of wings: ♂ 46 mm, ♀ 34 mm. Mexico.

orsola. **G. orsola** Dyar (32 i) is smaller than the preceding and differs by quite ochreous-yellow ventral side. Thorax and forewings are more slate-coloured, abdomen and hindwings blacker. Expanse of wings: 38 mm. Mexico.

63. Genus: **Inopsis** Fldr.

In its exterior very closely allied to the preceding; the palpi are beneath more strongly haired, the ♂ antennae partly double-combed, partly simply ciliated; anterior tibiae very much like in the preceding genus, posterior tibiae with longer spurs. On the forewing the upper median vein is more remote from the cell-angle; the middle radial rises in the ♂ above the cell-angle, in the ♀ out of it, or petioled with the lower one. On the hindwing the two lower radial veins are petioled and rise with the upper median vein from the lower cell-angle.

Sect. I. ♂ antennae combed.

imitata. **I. imitata** H. Edw. (= *flavicollis* Drc., *tiria* Drc. p. parte) (35 l). Black with a faint blue reflection; palpi, forehead, spots on the collar, hips, venter, and anal tuft in the ♂ orange, in the ♀ the whole collar, vertex, and the greatest part of the legs are orange. Expanse of wings: 36 to 40 mm. Mexico.

catoxantha. **I. catoxantha** Fldr. (= *tiria* Drc. part.) (35 l) is orange on its head and collar, the ventral side, in the ♂ except the abdominal end, likewise. The forewings are more bronze-greenish or greenish-blue than in the preceding; hindwings black with a blue reflection. Expanse of wings: 42 mm. Mexico.

scylla. **I. scylla** Drc. (35 l) differs by its black forehead from the preceding; black with a dull blue shine. The ventral side is likewise orange, in the ♂ not quite to the end. Expanse of wings: 42 mm. Mexico to Panama.

Sect. II. ♂ antennae ciliated.

modulata. **I. modulata** H. Edw. (32 i). Body and forewings metallic bronze-green; head, collar, hips, femora, and venter orange. Hindwings black with a bluish-green shine. Expanse of wings: 40 to 46 mm. Mexico.

metella. **I. metella** Drc. (35 l) differs from the preceding by its black femora; the forewings are of a duller bronze green, the hindwings more blue with a small whitish stripe below the cell-end. Expanse of wings: 48 mm. Guatemala.

64. Genus: **Cyptonychia** Hmps.

Closely allied to the preceding genus; the forehead with a large, round projection, the anterior tibiae only on the inside with a long, bent spine. On the forewing the venation is almost the same, only the upper radial vein rising from below the upper cell-angle, on the hindwing the middle radial vein from above the lower cell-angle.

flaviceps. **C. flaviceps** Drc. (35 l) is orange-yellow on its head and thorax; palpi, chest, legs, and abdomen are brownish-grey. The wings are yellowish-white, the forewings with a basally black costal margin. Expanse of wings: 30 to 34 mm. Mexico.

65. Genus: **Nyctosia** Hmps.

Very similarly built as *Inopsis*, but different by the stunted proboscis and longer palpi. Head, thorax, and base of abdomen are roughly haired; the ♂ antennae serrate and ciliated; on the posterior tarsi there are no middle spurs. Venation likewise similar, but the accessory cell of the forewing is absent, the 4 lower subcostal veins all on a common pedicle, only the uppermost rising from the cell and terminating freely into the costal margin. On the hindwing the upper radial and the subcostal vein rise unpetioled.

coccinea. **N. coccinea** Schs. (35 l). Body black with a faint blue reflection; forewings dull blackish-brownish, hindwings carmine, costal margin and fringes black. Expanse of wings: 38 mm. Mexico.

poecilnotus. **N. poecilnotus** Dyar (35 m). Forehead dark grey, vertex orange, also the thorax; collar and shoulder-covers grey, thoracic sides orange-pink like the first abdominal ring; the rest of the abdomen is bluish-black except the orange anal tuft. Forewings leaden grey, hindwing with a narrow, grey costal margin and border. Expanse of wings: 40 mm. Mexico.

N. tenebrosa Wkr. (= proxima H. Edw.) (35 m). Head, thorax, and the anal tuft of the ♂ orange- *tenebrosa*. yellow, the rest of the body inclusive of the palpi, collar and shoulder-covers bluish-black. Forewings black with a bronze-green lustre, hindwings with a dull blue shine. Expanse of wings: 48 to 52 mm. From Mexico to Guatemala.

66. Genus: **Pygoctenucha** Grt.

Proboscis well developed; palpi rather long, beneath hairy, protruding forward; ♂ antennae with short double combs. Anterior body and base of abdomen roughly haired. The ♀ has dense, woolly hair on the anus. Veins of the forewings as in *Nyctosia*, but with an accessory cell. On the hindwing, in *enna*, the lower radial veins and the upper one are petioled with the subcostal, in the other species not. — 5 species known hitherto.

P. enna Drc. (35 m) has a black body with orange forehead, palpal base, collar, and shoulder- *enna*. covers. In the ♂ also the hair on the 2 last abdominal rings laterally and beneath are orange, in the ♀ whitish. Forewings black with a bronze-green shine. Hindwings hyaline diaphanous with a broad, blackish-green border. Expanse of wings: 40 mm. Mexico.

P. azteca Schs. is smaller and distinguishable by black, not red forehips. The collar, shoulders, *azteca*. anal tuft, and a small spot at the base of the costal margin on the forewing are in the ♂ carmine, in the ♀ orange. Fringes in the ♂ white. Expanse of wings: 38 mm. Mexico.

P. terminalis Wkr. (= pyrrhoura Hulst., votiva Edw., bolteri Edw., harrisii Bsd.) (35 m) is a well *terminalis*. known, common species, on the body black with a metallic blue lustre, and scarlet forehips, collar, shoulders, and anal tuft; the latter is in the ♀ whitish at its extreme end. Forewings black with a green lustre and white fringes; hindwings more bluish lustrous. Expanse of wings: 46 mm. Mexico, common.

P. funerea Grt. (35 l) is a minute, dull black animal, with a very faint blue reflection; lateral spots *funerea*. on the collar, and the abdominal end are yellow. Expanse of wings: 28 mm. United States, Mexico.

P. clita Drc. (35 m) is an entirely different, unicolorously orange-yellow species with longer palpi, *clita*. much more slenderly built, the wings broader, with a narrow accessory cell. Palpal ends and antennae are black. Costa Rica.

67. Genus: **Pronola** Hmps.

Proboscis well developed; palpi erect, not reaching the vertex; ♂ antennae ciliated; tibiae with long spurs. Forewings short and broad, with a strongly curved costal margin. The lower median vein is strongly curved at its rise, the upper one rises before the cell-angle, from which the two lower radial veins rise; the upper one rises below the upper cell-angle, the 4 lower subcostal veins petioled, only the uppermost separately from the cell. On the hindwing the upper median anastomoses with the lower radial vein; the middle radial rises above the lower cell-angle, the upper one anastomoses with the subcostal. The ♂ exhibits beneath in the cell-end and on the lower median vein long scent-hair and above a scent-spot in the cell-end of the hindwing. 5 species are described.

P. magniplaga Schs. (32 h). Head and thorax orange-yellow, abdomen reddish-brown. Forewings *magni-* pinkish-brown with a yellow base, costal margin and border. Hindwing light red-brown, in the costal half *plaga*. light yellow, in the ♀ darker. In the latter the apex is broader yellow. Expanse of wings: 20 mm. Brazil, Bolivia.

P. fraterna Schs. is very similar, smaller, and the reddish-brown parts of the preceding are here *fraterna*. violettish-black. Expanse of wings: 16 mm. French Guiana (Maroni River).

P. diffusa Schs. (32 h) is likewise similar, paler yellowish, the greyish-brown inner-marginal area is *diffusa*. in the cell deeply incised by the yellow costal margin and has a yellow middle-spot. Hindwings pale yellow. Peru.

P. ectrocta Dogn. (32 h). Head, thorax, and abdomen yellow, the latter two above mixed with brown. *ectrocta*. Forewings yellow with a large, U-shaped brown spot broadly bordering on the proximal margin. Hindwings light yellow. Colombia.

P. perdifusa Dogn. (32 h) is more slenderly built, with more extended forewings exhibiting in the *perdifusa*. ♂ beneath in the cell a roughly haired excavation; above it there are black scent-scales, in the cell-end a silvery lustrous, black hair-tuft, and a hairy oblique stripe crosses the lower median vein. The body is yellow-brownish, the forewings yellow with reddish-brown nebulous bands before and behind the middle. Hindwings light yellow. Colombia.

68. Genus: **Eugonosia** Hmps.

Distinguished by the entirely stunted proboscis and palpi; posterior tarsi with moderately long spurs. On the forewing the upper median vein rises petioled with the lower radial from the lower cell-angle; above it the middle radial comes forth; the upper one is petioled with the 3 lower subcostal veins, the two upper ones terminate into the costal margin. On the hindwing there are quite the same conditions, the upper radial on a very long footstalk with the subcostal vein. Only 1 species known.

E. angulifer Schs. (36 a). Head and thorax orange, overflowed with pink, abdomen rosy red; antennae *angulifer*. blackish-brown, curled white. Forewings orange, tinted rosy, with black margins and a black angular marking being open downward. Hindwings rosy with orange fringes. Expanse of wings: 24 mm. Brazil: Castro (Paraná).

69. Genus: **Rhodographa** Hmps.

Differs from the preceding only by the fully developed proboscis and somewhat longer, porrect palpi. Venation on the whole the same, but on the forewing the lower median vein is placed somewhat nearer to the lower cell-angle, and on the hindwing the footstalk of the lower radial vein is longer.

phaeoplaga. **R. phaeoplaga** Schs. (= *schistaceoplagiata* Rothsch.) (36 a) is a very small, orange-yellow animal with a carmine head and thorax. The orange-yellow forewings, being dotted carmine at the base and before the margin, exhibit in the middle a very large, blackish-brown spot margined with carmine. Hindwings orange, slightly tinted red. Expanse of wings: 18 mm. Known from Brazil and Bolivia. For the synonym the genus: *Neothyone* was established, the description of which corresponds in the venation to *Rhodographa*, comp. p. 266.

70. Genus: **Nudosia** Hmps.

Proboscis absent; palpi very short; ♂ antennae finely serrate and ciliated; posterior tibiae without any middle spurs. On the forewing the median and radial veins rise all separately; only the two lowest subcostal veins are petioled, the 3rd is absent, the 2nd comes from the cell, and the uppermost anastomoses with the costal. On the hindwing the upper median and lower radial vein are anastomosing, like the upper radial and the subcostal vein.

fuscifusa. **N. fuscifusa** Hmps. (36 a). The only small species looks very much like the *Pronola*-species in its exterior. Light orange-yellow, with a large, blackish-brown discal spot as far as the proximal margin, projecting distally in the middle of the distal margin and being finely veined yellow. Hindwings light yellow, in the disc tinted greyish-brown. Vertex whitish. Expanse of wings: 18 mm. Peru.

71. Genus: **Achroeosia** Hmps.

Very much like the preceding; antennae in the ♂ doubly combed. The venation almost the same, on the forewing the 3rd subcostal vein is present and petioled together with the lower ones. On the hindwing the lower radial vein is likewise present and rises separately from the cell-angle, the middle one above it; the rest as in *Nudosia*. Only one, insignificant species:

nuda. **A. nuda** Hmps. (36 a). White. The wings very thinly scaled and diaphanous; margin of the forewing ochreous-yellow, brownish towards the base. Antennae and legs yellowish. Expanse of wings: 18 mm. Brazil.

72. Genus: **Castronia** Jones.

Proboscis stunted; palpi very short, porrect; male antennae long-combed; posterior tibiae with 2 pair of very short spurs. On the forewing the venation is like in *Nudosia*, on the hindwing all the veins are present separately, the lower radial vein comes from above the lower cell-angle. Likewise only 1 species:

apostata. **C. apostata** Schs. (= *collaris* Jones) (36 a). Body blackish-brown; 2 spots on the hindhead, and the collar are yellow, so are lateral stripes and the apex of the abdomen. Forewings diaphanous brown, the veins and a fine marginal line darker. Hindwings blackish-brown. Expanse of wings: 32 mm. Brazil: Castro (Paraná).

73. Genus: **Comacla** Wkr.

This otherwise palearctic genus contains in America only 2 representatives very much like each other, with doubly combed antennae, stunted proboscis, and longer palpi than the preceding genera. The abdomen is roughly haired. Veins of the forewings exactly like in *Achroeosia*, but the uppermost subcostal vein runs separately and does not anastomose with the costal. On the hindwing the upper median vein rises far before the cell-angle, out of which the lower radial rises, the middle one above it; the upper one rises with the subcostal vein from the upper cell-angle.

simplex. **C. simplex** Wkr. (= *murina* Wkr., *clarus* Grt., *texana* French) (36 a) is light brownish on its body and wings, the latter being very thinly scaled and diaphanous, the forewing at the base with a small yellow spot; small, orange-yellow spots are also on the head and shoulders. Abdomen above yellow. Expanse of wings: ♂ 22 mm, ♀ 28 mm. United States: Florida.

fuscipes. **C. fuscipes** Grt. differs from *simplex* by its grey abdomen, broader forewings strewn more profusely dark, more shortly combed antennae. Expanse of wings: 22 mm. Arizona.

74. Genus: **Balbura** Wkr.

Proboscis developed; palpi erect, reaching to the vertex, and hairy below at the basal joint. Antennae of the ♂ doubly short-combed, towards the tips serrate. On the forewing the upper median vein rises before the cell-angle, out of which the two lower radial veins rise, the upper one from the upper angle; the uppermost subcostal vein anastomoses with the costal. On the hindwing the two lower radial veins and the upper one are petioled with the subcostal or also unpetholed. Hitherto 3 species have been described:

B. dorsisigna *Wkr.* (32 i) is a widely distributed and common insect, with greyish-brown, darker *dorsisigna*, veined forewings with an orange-red base; the collar and thorax are orange-red, too. Expanse of wings: 30 mm. Honduras; Panama; Venezuela.

B. fasciata *Schs.* (32 i). Body black, with red shoulder-covers and base of forewing. Forewings *fasciata*, otherwise light brownish, at the costal and proximal margins, and on the cellular and submedian folds striped black; at the cell-end there is a broad, blackish-brown transverse vein; in the marginal area long, black internerval stripes; the one between the upper radial veins extends to the cell. Hindwings dark brown. Expanse of wings: 34 mm. Costa Rica.

B. intervenata *Schs.* (36 a). Body black with a red thorax; shoulder-covers outside bordered with *intervenata*, black. Forewings blackish-brown, with a broad, black proximal margin; in the marginal area black intermediary stripes, like in the preceding, and the third uppermost likewise extends as far as the cell. Hindwing black, in the disc diaphanous. Expanse of wings: 27 mm. Costa Rica.

75. Genus: **Lithoprocris** *Hmps.*

Differs from the preceding by shorter, porrect palpi covered below with long scales. Antennae above in the middle covered with scales. On the forewing the middle radial vein rises above the lower cell-angle, the upper one below the upper cell-angle; all the rest like in *Balbura*.

L. methyalea *Hmps.* (36 a). Anterior body and forewings of a metallic bluish-green; abdomen and *methyalea*, hindwings more blue, the latter in the basal half of the proximal margin hyaline. Expanse of wings: 30 mm. Bolivia.

L. hamon *Drc.* (36 b) is no *Syntomida*, but belongs hereto. Head and thorax are coppery brown, the *hamon*, abdomen metallic blue. Forewings coppery golden, at the base suffused with purple. Hindwings purple blue, at the costal margin brown, in and below the cell there is a hyaline spot. Expanse of wings: 32 mm. Peru.

L. postcoerulescens *Rothsch.* (36 b) deviates by the peculiar formation of the hindwing: the costal *postcoerulescens*, margin is very convex, on the upper surface there is below the cell a fold with a hyaline border on both sides, the proximal margin is provided with very long brown fringes, on the under surface an ochreous-yellow scent-scale spot extends from the lower cell-angle to the margin, the proximal margin is turned over, covered with brown scales of a silvery gloss, below the median there is another roughly scaled, oval, black spot. Body and wings are metallic green, the forewings towards the margin blue. Perhaps it is the ♂ of *jason*. Expanse of wings: 22 mm. Peru.

L. jason *Dogn.* is much smaller, on the body metallic blue, forewings golden green, at the base, costal *jason*, margin and distal margin lustrous blue; hindwings greenish black. Expanse of wings: 26 mm. Ecuador.

76. Genus: **Dipaena** *Wkr.*

Proboscis developed; the erect palpi extend to the vertex, below long haired except the terminal joint. The antennae are often thickened in the middle, mostly here on top covered with long scales, otherwise with ciliary bristles. Spurs of tibiae short. On the forewing the upper median vein rises below the cell-angle, out of which the lower radial vein rises, the middle one above it, the upper one below the upper angle. The subcostal veins like in the preceding. The proximal margin exhibits in the ♂ in the middle long hair. On the hindwing the two lower radial veins rise from the lower cell-angle, or the middle one also from above it, the upper one being petioled with the subcostal vein. 6 species are known so far:

D. acharon *Wkr.* (= *ferruginosa* *Wkr.*, *rhodura* *Btlr.*) (32 h) is on the body blackish-brown, with *acharon*, a blue and purple reflection, the 3 last abdominal rings above scarlet, in the ♀ less so; the anal tuft of the ♂ is only below red. Forewings with a purple reflection, at the costal and proximal margins suffused with a metallic bluish-green. Hindwings diaphanous, in the ♂ with a reddish-yellow scent-spot in the cell-end, at the margin broadly purple blue. Expanse of wings: 30 mm. Amazon District.

D. contenta *Wkr.* (= *lateralis* *Wkr.*, *squamicornis* *Fldr.*) (32 h) is similar, but the abdomen is above *contenta*, scarlet in its whole length, on the sides of the middle rings the ground-colour projects somewhat into the red. On the hindwing the diaphanous basal part is greatly confined; the ♂ is without the scent-spot. Expanse of wings: 28 mm. Amazon.

D. incontenta *Schs.* (36 b) is much smaller, on the wings dark red-brown, suffused with violet, parti- *incontenta*, cularly at the proximal margin. Hindwings greyish-black, towards the margin dark blue. On the abdomen only the 2 last rings are red above and laterally. Expanse of wings: 22 mm. Colombia.

D. eucera *Fldr.* (36 b). In the following species the antennae are not thickened, and the scaly cover *eucera*, is only short. Head and thorax black, palpi, collar and shoulder-covers orange-yellow; abdomen orange with a black dorsal stripe, the last rings quite black. Forewings black with a coppery lustre. A spot at the base of the proximal margin, and an oblique postmedian band are orange. Hindwings orange with a black margin. Expanse of wings: 22 mm. Colombia.

moesta. **D. moesta** Wkr. (36 b). Body and forewings blackish-brown with a faint blue shine. Hindwings blackish-brown. Anal tuft earmine. Expanse of wings: 28 mm. Habitat unknown.

salcedo. **D. salcedo** Dogn. (36 b) deviates from the other species by the broad shape of its hindwings which are in the ♂ greatly prolonged at the anal angle, as well as by long, orange-yellow hair-tufts on the 2nd abdominal ring. The ♀ is unicolorously black with a blue and purple reflection; in the ♂ the hindwings are diaphanous below the base of the cell, and the 4 last abdominal rings beneath banded orange. Expanse of wings: 30 mm. Panama, Ecuador.

77. Genus: **Cloësia** Hmps.

Very much like the preceding genus, the palpi shorter, the antennae not thickened and without any scales. On the forewing the venation is almost the same as in *Dipaena*, but the two lower radial veins rise from the same place. On the hindwing the middle radial comes from above the lower cell-angle; the costal vein is strongly curved.

parthia. **C. parthia** Drc. (36 b). Head and thorax dark metallic bluish-green, the abdomen more purple blue. Forewings metallic golden green, hindwings bluish-green. Expanse of wings: 34 mm. Known from Nicaragua, Panama and Brazil.

digna. **C. digna** Schs. (36 c) is much smaller, on its body and forewings metallic blue. The hindwings are thinly scaled, brownish-black with metallic blue stripes at the proximal margin, along the lower median vein and below the apex. Expanse of wings: 28 mm. Costa Rica.

normalis. **C. normalis** Dogn. (36 c). Body deep metallic green, the shoulder-covers with long pale green hair. Forewings above dull violettish-blue; hindwings and under surface metallic blue. Expanse of wings: 35 mm. Colombia.

78. Genus: **Eudolie** Mschlr.

Proboscis stunted; the short palpi porrect. ♂ antennae sealed; legs and abdomen roughly haired. Veins of the forewing similar as in *Dipaena*, but the upper radial vein is petioled with the 3 lower subeostal veins, the uppermost of which does not anastomose with the costal. On the hindwing the middle radial is absent. Only 3 species:

vittata. **E. vittata** Mschlr. (= *achatina* Btlr., *rufitineta* Rothsch.) (36 e) has a white body, the abdomen posteriorly darkened by brownish-grey; on the metathorax red-brown. Forewings white, in the whole disc as far as the proximal margin clouded red-brown with a white discal spot which is absent in the ♀, some dots at the costal margin, and before the apex at the margin 2 small spots. At the proximal margin of the ♂ a brownish-grey stripe. Hindwings white, in the ♂ before the margin darkened. Expanse of wings: 20 mm. Surinam. to the Amazon.

longa. **E. longa** Schs. (36 c). Head and thorax white, abdomen tinted reddish-yellow. Forewings white; at the base of the proximal margin a brown shade, one in the middle of the cell, one below it cohering with another, postmedian shade, which touches neither the costal margin nor the proximal margin; at the margin there are 3 small, brown spots: at the apex, in the middle, and at the proximal angle. Hindwings and fringes white. Expanse of wings: 22 mm. French Guiana.

major. **E. major** Rothsch. (36 c) almost looks like an *Areva*. The body is white, mixed with reddish-brown. Forewings whitish with faded red-brown spots. Hindwings with a very faint, reddish-brown tinge. Expanse of wings: 34 mm. Peru.

79. Genus: **Dolichesia** Schs.

Proboscis well developed; the porrect palpi project beyond the forehead; ♀ antennae flattened, scaled. The posterior tibiae are without any middle spurs. Forewings long and narrow with a falciformly curved costal margin. The upper median vein rises far before the cell-angle, out of it the lower radial vein and a little higher up the middle radial; the upper one comes from the upper cell-angle; the 3 lowest subeostal veins on one footstalk, the uppermost anastomoses with the costal. On the hindwing the middle radial is absent, the upper one anastomoses with the subcostal.

falsimonia. **D. falsimonia** Schs. (36 c). Head and thorax greyish-brown, abdomen pink. Forewings greyish-brown with a curved, light-grey shade from the middle of the costal margin almost to the base of the proximal margin, behind it a dark brown, oblique streak from the cell to the proximal margin; a light red-brown line runs from the costal margin before the apex to the margin at the lower radial; at the margin there are small black spots which flow together towards the proximal angle and pass over to the fringes; fringes otherwise white, at the apex black. Hindwings pink with a broad black border growing narrower towards the proximal angle. Expanse of wings: 16 mm. Costa Rica.

lignaria. **D. lignaria** Rothsch. (33 g) has not the falciform apex of the forewing as the preceding. Anterior body light reddish-brown, abdomen carmine with a black anal tuft. Forewings light reddish-brown, strewn darker, with indistinct, darker, antemedian, median and postmedian nebulous lines. Hindwings carmine-rosy with a blackish-brown marginal band. Expanse of wings: 20 mm. Peru.

80. Genus: **Macroptila** Dogn.

The 7 species known hitherto of this genus approximate the *Agylla* already by the shape and thereby our *Lithosia*; the forewings are almost lancet-shaped, and the hindwings in some species, such as *antonia* and *extensa* extraordinarily large. Proboscis developed. Palpi erect, beneath covered with hair which is turned downward. On the long, narrow forewing the lower median vein rises behind the middle of the cell; the upper one before the cell-angle; the two lower radial veins are petioled, the upper one either from the upper cell-angle or from below it; the uppermost subcostal vein is curved and terminates into the costal vein; in the ♂ the costal margin beneath is hairy. Hindwings very broad and round; the lower median vein from the middle of the cell; the upper one close in front of the lower angle; the two lower radial veins petioled or unpetioled, similar as the upper one with the subcostal.

M. monstralis Schs. (36 i). Head and thorax grey, forehead brown; abdomen whitish; legs white, *monstralis*. anterior tibiae above with ochreous-yellow hair. Forewings light grey, towards the proximal margin darker grey, costal margin and the veins above the median veins white; costa itself ochreous-yellow. Hindwings in the costal-marginal half light brown, towards the proximal margin white; margin dark grey from the lower median vein to the apex. In the base of the cell a small scent-scale spot. The costal margin of the forewing is straight and exhibits before the apex a small, lobular embayment. Expanse of wings: 30 mm. Costa Rica.

M. antonia Dogn. Body yellowish-white. Forewing of the ♂ in the disc with a scent-scale spot, at *antonia*. the lower cell-end a tuft of long white hair, lustrous silvery white, costa finely ochreous yellow. Hindwings above white. Under surface white, in the marginal area of the forewing and in the costal half of the hindwing with a grey tinge. In the ♀ also the proximal margin of the forewing is above tinged grey. Expanse of wings: ♂ 38 to 40 mm, ♀ 31 to 33 mm. Colombia.

M. crinada Dogn. (36 i) has a greyish-brown head and thorax; antennae red-yellow; abdomen yellowish *crinada*. white with an orange anal tuft. The white forewings are tinged purple grey towards the proximal margin and exhibit a similar stripe above the lower median vein; costal margin yellowish, towards the base darkened. Hindwings yellowish-white, towards the margin tinged greyish-brown, in the ♂ with a large scent-scale spot in the costal area. The ♀ is of a purer white with a decidedly darker inner-marginal band. Expanse of wings: 44 mm. Ecuador.

M. laniata Dogn. (37 l). Body white, tinged greyish-brown; antennae, legs, last abdominal ring, and *laniata*. ventral side ochreous-yellowish. Forewings silvery white, dusted darker; the ♂ exhibits beneath in the disc tufts of very long yellowish-white hairy scales. Hindwing in the costal half greyish-brown, in the inner-marginal half white. Expanse of wings: 34 mm. Ecuador.

M. nubecula Schs. (37 l) deviates from the other species by the narrower cell of the forewing and curved *nubecula*. median; the uppermost radial vein rises far below the upper cell-angle. The hindwing exhibits in the ♂ a large, brown scent-scale spot in the cell; the upper median vein is petioled with the lower radial veins; the costal margin is concavely excised before the apex. Head and thorax are lilac grey, the abdomen reddish-white. Forewings in the costal-marginal half silvery white, delicately laid on with yellow-reddish, below the cell lilac grey, with a yellow-reddish hue. Hindwings yellow-reddish white, towards the apex dusted grey. Expanse of wings: 32 mm. Costa Rica (Sixola, Tuis, Esperanza).

M. extensa Roths. (37 l) is described according to 1 female specimen. Body light red-brown, mixed *extensa*. with whitish. Forewings silvery white, proximal margin tinged reddish-brown. Expanse of wings: 42 mm. Peru.

M. fuscilaniata Hmps. (37 l) is distinguished by very broad wings. Body ochreous-yellow, on the *fuscilaniata*. head and thorax brownish. The ochreous-yellowish forewings are tinged blackish-brown at the proximal margin, costal margin towards the base blackened. Hindwings ochreous-yellow, towards the costal margin brownish. Beneath the forewings exhibit above the proximal margin a blackish-brown scent-spot, above it yellow spatulate scales. The ♀ has plain white wings with a brownish proximal margin. Expanse of wings: ♂ 40, ♀ 46 mm. Colombia.

81. Genus: **Hypareva** Hmps.

Proboscis well developed. Palpi rather short, covered with hair turned downward; ♂ antennae at the base thickened, with long ciliary bristles. Anterior femora long-haired. The venation differs little from that of the preceding genus; the two upper subcostal veins of the forewing rise freely from the cell and run into the costal margin. The upper radial vein and the subcostal of the hindwing are unpetioled. The ♂ exhibits beneath on the forewing long hair in the cell and in the submedian space, and a large pouch in the basal part of the median of the hindwing. Only 1 species is known:

H. pogonoda Hmps. (= *laticilia* Drc. part.) (37 l). Body and wings white, the head ochreous yellow, *pogonoda*. Forewings at the costal margin brownish, at the proximal margin dusted more purple blackish, in the ♀ more intensely than in the ♂. In the latter the hair on the under surface are ochreous-yellow. Expanse of wings: 32 mm. Distributed from Mexico through Guatemala, Panama as far as Guiana (Cayenne).

82. Genus: **Aptilosia** Schs.

Proboscis developed. Antennae in the ♂ with short cilia. Abdomen with rough hair. Forewings rather broad. Venation similar as in the preceding; on the forewing the two lower radial veins rise from the same place

of the lower cell-angle, the uppermost subcostal vein anastomoses with the costal. Hindwings broad, costal margin very convex, apex rounded; the margin runs almost in a straight line to the proximal angle. In the cell of the ♂ a large scent-scale spot; the middle radial rises separately from the lower one above the cell-angle, the upper radial anastomosing with the subcostal vein. Only 1 small species.

crocea. **A. crocea** Schs. (371). Head and thorax lilac-grey; the abdomen like the wings yellowish-white, the proximal margin of the forewing broadly lilac grey; on the hindwing a stripe of long yellow hair runs along on the median. Expanse of wings: 29 mm. Costa Rica.

83. Genus: **Tricharesa** Hmps.

Distinguished from the preceding genus by the somewhat rounder shape of the wings and, above all, by the lower radial veins being rather long petioled on all the wings; on the hindwing the upper radial vein is present separately. The ♂ exhibits on the forewing beneath hairy fringes in a costal fold, and long erect hair along the submedian fold, on the hindwing above in the cell-end a tuft of fluffy hair.

fulvilaniata. **T. fulvilaniata** Dogn. (371) is on its body white, with a brownish hue, the antennae more red-yellow. Forewings silvery white, at the proximal margin light brown, the costal margin towards the base blackened; hindwing white with a red-yellow woolly hair-spot. Expanse of wings: 28 mm. Panama.

84. Genus: **Hyperthagylla** Hmps.

Likewise closely allied to the preceding genera. Forewings narrower, with a narrow discocellular, beneath without any hair; a small accessory cell is present and is produced by the 3rd subcostal vein anastomosing with the 4th; the 1st subcostal vein is separated. Hindwings more rounded, the two lower radials on a short pedicle; in and behind the cell-end of the ♂ a large scent-scale spot. On the last abdominal ring of the ♂ very long lateral hair-tufts. Contains but 1 species.

mira. **H. mira** Btlr. (361). White, on its body, costal margin and proximal margin of the forewing tinged lilac grey. The scent-spot of the hindwing red-brown. Expanse of wings: 26 mm. Amazon District.

85. Genus: **Metagylla** Hmps.

Only 1 species. Distinguished from the preceding genus by the palpi being provided with hair turned downward, and still longer hairing, also on the dorsum of the anal segment of the ♂. The venation is likewise very similar; on the forewing the upper median vein is removed to the cell-angle, so that it rises from the same place with the two lower radials; the accessory cell is absent. On the hindwing the upper median vein is on a short pedicle with the two lower radials. The other venation and the scent-spot as in *Hyperthagylla*.

miroides. **M. miroides** Hmps. (361) is coloured almost exactly like *mira*, only the dorsal anal tuft is reddish-yellow, the lateral ones being blackish-brown. The red-brown scent-spot is distally bordered with ochreous-yellow. Expanse of wings: 28 mm. Costa Rica.

86. Gattung: **Agylla** Wkr.

Proboscis developed; the erect palpi do not reach the vertex; posterior tarsi with spurs of medium length; abdomen at the base covered with rough hair. Forewings rather narrow; the lower median vein rises close behind the middle of the cell, the upper one rather far before the lower angle; the two lower radial veins either on a short footstalk, or from the cell-angle; the upper radial comes out of the upper cell-angle or the accessory cell which is produced by the 3rd subcostal vein anastomosing with the 4th; the uppermost subcostal vein separately from the cell and terminating in to the costal margin. On the hindwing the upper median vein rises from the cell-angle or close before it; the two lower radials like on the forewing; also the upper one is either petioled with the subcostal or it comes separately out of the cell-angle. As to further particulars about this genus comp. Vol. II, p. 64, and Vol. X, p. 199.

A large genus, distributed in all parts of the globe, except Europe. The American representatives are preferably coloured white, often with a darkened proximal margin of the forewing. Many species are distinguished by secondary sexual marks, mostly consisting in the ♂♂ of scent-scale spots or varied hairing. ♂ antennae either doubly short-combed, or also with ciliary bristles. Of late a great number of species have been described, all of which are mostly very much like each other and make it difficult to define them; this is particularly the case in the ♀♀, since the ♂♂ can be better distinguished by the various hairy spots on the wings or tufts on the abdomen etc. In the neotropical region they represent our *Lithosia* which they also resemble on the whole in their habits. Like them, they have the narrow long forewings turned round the mostly much too large hindwings being folded together and round the abdomen. The species come to the lamp.

Sect. A. ♂ antenna doubly combed. towards the apex dentate.

A. foyi Dogn. (36 l). An easily recognizable, large species. Head, collar and anterior half of the thorax *foyi*. metallic green, thorax posteriorly silvery white; palpi orange with a black terminal joint; chest, legs and abdomen orange; anterior tibiae and tarsi striped green. Forewing silvery white with an orange-yellow costa and a fine blackish green stripe on the inner-marginal vein; hindwings dull white. Expanse of wings: 50 mm. Ecuador.

A. argentifera Wkr. (37 a) is quite silvery white with orange palpi, legs and antennae, the palpal *argentifera*. terminal joint and forehead being black. Collar blackish, abdomen above tinted ochreous-yellowish; in the ♂ the costa of the forewing is orange and a dark spot at the proximal margin, both being absent in the ♀. Expanse of wings: 46 to 52 mm. Mexico, Costa Rica, Venezuela, Brazil.

A. marcata Schs. (37 a) resembles *argentifera*, though it is smaller; thorax darker; shoulder-covers *marcata*. with an orange spot. Abdomen orange, only above in the middle white. The dark inner-marginal spot of the forewing is in the basal half divided by a white longitudinal stripe. In the ♀ the abdomen is almost white and above the dark inner-marginal spot there is an orange stripe. Expanse of wings: 40 mm. Brazil to Peru.

A. fusciceps Hmps. (37 a). Head and collar blackish-brown, thorax white, antennae reddish-yellow; *fusciceps*. abdomen white, with a brownish hue; palpi and the whole underside, inclusive of the legs, orange, anterior tibiae and tarsi anteriorly brown. Forewings white, at the proximal margin light brown with an orange proximal margin. Hindwings white, with a faint yellowish hue. The ♀ differs by its white head and collar, the latter showing only one dark median spot. Forewings all white, also the costal margin, only the inner-marginal vein is somewhat brownish. Expanse of wings: ♂ 40 mm, ♀ 44 mm. Colombia, Peru.

A. fulvithorax Hmps. (37 b). Head white, with orange-yellow antennae and a blackish-brown streak *fulvithorax*. between them; palpi, collar, and shoulder-covers orange. Thorax white, anteriorly brownish; legs and abdomen orange. Forewing silvery white, with an orange costal margin. Expanse of wings: 44 mm. Colombia.

A. subochrea Dogn. (37 a) differs from the preceding by its orange-yellow head, with a brown vertex *subochrea*. and entirely white thorax; the abdomen is above lighter yellowish. Wings like in the preceding. Expanse of wings: 46 mm. Colombia.

A. nitidalis Maass. (= *nochiza* Hmps. p. part.) (37 b) is somewhat smaller than *nochiza*; only the *nitidalis*. head and collar are blackish-brown, the thorax white, with a faint yellowish tint. Abdomen above brownish, beneath ochreous-yellow. Wings as in *nochiza* (37 b), but the blackish-brown stripes on the median and its branches, as well as of the costal base are absent. Expanse of wings: ♂ 40 mm, ♀ 44 mm. Colombia, Ecuador, Bolivia, Peru.

A. eriodes Hmps. (37 b) is a large species, with very broad wings, the body white, with a brownish *eriodes*. hue, beneath orange haired. Forewing above silvery white, with an orange costal margin and a faintly brownish proximal margin, beneath with woolly hair on the submedian fold and a longhaired cell. Hindwing white, above the cell is covered with orange-yellow woolly hair. Expanse of wings: 46 mm. Peru.

A. delicia Schs. Much smaller than the preceding. Head and thorax dark grey, abdomen whitish, *delicia*. with a yellow-reddish anal tuft. Forewings white, the proximal half as far as the median smoky grey. Hindwings yellow-reddish, proximal margin and the space before the margin white, distal margin grey, towards the costa darker. Beneath the forewings are grey, the hindwings white, the basal costal-marginal half of both wings reddish-yellow. Expanse of wings: 23 mm. French Guiana.

A. zucarina Dogn. (37 b) has an entirely black head with orange palpi, also antennae, collar and *zucarina*. shoulders are orange, like the chest and legs; the rest of the thorax is white, the abdomen ochreous, above towards the base with grey hair. Hindwings lustrous silvery white, with an orange costa, hindwings lustreless white. The under surface is tinged greyish-brown. Expanse of wings: 34 mm. Ecuador (Loja).

A. nivea Wkr. (= *monoleuca* Wkr.) (37 c) is a very common and widely distributed species. Body *nivea*. and wings silvery white. Palpi orange, with a black terminal joint; forehead blackish, vertex white or orange-yellow, antennae orange, so are the legs, which are partly striped black. Abdomen white, light yellow or orange-yellow. Costa of the forewing in the ♂ orange, in the ♀ white. — The form in which the collar and anterior half of the thorax, inclusive of the anterior half of the shoulder-covers, are tinged brownishgrey, is called: **argentea** Fldr. (= *virginea* Schs.), if the vertex is orange-yellow, — **floreccilla** Dogn. if it is coloured brownish-grey. — **plateada** Dogn. is quite a different form, in which the collar and anterior half of the thorax and shoulder-covers are coloured metallic green. Expanse of wings: 30 to 48 mm. Distributed from Mexico through the whole of Central America as far as Ecuador and Bolivia. *argentea*. *floreccilla*. *plateada*.

A. nochiza Dogn. (37 b) is white, tinted ochreous; forehead and thorax suffused with blackish-brown. *nochiza*. Forewings with blackish-brown stripes on the costal base, the median and its branches; of the same colour a spot at the cell-end and 2 spots at the proximal margin. In the ♀ the ground colour is white, dusted dark brown, the inner-marginal spots more faded. Expanse of wings: 48 to 56 mm. Ecuador, Bolivia.

A. zopisa Dogn. (37 c) has a brown body, being orange-yellow beneath and at the end; palpi orange, *zopisa*. with a black terminal joint. The grey forewings are very densely strewn with blackish-brown scales, the base whitish. Hindwings yellowish-white. Expanse of wings: 42 mm. Ecuador (Loja).

Sect. B. ♂ antenna with ciliary bristles.

- perpensa*. **A. perpensa** Schs. (= *laticilia* Drc. part. nec *Wkr.*) (36 k) is white on its body and wings, abdomen beneath with orange hair-tufts; palpi and legs blackish-brown, the costa of the forewing is covered with short red-yellow hair, the inner-marginal half dusted blackish-brown, the same on the under surface the marginal area of the forewing and the costal-marginal part of the hindwing. The under surface of the forewing shows in the cell a large, orange scent-scale spot and below it tufts of long, orange, rough scales; a similar spot on the hindwing above in and behind the cell. Expanse of wings: 36 mm. From Mexico (Jalapa, Misantla, Vera Cruz).
- tumidicosta*. **A. tumidicosta** Hmps. (= *laticilia* Drc. part. nec *Wkr.*) (36 k). Similarly coloured as *perpensa*, but the under surface brown, only the anal tuft orange. The costal margin of the forewing in the ♂ is bulged out near the base, in the middle turned over downward, and thereby appearing concave, towards the base with short blackish hair. Underneath the forewing exhibits a stripe of long, erect, orange-yellow hair below the cell and the hindwing similar hair above along the subcostal. The ♀ has narrower wings and a narrower brownish-grey proximal margin. Expanse of wings: 32 to 36 mm. Guatemala.
- argentea*. **A. argentea** Wkr. (37 c). White, head and thorax blackish-brownish, abdomen tinted ochreous-yellow; long hair-tufts on the anterior femora and on the ventral side orange. Forewing white, in the inner-marginal half blackish-brown, in the ♂ the costa with orange hair. Beneath the forewing is covered at the end of the median with long, dark brown, towards the base more orange-yellow hair, the marginal area blackish-brownish. Hindwing white, in the disc ochreous-yellow, the cell covered with orange-yellow, woolly hair. In the ♀ the dark inner-marginal area is narrower. — **A. vestalis** Schs. has the marginal area of the forewing beneath all white, and mostly an orange-yellow hair-spot in the disc of it. Expanse of wings: 36 to 46 mm. Brazil.
- oediphebia*. **A. oediphebia** Hmps. (37 c) is marked by a round, knob-like, brown swelling on the median of the forewing beneath near the cell-end and ochreous-yellow scent-scales in the inner-marginal half, on the hindwing above in the costal half. The body is moreover white, with a brown hue; the wings silvery white, at the proximal margin broadly brown. Expanse of wings: 30 mm. Ecuador.
- megasema*. **A. megasema** Hmps. (37 c) is very similar, larger. The swelling on the median is elliptic, much larger, extending from the discal fold to the lower median vein. Body and wings are likewise similar, but the hindwing above, in the costal half, light orange brownish. Expanse of wings: 34 mm. Peru.
- exscissa*. **A. exscissa** Schs. (37 c). Head and thorax smoky grey, forehead and abdomen more yellow-reddish grey. Forewings distally narrow; in the basal two thirds the proximal margin is strongly lobed as far as the retracted inosculature of the lower median vein; the distal third runs straight to the proximal angle, into which the upper median vein terminates; the colour is a silvery white, the inner-marginal lobe brownish-grey, the costa ochreous-yellow. The hindwings are broad, with a rounded margin, silvery white; a large, yellow scent-scale spot in the cell-base is covered by the inner-marginal lobe; below and behind the cell the wing is yellow-brownish, with a brownish-grey postmedian shade above the lower median vein. Beneath the discal part of the forewing is covered with rough, yellow scales, below the cell a cinnamonbrown scent-scale stripe extends; distal margin brownish-grey. Under surface of hindwings blackish-brown; proximal margin and border whitish. Costa Rica.
- barbicosta*. **A. barbicosta** Hmps. (36 k) has no scent-scale spots, only the costal margin of the forewing is blackish-haired in the ♂. White; head and thorax smoky grey; the larger, basal part of the forewing is tinted yellow-brownish, in the terminal third of the proximal margin there is a blackish-brown spot. Hindwings white, in the basal half yellowish. Expanse of wings: 32 mm. Brazil (Rio de Janeiro).
- albivenis*. **A. albivenis** Schs. (36 k). Head and thorax are dark greyish-brown, the forehead yellow-reddish; palpi dark brown, white haired. Abdomen above grey, hairtufts beneath and laterally reddish-white. Legs white, partly striped grey; anterior tibiae black with white rings. Forewings light grey, the veins and discocellular silvery white, the inner-marginal area smoky grey; at the cell-end and between and above the median veins the grey colour is darker; in the ♂ the costal margin exhibits brownish hair. Hindwings white, at the costal margin and border tinged smoky grey. Beneath the forewings are smoky grey, distally lighter, hindwings white, at the costal margin yellow-reddish. In the ♀ the forehead is white, also the forewings entirely white, only between the median veins near the cell tinted grey; the proximal margin dark brownish-grey. Expanse of wings: 26 to 28 mm. Costa Rica.
- polysemata*. **A. polysemata** Schs. (37 d) has much broader wings than the preceding. White, the body with a smoky grey tinge; proximal margin of the forewing dusted smoky grey. Costa towards the base blackish. The ♂ shows beneath a hairy costal fold, below the cell a light reddish-yellow hair-stripe, being still much longer haired on the lower median vein. Hindwings towards the margins somewhat brownish, beneath with white, woolly hair in the cell and with brown hair above it, and a black scent-scale spot below it. The ♀ has more purely white wings. Brazil.
- auranticaria*. **A. aurantaria** Schs. (36 k). Body above grey, beneath yellow-reddish white. Forewings white, at the proximal margin faintly grey. Hindwings white, with a large scent-scale spot in the basal half of the cell, and a grey shade on the lower median vein at the margin. Beneath the forewing exhibits below the cell a stripe of hair which grow much longer between and above the median veins, like in the preceding species. Expanse of wings: 26 mm. French Guiana.
- fasciculata*. **A. fasciculata** Wkr. (= *hypotricha* Fldr.) (36 l) is purely white; palpal terminal joint black; legs brownish. The ♂ exhibits beneath on the median of the forewing rough, ochreous-yellow hair, on the upper surface of the hindwing in the cell and somewhat behind it woolly, yellow hairing. Expanse of wings: 30 mm. Venezuela.

A. barbula Dogn. (37 d) is distinguished by much longer discocellulars of both wings; on the hind- *barbula*. wing the two lower radial veins rise from the same place. Head and thorax brownish yellow, abdomen above more white; beneath the body is paler ochreous-yellow; palpi, forehead and hips blackish. Forewings narrow, with a rectangular apex; white, with a pale ochreous-yellow tinge, in the inner-marginal area brownish. Beneath the ♂ forewing shows short hair in the whole lower half of the cell and between the median veins and lower radial veins. The costa of the hindwing is provided with hair growing longer distally; the colour is on both sides a very pale yellowish white. Expanse of wings: 33 mm. Colombia.

A. trichosema Dogn. (37 d) is similar, larger, the hairy spot of the forewing beneath is much shorter *trichosema*. and situate only below the cell near its end, between the median veins and radial veins. The forewings are silvery white with a brownish proximal margin, only the hindwings yellowish. Expanse of wings: 44 mm. Colombia.

A. rotunda Hmps. (37 d) is easily recognizable by very narrow forewings and almost 3 times as *rotunda*. large round hindwings. Head and thorax brownish-grey, neck and antennae ochreous-yellow, so is the abdomen. Forewings silvery white, in the inner-marginal half purple blackish, also the cell-spaces above it towards the margin, as far as the middle radial. Beneath the ♂ shows very long hair on the forewing in the cell and behind it. Hindwings white, tinted ochreous-yellow. Expanse of wings: 46 mm. Colombia, Bolivia.

A. pseudobisecta Rothsch. (37 d), described according to a ♀, is reddish-brown on its head and thorax, *pseudobi-* the base of the collar orange; abdomen light orange, above brownish. Forewings lustrous light yellow, the proxi- *secta*. mal margin reddish-brown as far as the submedian fold, and forming a projection to the rise of the lower median vein. Hindwings yellowish-white. Expanse of wings: 44 mm. Colombia.

A. meteura Hmps. (36 k) in the ♂ is distinguished by a slight concavity of the distal half of the *meteura*. proximal margin of the forewing which is beneath covered with erect hair. Hindwings very broad. Head and thorax are yellowish-white, tinged brownish, the abdomen of a purer white. Forewings yellowish-white, strewn with reddish-brown scales, which are behind the cell condensed to an oblique shade from the costal margin to the middle radial vein at the margin. Proximal margin of a deeper brownish colour. Hindwings yellowish-white. The ♀ is less densely dusted brown, and the abdomen likewise tinged brown. Expanse of wings: 38 mm. Colombia.

A. brunneostriata Hmps. (37 c). Head and thorax reddish ochreous-brown, abdomen yellowish-white. *brunneo-* Forewings ochreous-yellowish white, in the proximal half with dusted red-brown stripes in the cell-spaces, *striata*. also in the cell-end, below the costa and at the apex brownish spots. Hindwings white, tinged somewhat brown, towards the margin more intensely so. Beneath the costal half is dusted brown. Expanse of wings: 44 mm. South East Peru.

A. nubens Schs. (37 d) has, like the preceding, no hair on the wings. The ♂ shows 4 or 5 bent *nubens*. spines on the basal part of the antennae, on the abdomen lateral long hair-tufts. Head and thorax smoky grey, antennae orange, like the anterior chest, hips and abdomen. Forewings silvery white, at the inner-marginal part smoky grey with a yellow costa. Hindwings white, proximally yellowish, at the margin more or less tinged grey. The ♀ has white anterior chest and hips, the abdomen being also white with a very faint yellowish tinge, also the costal margin white. Expanse of wings: 38 to 42 mm. Mexico.

A. involuta Hmps. (= *albotestacea* Rothsch.) (36 l) greatly resembles *nubens*; the ♂, however, is *involuta*. without the spines on the antennae, the costal margin of the forewing being turned over and roughly scaled, the hindwing beneath showing a large, reddish-yellow scent-scale spot below and behind the cell. Abdomen brownish-grey, with brown anal tufts; costa of the forewing in the middle ochreous-yellow, towards the base blackish. Expanse of wings: 36 mm. Brazil: Castro (Paraná).

A. revoluta Dogn. (36 l) has, like the preceding, an inverted and roughly scaled costal margin, *revoluta*. but the androconium is entirely absent. Head and thorax blackishbrown mixed with grey; chest and legs ochreous-yellow. Abdomen blackish brown, beneath white. Forewing silvery white, at the proximal margin tinged brown, the costal margin orange-yellow; hindwing white, in the costal half yellowish. Expanse of wings: 30 mm. Colombia.

A. submacula Schs. (37 f). Head and thorax dark grey, abdomen light grey; shoulder-covers outside *submacula*. and at the apex white. Forewing silvery white, the inner-marginal area brownish-grey. Hindwing white, at the anal angle dusted grey. Forewing beneath white, with a grey inner-marginal area and a large, greyish-brown postmedian spot, also the margin being greyish-brown. Expanse of wings: 37 mm. Costa Rica.

A. marginata Drc. Beginning from this species, the ♂♂ are without any secondary sexual marks except *marginata*. the anal tufts. Body purple-blackish, palpi yellowish, forehead and antennae whitish; anal tufts black. Forewings white, at the costal margin tinted yellow, the inner-marginal area purple-blackish; beneath with an ochreous-yellow spot in the middle of the costal margin. Hindwings white. In the ♀ the under surface of the forewing and the costal part of the hindwing are brownish-grey. Expanse of wings: 26 to 34 mm. Mexico, Guatemala, Costa Rica.

A. barbipalpia Schs. (37 e) is distinguished by the palpi being covered with long hair turned downward. *barbipal-* Head and thorax brownish-grey and white. Abdomen above dirty white, beneath ochreous-yellow, anal tufts *pia*. brownish-grey. Forewings silvery white, tinted ochreous-yellow; costa ochreous-yellow, towards the base blackish; inner-marginal area purple-grey. Hindwings dirty white. Under surface of forewing ochreous-yellow, towards the margin tinged grey. Hindwing tinted yellow at the costal and distal margins. Expanse of wings: 36 mm. Brazil.

- hampsoni*. **A. hampsoni** Dogn. (37 e). Palpi, like in the preceding, hairy. Head and thorax steel-grey, forehead more brownish; antennae and anterior border of the collar yellow; abdomen above light grey, beneath yellow; legs yellow, at the tarsi blackened. Forewing white, in the proximal half steel-grey, the costal margin fine yellow. Hindwing entirely white. The under surface of the forewing in the ♂ blackish-brown with a broad yellow costa, hindwing white, in the costal part brownish. In the ♀ the underside is unicolorously greyish-white without the yellow costal part. Expanse of wings: 36 to 40 mm. South East Peru.
- erigone*. **A. erigone** Schs. (37 c) differs from *hampsoni* by its longer size, the abdomen being beneath light grey, not yellow. In the ♂ there is, besides, the underside of the forewing lighter grey, along the costal margin, at the cell-end and below the cell reddish-yellow, whilst in the larger ♀ these parts are white. Expanse of wings: 40 to 44 mm. Costa Rica.
- asra*. **A. asra** Schs. (37 f) differs from *erigone* by its much smaller size, the forewings being grey; instead of white, with broadly white veins and a darker grey inner-marginal area. Hindwing likewise grey, at the base and proximal margin white, with a black spot at the costal base. Beneath similar to *hampsoni*. Expanse of wings: 20 mm. Costa Rica.
- tobera*. **A. tobera** Dogn. (37 e) is easily recognizable by the collar being orange-yellow in the anterior half. Head and thorax otherwise brownish-grey. Antennae, chest, legs, and palpi orange, the latter with a black terminal joint. Abdomen orange, towards the base brownish. Forewings silvery white, costa orange, inner-marginal area brownish-grey, beneath tinted orange with a brownish-grey marginal area. Hindwings white. The ♀ is without any orange. Expanse of wings: 38 mm. Ecuador, Bolivia.
- maasseni*. **A. maasseni** Dogn. (= *argentea* Maass., *umbrifera* Drc.) (37 e) is much larger than *tobera*. Body white, tinted brownish-grey, palpi and forehead darker. Anal tuft yellowish. Forewings yellowish-white, inner-marginal area light brownish-grey; beneath orange-yellow, at the margin greyish brown. Hindwings white. In the ♀ the abdomen is darker and beneath the orange colouring is absent. Expanse of wings: 44 mm. Panama, Colombia, Venezuela, Ecuador.
- endoloba*. **A. endoloba** Hmps. (37 e) is distinguished by the very convex, almost lobular proximal margin. Body white, tinted smoky grey, abdomen somewhat lighter; antennae reddish-yellow; underside yellowish. Forewing white, in the proximal half smoky-grey, the costal margin reddish-yellow. Hindwings white. Under surface of the forewing yellowish-white with a large smoky-brown spot at the proximal angle. Expanse of wings: 34 mm. West Colombia (Rio Dagua).
- dognini*. **A. dognini** Hmps. (37 e). Head and thorax smoky-grey, antennae orange; abdomen yellowish-white, above grey with very long anal tufts. Forewings white, in the inner-marginal area grey, the costal margin ochreous-yellow, towards the base blackish. Hindwings yellowish-white, with a strongly extended apex and below it a concave excision. Forewings beneath yellowish, more or less dusted grey, in the ♀ also the hindwings white. Expanse of wings: 48 mm. Bolivia.
- subvoluta*. **A. subvoluta** Schs. (37 f) is very closely allied to *dognini*, but much smaller. The body is above more unicolorously grey. The grey inner-marginal area is below the submedian much darker than above it; at the base of the fringes there is a dark grey line. Hindwings white, at the margin, particularly at the apex tinged grey. Forewings beneath dark grey; hindwings like above, at the apex darker grey. Expanse of wings: 30 mm. French and Dutch Guiana.
- sanctaejohannis*. **A. sanctaejohannis** Schs. (37 f). Body above grey. Abdomen at the end darker. Forewings white, the extreme proximal margin grey. Hindwings white, thickly dusted grey, particularly at the margin. A very small species of an expanse of wings of only 19 mm. French Guiana.
- subcinerea*. **A. subcinerea** Schs. (37 f) is allied to the preceding, but larger. Head and thorax brownish-grey with whitish hair on the basal joint of the antennae; abdomen above dark grey, at the base and end lighter. Forewings white; costa in the ♂ in the basal third finely dark grey, behind it reddish-yellow; proximal margin below the fold dark grey. Hindwings grey, at the base and proximal margin white. Under surface of forewings dark grey. In the ♀ the costa is white, and on the white hindwing only the apex shows a grey tinge. Expanse of wings: 27 to 28 mm. Costa Rica.
- poasia*. **A. poasia** Schs. (37 f) is allied to the following species, but larger. Head and thorax smoky-grey, shoulder-covers with white apices; abdomen dark grey, at the base lighter, at the end brownish. Forewing silvery white, with a smoky-grey proximal margin. Hindwing white, tinged yellowish. Forewings beneath smoky grey, with a white subcostal stripe and a white proximal margin. Hindwings white. The ♀ has more purely white hindwings, and a lighter under surface of the forewings. Expanse of wings: 38 to 36 mm. Costa Rica.
- sericea*. **A. sericea** Drc. (= *galactina* Maass., *limpida* Mschlr.) (37 f) is a very common and widely distributed species, from Mexico through the whole of Central America, Brazil, Colombia, as far as Bolivia and Peru. The ♂ is above white, on the body slightly tinged brownish-grey, with yellowish anal tufts; forewing with a narrowly blackish-grey costal margin and a slightly darker inner-marginal area, which is still darker in the ♀. The abdomen is white in the ♀. — In Brazil and Bolivia there flies a form: **petrola** Schs. with a darker grey thorax and proximal margin of the forewing. Expanse of wings: 30 to 34 mm.
- endocapnia*. **A. endocapnia** Hmps. (37 f). Head and thorax blackish-brown, antennae brown; abdomen white, above brownish. Forewings silvery white, at the proximal margin tinged deep blackish-brown. Hindwings white, under surface white, forewing in the marginal area brownish. Expanse of wings: ♂ 38 mm, ♀ 40 mm. Peru.

A. phaeopasta Dogn. (37 h). Smaller than the preceding, and with more pearl-coloured forewings; *phaeopasta*. hindwings white, the margin finely blackish towards the apex. Forewings beneath brownish-grey, so are the hindwings, though with a whitish costal part. Antennae yellowish. Expanse of wings: 25 mm. South East Peru.

A. auraria Dogn. (= *rubrofasciata* Rothsch.) (37 g). This species and the 2 following ones are distinguished *auraria*. by red stripes on the submedian fold of the forewing; the present species differs from the following by the slate-grey colour of the proximal margin being extended also across the brick-red stripe up to the cell. The rest of the forewing ochreous-yellow, the hindwing lighter. Anterior body slate-coloured, on palpi, forehead, collar, and shoulder-covers spotted brick-red; the under surface and the abdomen ochreous-yellow. Expanse of wings: 50 mm. Ecuador. — In **fuscifusa** nom. nov. (= ab. 1 *Hmps.*) from Bolivia the abdomen and the proximal margin *fuscifusa*. of the hindwing are suffused with a brownish-black colour.

A. umbrifera Fldr. (37 g) differs from *auraria* by the slate-colour of the proximal margin of the fore- *umbrifera*. wing being only visible below the orange-red submedian stripe; forewings otherwise light orange-yellow, hindwings somewhat lighter. Anterior body slate-grey, spotted orange-yellow; abdomen orange. Expanse of wings: 42 to 54 mm. Known from Colombia, Venezuela and Bolivia.

A. sanguivitta *Hmps.* (37 g) is recognizable by the silvery white forewings with a purple-blackish *sanguivitta*. proximal half and a hemochrome stripe above the submedian fold; the costa is orange-red. Hindwings semi-diaphanous white. Anterior body blackish-brown, spotted hemochrome, abdomen ochreous-yellow, above tinged grey. Expanse of wings: 42 to 46 mm. South East Peru.

A. hermanilla Dogn. (37 g) is ochreous-yellow; palpal terminal joint, vertex and thorax dark slate- *hermanilla*. coloured; collar and shoulder-covers distally brick-red. On the forewing the inner-marginal half as far as the submedian fold slate-grey. Expanse of wings: 38 mm. Ecuador (Loja).

A. flavitincta Dogn. (37 g) is a quite monotonously light ochreous-yellow insect, only the inner-marginal *flavitincta*. half of the forewing is purple-blackish. Expanse of wings: 42 mm. Ecuador (Loja).

A. ochritincta Dogn. (37 g) has a yellowish head with orange antennae; palpi with hair turned *ochritincta*. downward; thorax reddish-brown, abdomen ochreous-yellow, above whitish. Forewings ochreous-yellow, in the marginal area chalky white, at the proximal margin brownish. Hindwings yellowish-white. Expanse of wings: 42 mm. Colombia.

A. strigula *Hmps.* (37 g) has a blackish-brown forewing with an orange stripe at the costa, median and *strigula*. base of the submedian; hindwings orange-yellow, dusted brownish, in the ♀ more purely yellow. Anterior body brownish-black with a blue lustre; palpi, collar, hips and abdomen orange. Expanse of wings: 50 mm. Bolivia.

A. normalis Dogn. (37 h). Head white with orange-yellow antennae and blackish-brown palpi; thorax *normalis*. light reddish-brown, abdomen brownish-yellow. Hindwing silvery white, tinged brownish, at the proximal margin deeper reddish-brown. Hindwings white, faintly tinted yellowish. Expanse of wings: 32 mm. Colombia.

A. idolon Dyar (36 m) is dull ochreous-yellow on its head and collar, the thorax, abdomen and wings *idolon*. white. The under surface of the forewing is grey. Expanse of wings: 27 to 30 mm. Mexico.

A. brunneipennis Dogn. (37 h) is a unicolorously red-brownish animal, only the hindwings are white, *brunneipennis*. with a faint yellow tinge. Expanse of wings: 38 mm. Colombia.

A. abrosa Schs. (37 h). Anterior body and abdomen above light brownish-grey, forehead darker; *abrosa*. venter white like the abdominal sides. Forewings silky lustrous white with a narrow light brownish-grey proximal margin. Hindwings white, rather broad, the margin from the apex to the upper median vein cut off, farther below rounded off. Forewings beneath thickly dusted brown, with a reddish white inner-marginal area. Costa of the hindwing dusted brown. Expanse of wings: 33 mm. Costa Rica.

A. nigritia Dogn. (37 h) is distinguished by long, narrow, blackish-grey forewings, in the inner-marginal *nigritia*. area still more darkened; costal margin somewhat lighter. Hindwings in the disc semi-diaphanous white, distally blackened. Body likewise blackish-grey, antennae ochreous-yellow. Expanse of wings: 34 mm. Colombia (Quindiu).

A. separata Schs. (= *umbrifera* Drc. nec Fldr.) (37 i) has in the ♂ uncommonly large, developed *separata*. valves without any lateral hair-tufts. Thorax blackish-brown, forehead black, vertex, collar, shoulder-covers, abdomen and underside orange, forewing silvery white with a narrow, blackish-brown inner-marginal area, only up to the inner-marginal vein, above it tinted somewhat orange, like the costal margin. Hindwings yellowish-white with a dark apical spot. The ♀ is without the orange colouring of the wings and the dark apical spot of the hindwing. Expanse of wings: 34 mm. Distributed from Panama through Brazil as far as Bolivia. FASSL found the ♂ in copula with *D. laudamia*-♀.

A. ampla spec. nov. (37 i) is allied to the two following species by the reverted appendage of the *ampla*. inner-marginal stripe, which, however, is less developed. Forewing with a yellow costa; hindwing ochreous-yellowish. Forewing beneath brownish-grey. Described according to 2 ♂♂ from Bolivia (Cuesta of Cillutincara) from the Coll. FASSL.

A. dentifera *Hmps.* (37 h). Head and thorax dark brown; palpal base, abdomen and underside orange. *dentifera*. Forewing silvery white with an orange costal margin; inner-marginal area purple-brown, in the middle with a reverted continuation as far as the cell. Hindwings yellowish-white. Expanse of wings: 36 mm. Ecuador.

A. obliquisigna Schs. (37 h) has a broader shape of wings than the preceding, similarly marked, though *obliquisigna*. light ochreous forewings, with a much narrower and longer, reverted spot beyond the middle of the proximal margin as far as the cell. Inner-marginal area and thorax are of a lighter reddish-brown. Expanse of wings: 34 mm. Colombia.

- steniptera*. **A. steniptera** Hmps. (37 i). Forewings very narrow, silvery white with a blackish-brown inner-marginal band, above it tinted ochreous-yellow. Costa ochreous, towards the base blackened. Hindwings yellowish-white, towards the margin darkened. Forewing beneath yellowish, at the margin darkened, with a tooth projecting into the cell. Anterior body blackish-brown, vertex, collar, shoulder-covers and abdomen ochreous-yellow. Expanse of wings: 30 mm. Colombia.
- flavicornis*. **A. flavicornis** Rothsch. (37 i). Head blackish-brown, vertex and antennae orange; collar white, at the apex brownish; thorax above blackish-brown, shoulder-covers orange, at the ends white; abdomen orange-yellow. Forewings silvery white, at the proximal margin with a narrow, blackish-brown, grey-lustrous stripe; costal margin yellow, towards the base brownish. Hindwings white, at the apex tinted brown. Expanse of wings: 32 mm. Peru.
- sordida*. **A. sordida** Rothsch. (37 i) is light reddish-brown on its head and thorax, on the abdomen yellowish-white. Forewings yellowish-white, at the proximal margin brownish with a faded, blackish-brown oblique shade along the lower median vein. Hindwings white. The ♀ is scantily strewn with red-brown scales and without the oblique shade. Expanse of wings: ♂ 36 mm, ♀ 38 mm. Colombia.
- tolteca*. **A. tolteca** Schs. (36 l). Body brownish-grey; palpal base, antennae, legs and anal tuft ochreous-yellow. Forewings silvery-white with a brownish-grey, darkened inner-marginal area and a yellowish costal margin. Hindwings dull ochreous-yellow. Under surface of forewings blackish-grey with a large, yellowish postmedian spot. Expanse of wings: 34 mm. Mexico, Brazil.
- corcovada*. **A. corcovada** Schs. (= *postimparilis* Rothsch.) is much smaller than the preceding, otherwise somewhat similar, but the abdomen is whitish and the proximal margin of the forewing blackish-brownish, in the basal half quite black. On the under surface yellow dusting extends close to the apex. Expanse of wings: 26 mm. From Brazil and Bolivia.
- umbrosa*. **A. umbrosa** Dogn. Head and thorax blackish-brown; palpi, legs and abdomen ochreous-yellow, the latter above darkened; forewings ochreous-yellow with a blackish-brown inner-marginal half. Hindwings lighter. Expanse of wings: 32 mm. Ecuador (Loja).
- ochrota*. **A. ochrota** Dogn. (36 l) is a very small species, on the body and wings light ochreous-yellow, the proximal margin of the forewing of a somewhat deeper yellow. Hindwings somewhat lighter, with a faint grey tinge. Forewings beneath tinted more grey. Expanse of wings: 22 mm. Colombia (2000 m).
- venosa*. **A. venosa** Schs. (37 i). Easily recognizable by the grey forewings striped white on the veins; the costal margin is blackish. Hindwings white, with a darkened costal area. The body is grey with a white spot on the metathorax; palpi, forehead, base of antennae, and hips are orange. Expanse of wings: 32 mm. Brazil.
- crassa*. **A. crassa** Dogn. (37 i). The apex of the forewing is similarly cut off in a right angle as in *marcata* (37 a), but the venation is quite different, the two lowest subcostal veins of the forewing rising petioled from the third, in the ♂ the upper radial vein comes from the middle, in the ♀ from the apex of the accessory cell. Body greyish-black, long-haired, abdomen with more ochreous-yellow hair; palpi black. Forewings lustrous silvery white, with a broad blackish inner-marginal area; costa ochreous-yellow, towards the base black. Hindwings white. On the under surface the forewings are grey with a yellow costal area. The ♀ is of a somewhat lighter colouring. Expanse of wings: 35 to 38 mm. Colombia (Quindiu, at an altitude of 3800 m).

87. Genus: **Neagylla** Hmps.

Separated from the preceding genus by the absence of the accessory cell; on the forewing the two lowest subcostal veins rise, like in *A. crassa*, on a footstalk, from the latter the 3rd and 4th also rise petioled, the uppermost rising freely from the cell; the transverse vein is very strongly curved, above its lower angle the middle radial rises. On the under surface the ♂ shows in and behind the cell-end thick woolly hairing, at the proximal margin long hair being turned upward. Hindwings very broad; the two lower radial veins are on one footstalk with the upper median vein. The palpi exhibit hair which is turned downward; the anterior tibiae and femora show thick hair-tufts, the roughly haired abdomen long lateral anal tufts. Only 1 species:

- nevosa*. **N. nevosa** Dogn. (36 m) is a silvery white species well characterized by the peculiar shape of the wings. Head and thorax are tinted blackish-brownish; the hair-tufts on the legs and the hairing of the abdomen are yellow in the ♂, like the costa of the forewing, white in the ♀. Costal area of the hindwing in the ♂ tinted blackish-brownish. Expanse of wings: 40 to 46 mm. Ecuador (Loja).

88. Genus: **Paragylla** Hmps.

Very closely allied to the preceding, but with much narrower forewings and still larger hindwings. Veins of the forewings and hairy spots like in *Neagylla*. On the hindwing the upper median vein rises before the cell-angle, the two lower radial veins petioled, the upper one with the subcostal vein unpetioled from the upper cell-angle. The palpi are not bearded, the anterior legs without any hair-tufts. The two species known of this genus are:

- amourel*. **P. amourel** Dogn. (36 m), a unicolorously orange-yellow insect with somewhat lighter hindwings. Expanse of wings: 44 mm. Ecuador.
- endophaea*. **P. endophaea** Dogn. (37 m) has whitish forewings, tinged grey in the cell-spaces; the inner-marginal area darker; costal margin towards the base blackish. Hindwing in the costal and marginal areas darkened.

The body is tinged whitish-grey and in the ♂ beneath and on the last ring also above reddish-yellow. In the ♂ the wings are of a pure white, only the proximal-marginal part being blackish-grey. Expanse of wings: 34 mm. Ecuador.

89. Genus: **Nephelosia** Hmps.

Proboscis fully developed; the short palpi are straightly porrect; forehead rounded. Forewing narrow with a rounded costa and oblique margin; the upper median vein and the two lower, long-petioled radial veins rise from the lower cell-angle; the upper radial vein on a common footstalk with the 3 lower subcostals; the 1st subcostal vein anastomoses with the costal. On the hindwing the upper median and lower radial vein are on a very long footstalk, the middle radial being absent, the upper one anastomosing with the subcostal vein. The costal vein rises pretty close to the cell-angle. The genus contains only 1 species:

N. caecina Drc. (36 g). Head and thorax blackish-brownish, mixed with grey. Abdomen blackish-brown with a yellow anal tuft. Forewing whitish, in the basal half tinged brownish and strewn with black; in the inner-angular area there is a large, blackish spot. Hindwings blackish-brown. Expanse of wings: 20 mm. Guatemala. *caecina*.

90. Genus: **Areva** Wkr.

Separated from the preceding genus by the upper median, resp. upper radial veins of the forewing rising below the corresponding cell-angles; the transverse vein runs very obliquely. On the hindwing the upper median and lower radial vein are on a shorter footstalk, the middle one being absent, and the upper one petioled with the subcostal vein. 4 species are known of this genus:

A. laticilia Wkr. (= *jubata* Fldr.) (37 k) is distinguished from the other species by long hair in *laticilia*. the lower cell-half of the forewings beneath; the costal margin of the hindwing is lobularly convex and covers these hair. The transverse vein of the forewing runs so obliquely that it appears in one line with the median. The forewings are white with a darker, brownish-grey inner-marginal half and a brown costa; hindwings tinted yellow, with a brownish margin. In the ♀ the proximal margin is brown only as far as the submedian fold. Expanse of wings: 40 mm. Venezuela.

A. subfulgens Schs. (37 k). Vertex and thorax yellowish-white, the rest of the body brownish-grey. *subfulgens*. Forewing blackish-brown, with a coppery lustre, with a yellowish-white inner-marginal stripe, median and marginal bands. Hindwing brownish-grey, in the basal and inner-marginal half whitish. Expanse of wings: 30 mm. Brazil.

A. trigemmis Hbn. (= *ziza* Drc.) (37 k) has a darker blackish-brown body with whitish spots on *trigemmis*. its collar, shoulder-covers and mesothorax. Forewings blackish-brown with a purple and coppery lustre; small whitish spots at the base of the proximal margin, below the middle of the costal margin, above the submedian fold and below it near the proximal angle, and in the middle of the margin. Hindwings blackish-brown, towards the base whitish. Expanse of wings: 32 mm. Known from Mexico, Brazil and Hayti.

A. albogrisea Roths. (37 k) differs from the preceding by much lighter markings. On the purple- *albogrisea*. brownish forewings are whitish: the base of the proximal margin, a costal-marginal spot above the cell-end, a band behind the cell, and a longitudinal diffuse patch on the upper radial, a band from the cell-end to the proximal margin, and a longitudinal diffuse patch towards the proximal angle; besides there are small whitish spots close in front of the margin. Hindwings light brown, towards the base whitish. The body is light brown, collar and shoulder-covers white. Expanse of wings: 30 mm. Ecuador.

91. Genus: **Metareva** Hmps.

A large accessory cell of the forewing separates this genus from the preceding; the upper median vein is removed to the lower cell-angle. Hindwings like in *Areva*.

M. aenescens Hmps. greatly resembles *A. trigemmis* (37 k), but it is bigger with larger, more clearly *aenescens*. white spots. Head and shoulder-covers with a blue lustre. Expanse of wings: 40 mm. Bolivia.

M. flavescens Dogn. (= *semidivisa* Roths. (37 k). Body yellow, on the vertex, thorax and shoulder- *flavescens*. covers tinted lilac-grey; wings above and beneath straw-coloured, the forewing at the costa finely bordered with yellow, and along the proximal margin with a broad, lilac-grey band. Expanse of wings: 37 mm. Tucuman (Argentina). — **albescens** Dogn. (37 k) from the same habitat is the ♀ of it and differs by all the straw-coloured *albescens*. parts in the ♂ being silvery white here; only the antennae, palpi, forehead and collar above are yellow. Expanse of wings: 39 mm.

M. endoscota Hmps. differs, according to the description, only by its smaller size and the absence *endoscota*. of the yellow of *albescens*: head and thorax white, tinted blackish-brown; abdomen white. Forewings silvery white with a blackish-brown inner-marginal stripe. Hindwings purely white. Expanse of wings: 34 mm. South East Peru.

92. Genus: **Procrimima** Hmps.

On the narrow forewing the upper median vein rises before the cell-angle, the 1st radial vein from the upper angle, the 3rd subcostal vein being absent, the 1st subcostal vein anastomosing with the costal. On the

hindwing the upper median vein anastomoses with the lower radial in the ♂, while in the ♀ they are petioled. All the rest like in the preceding genus. 2 tropical species:

procris. **P. procris** *Fldr.* (36 d). Head, thorax and forewings metallic bluish-green; all the rest blackish-brown in the ♀, in the ♂ with a purple blue, on the ventral side green reflection; the hindwings are rather thinly scaled. Expanse of wings: ♂ 24, ♀ 32 mm. Colombia, Peru.

viridis. **P. viridis** *Drc.* Body greenish black, antennae black. Wings above quite black, beneath light metallic bluish-green. Expanse of wings: 29 mm. Brazil.

93. Genus: **Ardonissa** *Dogn.*

Proboscis well developed; the erect, long-haired palpi project beyond the head; ♂ antennae ciliated, not thickened; forewings rather long and narrow; the upper median vein comes from the lower cell-angle, from which also the two lower radial veins rise petioled; the upper one comes from below the angle; the uppermost subcostal vein does not anastomose with the costal. Hindwings similar as in the following, but the upper median vein is petioled with the lower radial. Based upon 1 species from a lofty habitat in Peru.

adscitina. **A. adscitina** *Dogn.* (36 d). Body black with a dull bluish-green reflection. Forewings above metallic bluish-green, at the base brighter green, peacock-blue or coppery-bronze in a variable extent, sometimes also in the shape of stripes as far as the margin. Hindwings bluish-black. Expanse of wings: 23 to 24 mm. Peru (Cuzco).

94. Genus: **Ardonea** *Wkr.*

Separated from the preceding genus by shorter, roughly haired palpi not reaching the vertex, and the antennal shaft being thickened before the middle, in the ♂ doubly combed, in the ♀ set with ciliary bristles. On the forewing the lower median vein rises behind the middle, the upper one before the lower cell-angle, from which the two lower radial veins rise unpetioled; the upper radial comes from the cell-angle; the 3 lowest subcostal veins rise on a joint footstalk, the 2nd freely from the cell, the uppermost anastomoses with the costal. On the hindwing the upper median and the lower radial vein come from the lower cell-angle; the middle radial is absent, the upper one on a short footstalk with the subcostal. The genus contains 5 forms from the northern parts of South America.

tenebrosa. **A. tenebrosa** *Wkr.* (36 d) is a very peculiar animal. The ♂ has the antennae above provided with thick hair, the abdomen is roughly haired, and the anal angle of the hindwing extended to a long lobe. Forewings yellowish-white, with blackish-brown veins, and in the marginal area internerval stripes, blackish-brown spots near the base, behind the cell, towards the proximal angle, at the apex and at the margin; hindwings diaphanous brownish-white, at the costal margin and apex more darkened. Collar and shoulder-covers spotted yellowish-white, anal tuft orange to carmine. In the ♀ the dark colour is much more extensive. Metathorax with an orange spot. — In the form **peculiaris** *Drc.* the hindwings are much more darkened. Expanse of wings: 32 mm. Peru, Colombia.

nigella. **A. nigella** *Dogn.* (36 d) is a minute, dark brown insect with a coppery-purple reflection; the hindwing is but slightly produced at the anal angle, the antennae only ciliated. The ♂ exhibits on the sides of the 5th abdominal ring long red-brown hair-tufts. Expanse of wings: 20 mm. Ecuador.

morio. **A. morio** *Wkr.* (= *coracina* *Bsd.*, *unicolor* *Fldr.*) (36 d) is an extremely common animal of a very vast range. Body and forewings are of a deep bluish-green, hindwings of a purer blue. Expanse of wings: ♂ 34 mm, ♀ 40 mm. From Mexico through the whole of Central America as far as Colombia and Venezuela.

judaphila. **A. judaphila** *Schs.* (36 h) is a very small species of an expanse of only 21 mm. Head dark brown; collar and thorax orange-red. Abdomen violettish-black. Forewings greyish-brown; costal and proximal margins shaded with violet, similar internerval stripes are in the marginal area; at the base an orange-red patch. Hindwings brownish-grey. From French Guiana.

95. Genus: **Apistosia** *Hbn.*

Very closely allied to the preceding genus and differing in the veins almost only by the presence of an accessory cell; the uppermost subcostal vein terminates freely into the costal margin and does not anastomose with the costal. The antennae are not thickened in the middle, in the ♂ combed or ciliated. The 1st abdominal ring shows strong, lateral tubercles. This genus belongs to the few *Lithosiinae*-genera that are represented on the eastern and western hemispheres. *Comp. Vol. II, p. 63, and Vol. X, p. 198.*

judas. **A. judas** *Hbn.* (36 e) is orange on its head and thorax; palpi, antennae, legs, and abdomen are brown with a blue reflection. Forewings dull bronze-green with a feeble brownish coppery lustre, in the marginal area more bluish. Hindwings brown. In the ♀ the abdomen shows orange sublateral spots on the last ring. Expanse of wings: ♂ 46, ♀ 56 mm. Known from Mexico, Guatemala, Honduras, Nicaragua, and Panama.

A. phaeoleuca Dogn. (36 e) looks like an *Agylla*: white with a brownish-grey inner-marginal stripe *phaeoleuca*. on the forewing; similar internerval stripes are in the cell and marginal area. Beneath in the lower half of the cell of the forewing covered with hair. Expanse of wings: 38 mm. Ecuador.

A. pogonoprocta Dogn. (36 e) greatly resembles the preceding and differs above all by the absence of *pogono-* the hair on the under surface of the forewings, as well as by the ochreous-yellow costal margin and long, yellowish *procta*. hair-tufts on the abdominal end of the ♂. The ♀ is of a much purer white, only the proximal margin of the forewing is brownish-grey. Ecuador (Loja).

A. humeralis Grt. (36 e) greatly resembles *judas* (36 e), but it has only ciliated antennae in the ♂. *humeralis*. Head and thorax are orange, like the anterior and middle hips and femora, as well as the anal tuft. Shoulder-covers, legs and abdomen are of a brighter metallic bluish-green than in *judas*, so are the wings, too. The ♀ is without the orange anal tuft, but instead it shows an orange transverse band before the end. Expanse of wings: 38 to 46 mm. Cuba.

96. Genus: **Glaucosia** Hmps.

Proboscis developed; the short, porrect palpi do not project beyond the forehead. ♂ antennae with ciliary bristles; tibiae with short spurs; abdomen roughly haired. On the forewing the two lower radial veins rise separately, the upper one from below the upper cell-angle; the 2 lowest and the 2 middle subcostal veins are each on a separate footstalk, only the uppermost being free. On the hindwing the upper median vein comes out before the cell-angle; the two lower radial veins are petioled, so is the upper one with the subcostal vein. The proximal angle is long-haired.

G. agyllia Hmps. (36 e) is a minute insect resembling an *Agylla*, with greyish-white forewings, dusted *agyllia*. brown on the proximal margin. Hindwings brownish-grey, like the head and thorax, whilst the abdomen is blackish-brown; chest and legs whitish. Expanse of wings: 24 mm. Brazil (Espiritu Santo).

97. Genus: **Parapalosia** Dyar.

Differs from the preceding by 2 pair of long spurs on the posterior tibiae, by the presence of an accessory cell on the forewing, on which the uppermost subcostal vein anastomoses with the costal. All the rest as in *Glaucosia*. Likewise only 1 very small species, with much shorter and broader forewings than in *Glaucosia*, shaped like a small European *Lithosia*.

P. cinderella Schs. (36 e). Head and thorax reddish yellowish-grey; abdomen grey, towards the end *cinderella*. darker. Forewings light grey, with a very broad, darker grey transverse shade from near the base to the cell-end. Hindwing whitish, towards the margin tinged grey. Expanse of wings: 19 mm. The tiny, insignificant animal was described from French Guiana.

98. Genus: **Euryptidia** Hmps.

Of this genus 4 black and yellow species are known, closely approximating the *Josiodes* (35 d—f) in their habitus and colouring. Proboscis developed. The erect palpi do not reach the vertex and are below long-haired on the basal joint. Posterior tibiae with moderately long spurs. Forewings broad, the venation very much like in *Glaucosia*, but the two uppermost subcostal veins terminate freely from the cell into the costal margin, and the 3 lower ones are on a joint footstalk; no accessory cell. The venation of the hindwing similar, but the two lower radial veins may be petioled or also run separately.

E. univitta Hmps. (36 f) is the only species the ♂ antennae of which are provided with ciliary tufts, *univitta*. almost combed. Body black; forewings orange, costal margin, proximal margin, and inner-marginal vein black, distal margin and apex broader black; hindwings entirely black. — **discalis** *nom. nov.* (= ab. 1 Hmps.) *discalis*. has a black discal spot on the forewing also above, whilst in the typical form it is visible only beneath. Expanse of wings: 46 mm. Distributed from Brazil to Argentina.

E. trifera Wkr. (= *striata* Btlr., *laeticolor* Fldr.) (36 f) has, like the following, simply ciliated *trifera*. antennae. Body and hindwings black. The forewing in the basal half orange with black-striped veins and folds, and an oblique, orange postmedian band. Hindwing beneath with an orange oblique band from the submedian fold to the lower cell-angle. — In (♂) *form. nov. extensa* the orange colour shows through also above *extensa*. and is beneath much more extensive. In the ♀ there is always a broad orange band on the hindwing, extending from the base of the proximal margin to the lower cell-angle and into the cell. Expanse of wings: ♂ 38, ♀ 46 mm. Amazon, Espiritu Santo.

E. basivitta Wkr. (36 f) greatly resembles *univitta*, but it has simply ciliated antennae, and the black *basivitta*. of the inner-marginal vein extends as far as the proximal margin itself, but it ends behind the middle. Expanse of wings: 44 mm. Brazil (Rio de Janeiro). It almost resembles *Josia auriflamma* Hbn. with which it flies in common.

ira. **E. ira** Drc. (36 f) is the smallest species of an expanse of only 26 mm. Body black with a blue reflection; neck and spots on the shoulders orange. Forewing in the basal half orange, at the costal base a black spot. Hindwing with an orange spot at the base from the proximal margin to the costal margin. Mexico.

99. Genus: **Antona** Wkr.

Palpi much longer than in the preceding genus and roughly scaled; abdomen roughly haired. On the forewing the venation is very much like in the preceding; the upper radial vein comes from below the upper cell-angle, and the uppermost subcostal vein anastomoses with the costal. Hindwings likewise similar.

subluna. **A. subluna** Wkr. (36 f) is bluish-black on its body and wings; spots on the shoulders and the margins of the shoulder-covers are scarlet, like a minute spot at the base of the forewing. The hindwings are thinly scaled in and below the cell towards the base, beyond they exhibit a white hyaline spot. In the ♀ the last abdominal ring is beneath spotted red. ♂ antennae combed. — **major** *form. nov.* (= ab. 1 *Hmps.*) is much larger, up to 52 mm, the red spots are larger, on the hindwing the hyaline spot is extended to the base. The type has an expanse of wings of ♂ 40, ♀ 44 mm. Brazil (Rio de Janeiro).

diffinis. **A. diffinis** Wkr. (36 f) has in the ♂ the antennae only with ciliary bristles, and a long-extended and roughly haired anal angle of the hindwing. The body is blackish-brown with a blue reflection, the shoulder-covers and metathorax spotted orange-red. Hindwings semi-diaphanous, with bluish-black hair. Expanse of wings: 32 mm. Known from Trinidad, Brit. Guiana, and Brazil.

100. Genus: **Progona** Berg.

Proboscis stunted, palpi very short; antennae ciliated. Spurs of tibiae very short; abdomen roughly haired. In the venation separated from the preceding genus by the lower radial anastomosing with the upper median vein on both the wings; on the forewing the upper radial vein rises below the upper cell-angle; an accessory cell may be present or absent; on the hindwing the upper radial and the subcostal vein are on a much shorter pedicle. The genus contains few species somewhat resembling our *Lithosia*.

xanthura. **P. xanthura** Schs. (36 g). Body blackish-grey; hindhead, anterior half of the collar, and anal tuft orange. Forewings light greyish-brown with a coppery lustre, with a costal-marginal streak being pointed towards the apex; costa towards the base blackish. Hindwings blackish-grey. Accessory cell absent. Expanse of wings: 22 mm. Brazil, Castro (Paraná).

luridipennis. **P. luridipennis** Burm. is well characterized by the red-brown forewings with whitish veins; hindwings still darker brown. Anterior body whitish, abdomen dark brown. Expanse of wings: 26 mm. Argentina.

sadima. **P. sadima** Schs. (36 g) is larger than the preceding, lighter brownish-grey with a reddish-yellow costal margin, with a whitish streak below it; hindwings yellowish-white, towards the margin and costa blackish. Accessory cell present. Expanse of wings: 26 to 30 mm. Brazil.

pallida. **P. pallida** Mschl. (36 g) is the smallest species, of a very light, reddish-brown colouring with a faded white costal-marginal streak. Hindwings white, at the apex brownish. Expanse of wings: 18 mm. Porto Rico.

101. Genus: **Crambidia** Pack.

Hereto belong a dozen species greatly approximating our *Lithosia* in the habitus and chiefly representing this genus in North America, where the real *Lithosia* are absent. The genus is very closely allied to the preceding and differs only by the lower radial vein of the hindwing being petioled with the upper median vein. An accessory cell of the forewing may be present or absent. They are pale animals with narrow wings, recalling the *Crambus* only by the shape of the wings and the size, but not by the palpi, which are even very short.

pallida. **C. pallida** Pack. (36 h) is quite monotonously greyish-brown with somewhat lighter hindwings. Expanse of wings: 28 mm. United States.

lithosioides. **C. lithosioides** Dyar (36 g) is darker slate-coloured with an anteriorly yellow collar. The forewing exhibits a very narrow, light yellow costal stripe. Hindwings towards the base lighter. Expanse of wings: 21 mm. United States as far as Texas.

uniformis. **C. uniformis** Dyar (36 g) differs from the preceding by the veins being striped dull ochreous-yellow, and is somewhat smaller. United States.

roberto. **C. roberto** Dyar (36 g) has an ochreous-yellow head; thorax and forewings are whitish, the latter with a black costal base. Abdomen and hindwings as well as the under surface blackish-grey; fringes of the hindwings white. Mexico (Tehuacan).

casta. **C. casta** Pack. (= *candida* H. Edw.) (36 g) is a larger species of 26 to 34 mm. Body and wings are white, dusted greyish-brown; base of costal margin on the forewing black. Legs blackish-brown. — In the

form **cephalica** Grt. & Rob. the head and anal tuft are yellow, the hindwing often darkened; it is of late considered *cephalica*. as a distinct species. United States.

C. scoteola Hmps. (36 g) has more ochreous-brownish wings with a whitish costal-marginal streak; *scoteola*. the costa itself is orange-yellow, in the basal third black. Hindwings blackish-brownish, fringes and border in front of them yellow. Expanse of wings: 26 mm. Bolivia, from the Rio Songo.

C. suffusa Bs. & McD. is a larger species, having recently been described as a novelty from California, with white forewings, tinted brownish, with a purely white subcostal stripe; the costal margin is blackened towards the base. Hindwings light brown with white fringes. Head and anal end are light reddish-yellow, anterior body whitish, with a pale brownish tinge, the abdomen more grey. Legs blackish-brown. Expanse of wings: 34 mm.

C. pura Bs. & McD. shows a purely white body, only the ventral side and the legs are anteriorly *pura*. blackened. Forewings silvery white, hindwings likewise white. Expanse of wings: 26 mm. Carolina, Texas.

C. impura Bs. & McD. (= casta, ab. 2 Hmps.) is much larger than the preceding and besides *impura*. different by the hindwings being tinged blackish-brownish, also the head and thorax being slightly brownish. Expanse of wings: 34 mm. Colorado, Arizona.

C. dusca Bs. & McD. has a light grey body, the head being darker grey. Forewings grey, with *dusca*. a slight ochreous-yellowish tinge; by the cell-spaces being striated brownish-black the veins are set off in a lighter shade. Expanse of wings: 26 mm. California.

C. allegheniensis Holl. is slate-coloured on its thorax and abdomen, the head, collar, and shoulder-*allegheni-* covers being light yellow. Forewings likewise slate-coloured with a light yellow costal-marginal streak. Hindwing *ensis*. semi-diaphanous white. Expanse of wings: 30 mm. Pennsylvania.

102. Genus: **Phaeosia** Hmps.

Very closely allied to the preceding genus and chiefly distinguished by the developed proboscis and rounder forehead. The palpi are somewhat longer. In the veins no difference. So far only the typical species is known.

P. lutea Drc. (36 h) is whitish on the body, dusted blackish-brown. Forewings brownish-grey, at *lutea*. the costal margin lighter; the latter exhibits towards the base a black streak. Hindwings darker. Expanse of wings: 26 to 30 mm. Described from Guatemala. — The form: **intermedia** Drc. (36 h) from Mexico is on *intermedia*. the forewings much lighter.

103. Genus: **Agkonina** Dogn.

This genus contains 3 very peculiar species differing very much in the venation and with greatly differentiated secondary sexual marks. Proboscis well developed. Palpi erect, on the 2nd and 3rd joints laterally covered with long hair turned downward, projecting beyond the forehead. Antennae with ciliary bristles. Abdomen roughly haired. On the forewings the lower median vein rises behind the middle of the cell; the middle radial is absent, the upper one is petioled with the subcostal veins, the 3rd and 4th of which anastomose and form the accessory cell; the two uppermost subcostal veins terminate into the costal. The costal margin shows in the ♂ near the base a lobe with a hair-tuft.

A. ovifera Dogn. (36 h) is light ochreous-yellow on its body and wings. Head, thorax, and interior *ovifera*. side of the forehips brownish, posterior tibiae with a black hair-tuft. Forewings similar as in the following species with a V-shaped dark band; costal base brownish. The ♂ exhibits on the median of the forewing an oviform androconium. Expanse of wings: 30 mm. From South East Peru.

A. pega Dogn. (36 h) greatly resembles *ovifera*, but it is somewhat larger, and the androconium *pega*. is situate in the cell of the hindwing beneath, whereby the venation is greatly changed, being crowded together in the costal-marginal half, the larger inner-marginal half being almost void of veins. Expanse of wings: 36 mm. Ecuador (Loja).

A. miranda Hmps. (36 h) is yellowish-white on its body and wings; head and thorax are brownish; *miranda*. a tuft of scales on the posterior tibiae black. The costal lobe of the forewing is black with a round spot of reddish-brown scales in it, connected with a large, blackish-brown inner-angular spot; at the margin and before it there are accumulations of dark scales, forming indistinct transverse bands. The elliptic androconium is placed on the footstalk of the upper radial vein with the subcostal. The shoulder-covers are greatly prolonged by hair-tufts. Expanse of wings: 30 mm. Bolivia (Rio Songo), Peru (Marcapata).

104. Genus: **Disoidemata** Hmps.

Proboscis well developed. Palpi shorter than in the preceding and without hair. Spurs of posterior tibiae longer. Forewings short and broad. The middle radial vein is present, rising with the lower one from the cell-angle. The ♂ exhibits above a round androconium below the middle of the cell, and in the middle of the proximal margin a long tuft of black hair. Cell of the hindwing short; the lower median vein rises from

the middle, the upper one close before the angle; the two lower radial veins and the upper one with the subcostal vein are extremely long-petioled. Costal vein feeble. The distal margin is in the ♂ very concavely excised; above at the cell-end a round scent-spot. The genus only contains two very small species:

osmophora. **D. osmophora** *Hmps.* (36 h). White with ochreous dusting. Costa of the forewing towards the base black; in the basal and marginal areas disperse darker scales and a large, postmedian horseshoe-spot of black colour. Expanse of wings: 18 mm. Mexico (Vera Cruz).

quadriplaga. **D. quadriplaga** *Dogn.* is smaller, the spot of the forewing is distally almost square; besides there are a fine marginal line dotted black and in some places black speckled fringes. Hindwings brown. Expanse of wings: 14 mm. French Guiana.

105. Genus: **Cyclosticta** *Hmps.*

Rather closely allied to the preceding and chiefly distinguished by the non-excised margin of the hindwing in the ♂. On the forewing the two lower radial veins are petioled. The ♂ shows beneath in and below the cell-end a large, reddish-yellow androconium. Veins of the hindwings similar as in *Disoidemata*, but the footstalks of the radial and subcostal veins much shorter. Only 1 species:

discata. **C. discata** *Schs.* (36 h). On body and wings white, dusted yellowish; the costal margin of the forewing ochreous-yellow, proximal margin dusted brownish-grey. Hindwing white with a yellowish-white scale-spot in the cell-end. Expanse of wings: 28 mm. Brazil (Rio de Janeiro).

106. Genus: **Mintopola** *Hmps.*

In the venation different from *Cyclosticta* by the upper radial vein of the forewing rising from below the upper cell-angle. Palpi shorter, more slender; forehead rounder. The ♂ exhibits above in the subcostal space and in the upper half of the cell rows of scent-scales. The roughly haired proximal margin of the hindwing is inverted. Only 1 species:

braziliensis. **M. braziliensis** *Schs.* (36 i). Head and thorax light-brown, abdomen more grey, with a brownish anal tuft. Forewings light brown, in the median area and proximal angle dusted blackish-brown. Hindwings whitish, towards the base brownish. Expanse of wings: 28 mm. Brazil (Petropolis, Rio de Janeiro).

107. Genus: **Disaulota** *Hmps.*

The only species forming this genus derives its name from the resemblance to the Pierid genus *Leptalis*, caused by its white colour as well as by the abnormally large hindwings. Proboscis developed; the erect palpi do not reach the vertex. ♂ antennae ciliated. Forewing short with a curved costal margin, the apex and distal margin uniformly rounded. The venation is very peculiar from the circumstance that, beside the usual accessory cell, another one is effected by the anastomosing of the upper and lower radial vein, in the first third of the two beyond the discocellular; the middle radial is absent. The hindwings are larger and longer than the forewings; the lower radial anastomoses with the upper median vein, the middle one being absent; the upper radial vein and subcostal unpetioled. Costal margin long-haired.

leptalina. **D. leptalina** *Drc.* (36 i) is white, on its head, thorax, as well as the discal area and base of proximal margin of the forewing dusted purple-blackish. Hindwing below the middle of the margin blackish-grey. The ♂ shows beneath in the discal area a very large androconium, the costal margin is beneath hairy. Expanse of wings: 40 mm. Costa Rica.

108. Genus: **Tigrioides** *Btlr.*

Proboscis fully developed; palpi stretched forward. ♂ antennae with ciliary bristles; posterior tibiae with short spurs; abdomen roughly haired. Forewings long and narrow, the costal margin towards the apex curved, with a short distal margin. The lower median vein emerges at the base curved from the middle of the cell, the upper one is on a long footstalk with the lower radial vein; the middle radial is absent, the upper one is petioled with the 3 lower subcostal veins; the first subcostal anastomoses with the costal vein. The lower median vein of the hindwing rises far before the cell-angle, the upper one on a long footstalk with the lower radial vein, the middle radial is absent, the upper one is petioled with the subcostal vein; the costal rises from the middle of the cell.

To this genus being sometimes also denominated *Lexis* belong about 20 species mostly rather similar to our *Lithosia*. In the Old World the genus is widely distributed and particularly numerous in the Malayan Archipelago. In America there is only 1 species looking something like a much-flown *Lithosia deplana* or *cereola*. As to further particulars about the genus see Vol. X, p. 214.

T. bicolor Grt. (= *argillacea* Pack.) (36 i). Body and wings are blackish-brown; collar, anal tuft, *bicolor*. and a costal-marginal streak being pointed towards the apex are yellow. Expanse of wings: 30 mm. Canada; United States, Colorado.

Correction and Additions to the Lithosiinae.

P. 265. In the 47th genus *Ascapesyle* is mentioned once more. This genus is identical with the 31st genus *Ascapesyle* Dyar on p. 254.

P. 272. To the genus *Tuina* Btlr. add yet the following species: **T. maurella** sp. nov. (38 a). Velvety *maurella*. black, collar, abdominal sides, a small basal spot of the forewing, and the basal two thirds of the hindwing are of a deep rosy-red. From Costa Rica (Orosi); 2 specimens from the Coll. A. H. FASSL.

III. Micrarctiinae.

It has already been stated in Vol. II (p. 71), when introducing this name, that this division does not represent the establishing of a systematically definable subfamily, but a heading into which those Arctiid genera are ranged which are not easily inserted in the *Nolinae*, *Lithosiinae*, *Nyctemerinae*, *Hypsinae* etc. The genera united here also exhibit of course great differences, as for instance the single genera of the *Spilosominae*, *Callimorphinae* etc., and beside the *Apantesis* closely allied to our European *Orodemnias* and *Parasemia* there are *Hoplarctia* recalling the palearctic *Ocnogyna*, moreover the *Phragmatobia*, the *Argina* forming the transition to the *Hypsinae*, and others. We place here also those genera forming, so to speak, the point of junction between the *Lithosiinae* and the other Arctiid branches. These are the *Gnophria*, considered by some systematizers as *Lithosiinae*, by others as *Arctiinae*. The *Atolmis*, as this genus is denominated in Vol. X, are still kept separated from the *Gnophria* in KIRBY's Catalogue, to which genus, beside the *Gn. rubricollis* (Vol. II, p. 70), some Americans are yet placed, which we have dealt with as indisputable *Lithosia*, such as *Gnamptonychia flavicollis*, which also greatly approximate the typical *Lithosiinae*-genera, such as the *Macropstila*, *Agylla* and *Ilema* (*Lithosia*). We cannot expect many common features from a group of animals purely formed by exclusion. The deviations from the typical *Arctiinae*, by which its separate position is effected, do not move in the same direction. We observe the *Eubaphe* and *Virbia* forming the transition to the *Lithosiinae*, the *Haploa* to the *Callimorphinae*, the *Argina* to the *Hypsinae*, the *Hoplarctia* to the *Spilosominae*, the *Orodemnias* and *Apantesis* to the genuine *Arctia*. Some forms also recall the *Phaegopterinae*, so that we find resemblances to all the larger groups of *Arctiidae*.

More constant than the imagines are the larvae, in which we do not meet with any deviations as exhibited in the *Spilosominae* by the larva of *Isia isabella* being armed with dorsal brushes, or by the *Phaegopterinae* with even long hair-pencils. Nor do we scarcely find in this group any real tree-larvae, as for instance in the *Hyphantria*, *Aganais* etc.

As to the colouring, a bright red and orange-yellow are the usual colours, being set off by black spotting like in most of the *Arctiidae*. Even in the *Utetheisa*, which in the Old World almost all exhibit a purely white ground-colour, in certain American forms the red colour of the hindwings appears yet distinctly, though in certain local forms it fades in the same way as in the allied *Haploa*, where the orange colour of the hindwings gradually disappears together with the black spotting and the entirely white forms get the upper-hand, so that in most of the *Spilosominae* the whole surface is already white and only the end of the abdomen shows yet some of the warning colour.

We may presume that nearly all the *Micrarctiinae* occur in great numbers of specimens. If, as we see in some *Eubaphe*, *Virbia* or *Apantesis* species, some are more rarely met with in collections, and are more highly estimated on account of their supposed rareness, we may be certain that the reason of this symptom is the inaccessibility of the habitats or the greater capability of hiding. The *Parasemia*, *Leptarctia*, nearly all the more widely distributed forms of the *Apantesis*, the *Phragmatobia* etc. are almost all just as common insects as most of the *Spilosominae* are, the *Callimorphinae*, or even the *Phaegopterinae*, which may sometimes grow extremely troublesome when capturing them by the lamp; and if the food-plants would not be throughout futile weeds, many a larval species of this group would be able to grow as pernicious as the *Spilosomina Hyphantria cunea*.

1. Genus: **Eubaphe** Hbn.

This genus which in conjunction with *Crocota* Hbn., is often mentioned by the more recent name of *Holomelina* H.-Schäff., is composed of about 2 dozen mostly North American species exhibiting yet so many resemblances to the *Lithosiinae* in their shape and habits, that older authors inserted them in the *Lithosiinae*. They are all small butterflies, with greyish-brown forewings, suffused with yellow or reddish, and red or yellow hindwings, mostly margined black. Proboscis absent; the long palpi in the resting imago drooping, somewhat beak-shaped. Head woolly, thorax with appressed scales, abdomen obtuse. In the triangular forewing the subcostal is 4-branched, the first branch forking close before the cell-end, the last close before the apex of the wing. On the hindwing veins 5 and 4 come from the lower cell-angle. Little is known of the larvae; they are reported not to live on lichens, but on low plants, having in their juvenile state a cordiform head; when grown up, they show tubercles haired with short, uniform, stiff bristles, of which only those at the anterior and posterior ends exhibit longer hair-tufts; they hibernates and yield the imagines in June and July in the northern parts of the United States, whilst to the south they seem mostly to have 2 generations (in June and August). In day-time the larvae are met with freely on the soil, the imagines in the grass on pastures or in cleared woods; at night they come to the lamp. In most of the places of the United States there are always only 1 or 2 species, however often in various forms. Most of them occur in Mexico and the Antilles; only few go as far as Central America, and only 1 to Colombia or Peru. Opinions differ greatly as to whether the single forms are entitled to be called species.

- aurantiaca*. **E. aurantiaca** Hbn. (38 b). Forewings brown. Hindwings rosy-red, both slightly tinted yellow. Along the costa of the forewing a red stripe. Eastern United States, to the west as far as the Rocky Mountains and to the south as far as Mexico, to the north as far as Canada; mostly not rare. — On the hindwing there are sometimes faint blackish shades flowing together to a marginal band in the form **brevicornis** Wkr. (= *marginata* Drc., *belfragei* Stretch) (38 b), before which band in the ♀ there is besides a dark discal spot. This form is often considered as a distinct species; it is common in the Gulf States, particularly Louisiana and Texas. —
- brevicornis*. **rubicundaria** Hbn. is almost the same, the marginal band of the hindwing very broad, the hindwings themselves often orange instead of rosy. — **ferruginosa** Wkr. has no black band of the hindwing, but dark spots (mostly 2) before the margin of the hindwing, and the forewings show dark brown transverse shades; it is always larger than *aurantiaca* and, according to ROTHSCILD, a distinct species. — **quinaria** Grt. (= *choriona* Reak.) has on the forewings 4 or 5 creamy-white, small spots, of which in **bimaculata** Sndrs. only 1 is noticeable. — Larva emerging from low, flatly spherical, pale yellow eggs, is light brown, with a black head, black hair and dark tubercles partly with light apices. Across the dorsum a dull orange-coloured dorsal line. Eggs deposited in June yielded the imago in August. Pupa in a light silky web.
- rubicundaria*. **E. diminutiva** Graef. (38 b) is perhaps only a unicolorous pygmean form of *aurantiaca*, according to HOLLAND, however, constant, yellowish-brown, unmarked, the hindwings somewhat redder than the forewings. Florida, very common.
- ferruginosa*. **E. opella**. It occurs in lighter and darker to almost black (**belmaria** Ehrm., 38 a) specimens, and *nigricans* Reak., *nigrifera* Wkr., *obscura* Stretch are only names referring to such entirely or partly darkened specimens.
- quinaria*. Typical **opella** Grt. have reddish-brown forewings and almost black hindwings being reddle-coloured only in the inner-marginal area. — **rubricosta** Ehrm. are specimens being quite black, except the middle of the costa of the hindwing. Rather common in the Eastern United States, to the south as far as Georgia. — Larva when grown up dark grey with black tubercles, a black head and black hair. On low plants, very polyphagous.
- bimaculata*. **E. immaculata** Reak. (38 a) is allied to the light specimens of the preceding species, also similar to typical *aurantiaca*, but larger than the latter; rarely spotted (= **trimaculosa** Reak.), mostly the forewings unicolorously yellowish-brown, hindwings dull vermilion. Texas, Colorado; rarer.
- diminutiva*. **E. intermedia** Graef. (38 b) has brown forewings and purple hindwings, with such a broad black margin that the marginal black takes up two thirds of the whole hindwing. Costa of the forewing usually scarlet. Texas. — **cocciniceps** Schs. from Manitou (Colorado) has a narrower black margin of the hindwing; — **parvula** Neum. & Dyar is coloured like the latter, but smaller, the wings not so pointed. The marginal black of the hindwing occupies $\frac{1}{3}$ of the wing at most. Apparently rarer.
- belmaria*. **E. polyphron** Drc. (38 b). A southern species. Hindwings like those of the preceding species, purple-pink with a moderately broad, black marginal band, the forewings recognizable by the thick, creamy-white basal ray over the proximal margin and a shorter, postcellular, parallel stripe. Mexico, not rare.
- opella*. **E. feronia** Drc. (38 b). Forewing with a similar, white basal ray as in *polyphron*, though it is interrupted below the cell-end by the ground-colour. Hindwings yolk-coloured, broadly margined with black. Mexico (Guerrero).
- rubricosta*. **E. lata** Grt. from Cuba is similar, the basal ray of the forewing not interrupted, but at the cell-end darkened. Hindwings orange. Type in the National Museum of Washington.
- immaculata*. **E. arbela** Drc. (38 c) is larger than the preceding. Forewings wood-coloured, without the basal ray or any other marking, hindwings yolk-coloured, with a blackish-brown margin. Mexico, not rare.
- trimaculosa*.
- sa*.
- intermedia*.
- cocciniceps*.
- parvula*.
- polyphron*.
- feronia*.
- tata*.
- arbela*.

E. metazonata *Hmps.* (38 a). Hindwings of a bright orange-red, the black marginal band narrower *metazonata*, in the middle of the margin. Abdomen bright orange with a black dorsal stripe. Volcans Chiriqui, and Colombia.

E. rogersi *Drc.* undoubtedly approximates the form *brevicornis* of *aurantiaca*, but it is much larger, *rogersi*, almost the size of *metazonata*. Forewings brown, tinted yellow; on the rosy-purple hindwing there is a black spot in the disc and one above the proximal angle. Costa Rica.

E. esula *Drc.* (38 b) is almost like *arbela*, but smaller, the marginal band of the hindwing broader *esula*, and of a deeper black; the brown forewing with an orange-coloured costa. Mexico; apparently rare or very local.

E. fragilis *Strech.* (= *costata* *Stretch*, *opelloides* *Graef*) (38 c). Forewing brown with a reddish-yellow *fragilis*, costal stripe; hindwing unicolorously orange, without the black marginal band. Texas.

E. semirosea *Drc.* (38 a) is one of the largest species; forewing brown with a scarlet costa, hindwing *semirosea*, rosy-red with a broad black distal band being at the middle of the margin sometimes a little notched. Mexico.

E. mathani *Rothsch.* (39 e) from Cundinamarca in Colombia resembles *semirosea*, the forewing deep *mathani*, wooden-brown; hindwings brick-red, the black marginal band narrower near the middle of the margin.

E. laeta *Guér.* (= *treatii* *Grt.*, *rubropicta* *Pack.*) likewise resembles *semirosea*, also with brown *laeta*, forewings and a red costal margin, the hindwings crimson with a black distal half; but the abdomen is likewise dark red with a dorsal row of black spots. South eastern parts of the United States (Florida); distributed also in Arizona.

E. ostenta *H. Edw.* (= *calera* *Barnes*) (38 a). Forewings like in *semirosea*, but the hindwings are *ostenta*, carmine only in the costal areas, otherwise quite black. From Colorado through New Mexico as far as Mexico and Arizona.

E. pomponia *Drc.* (38 a) differs from *ostenta*, which it resembles extremely, by the palpi being black *pomponia*, (not carmine) at the base, and by the carmine costal spot of the hindwing being defined towards the black margin of the hindwing not in a uniform bow, but somewhat angularly. Mexico; very closely allied to *ostenta* as well as *mirma*.

E. mirma *Drc.* (38 b). Above almost exactly like *pomponia*, the red of the hindwings somewhat more *mirma*, extensive; different by the strong black marginal band beneath. Mexico.

E. cetes *Drc.* (38 b) from Oaxaca (Mexico) has the marking and shape of *mirma*, though the bright *cetes* red parts of the latter are here orange-coloured.

E. trigonifera *Schs.* (38 c). The hindwings almost entirely like *cetes*, the costal part more reddish- *trigonifera*, than orange-yellow. Besides, however, the forewing exhibits the whole basal half reddish-yellow, except the blackish-brown proximal margin. Mexico.

C. pamphyllia *Drc.* (38 b) is also from Mexico and similar to *trigonifera*, but the golden yellow extends *pamphyllia*, farther distally at the costa of the forewing.

E. tenuicincta *Hmps.* (38 c). Forewings wood-coloured, the golden yellow hindwings only very *tenuicincta*, narrowly bordered with black. Peru. The southernmost species known of the genus.

E. disparilis *Grt.* (38 d). From Cuba; on the brown forewing some white spots, on the yolk-coloured *disparilis*, hindwing black spots.

E. heros *Grt.* (38 d) likewise from Cuba, is the largest species, quite golden yellow, the forewing with *heros*, duller, the hindwing with somewhat more distinct, dark nebulous spots.

E. pallicornis *Grt.* is another Cuban species, the size of which is between *heros* and *disparilis*. The *pallicornis*, brown forewings are speckled and spotted white, between and towards the margin shaded dark; the hindwings are reported to be dull pink or reddish-orange, with dark spots at the cell-end and above the proximal angle. The butterfly is certainly very rare, unless it be an aberration of *disparilis*; it is not represented in any museum; the type does not exist anymore.

2. Genus: **Virbia** *Wkr.*

This genus with about 20 species is distributed more to the south than the preceding, but it does not occur anymore in the United States. The species are throughout yellow and black, or yellow and dark brown, just like those of the preceding genus were preponderantly carmine. In the structure the *Virbia* are very much like the *Eubaphe*, but they differ by the upper median vein of the forewing branching off with the lower radial from the same place, the lower cell-angle, whereas in the *Eubaphe* the uppermost median vein (which is nowadays often denoted as the lower radial vein) rises far before the lower cell-angle. — Most of the *Virbia* are rather rare butterflies which are nearly exclusively taken by the lamp, only *V. subapicalis* and *medarda* being more

common; most of the species live in Mexico and Central America; nothing is known about their early stages.

I. Forewings unicolorously brown.

- lehmanni*. **V. lehmanni** Rothsch. somewhat recalls *Eubaphe tenuicincta* (38 c), the forewings being also blackish-brown and the hindwings yellow with a uniform black marginal band, but the abdomen is above orange with a broad black dorsal longitudinal stripe, and the distal band of the hindwing is broader. Colombia.
- hypophaea*. **V. hypophaea** Hmps. (38 d). The moderately broad black distal margin of the golden yellow hindwing does not quite reach the anal angle. Forewings bright dark brown; abdomen black with yellow sides. From Costa Rica.
- sanguicollis*. **V. sanguicollis** (= mentions Druce nec Wkr.) (38 d) is like *hypophaea*, but the black distal band runs round the whole hindwing, so that only an orange yellow disc remains below the middle of the costa. Costa Rica.
- subapicalis*. **V. subapicalis** Wkr. (= egaca Wkr.) (38 c) is darker than *sanguicollis*, which it otherwise resembles, but the oval orange spot of the hindwing is not situate below the middle of the costa, but more in the apical part of the wing. Amazon Valley (Ega, Itaituba, Fonteboa etc.), Guiana, Ecuador, to the south in the east as far as Sa. Catharina, in the west as far as Peru; not rare.
- ovata*. **V. ovata** Rothsch. (38 e) greatly resembles *subapicalis*, but it is larger, the yellow spot of the hindwing forms a more oblong oval and is more removed from the apex of the wing. In the ♀ it flows out along the costal margin towards the base. Sa. Catharina.
- medarda*. **V. medarda** Stoll (38 d) is larger than *ovata*. The marginal band of the hindwing does not reach the proximal angle, but it turns round, before it, in a wedge-shaped point, towards the base of the wing.
- minuta*. Distributed in South and Central America and mostly not rare. — **minuta** Fldr. is scarcely more than half as large as *medarda*; the black distal band of the hindwing sometimes extends yet to the proximal margin, after having deposited the black wedge-shaped ray on the base of the hindwing. Mexico, through Central America
- parva*. as far as the Amazon. — **parva** Schs. from Colombia and Ecuador differs from this small form by the black of the marginal band outweighing the orange of the hindwing, so that the latter runs through the hindwing almost like a broad median band. — In the form **mentiens** Wkr. the marginal band of the hindwing is angled at the end of the proximal margin, and the yellow median spot of the forewing beneath is distally cut off
- mentiens*. in a straight line. — **flemmingi** Rothsch. from Ecuador has longer and narrower wings than *mentiens*, the black distal band of the hindwing is of a constant width and the yellow part of the proximal margin does not
- flemmingi*. exactly reach as far as the anal angle, but the marginal band extends as far as the latter. — In **luteilinea** Wkr. (38 e) from Mexico, the size of which is between *medarda* and *minuta*, the yellow inner-marginal part of the ♂ is very broad and cut off quite straight towards the black wedge-shaped ray. This form is presumably identical with *Josiodes inversa* H. Edw. HAMPSON takes most of the forms of this species to be synonyms, whereas according to ROTHSCILD some are of different species. In fact specimens from Muzo differ from those from Villavicencio, the latter from those from Ecuador, Panama or Bolivia in the marginal band of the hindwing and on the under surface, but there are almost everywhere transitions to be found.
- luteilinea*. **V. affinis** Rothsch. resembles *parva* Schs. from Colombia, but the wings are shorter and broader, the yellow occupies almost the whole hindwing and leaves only a marginal band black. The ♀ also exceeds the *parva*-♀ considerably in size.
- affinis*. **V. divisa** Wkr. (38 d) is still larger than *affinis*; the forewings are very dark sepia-brown, almost black; on the hindwing the orange is confined to a broad wedge-shaped spot below the costa and to a minute inner-marginal stripe near the base. Distributed from Nicaragua over Guiana as far as South Brazil and Paraguay; near Rio de Janeiro and Santos not rare.
- divisa*. **V. fasciata** Rothsch. (38 e) from Ecuador and Colombia is considerably larger than *divisa*, with broader forewings, the orange stripe in the hindwing being narrower and beneath not so sharply defined.
- fasciata*. **V. zonata** Fldr. (= distincta H. Edw.) (38 e). On the orange-yellow hindwing a black spot, being in the ♀ below somewhat lobate, in the anal part of the distal margin, and a black stripe from the costal margin round the apex. Mexico.
- zonata*. **V. ampla** Wkr. (38 e). In the place of the black lobate spot there are in the hindwing only some dispersed black, diffuse patches. Likewise from Mexico; *zonata* may be only a form of this species.
- ampla*. **V. rosenbergi** Rothsch. (38 d) is smaller than the preceding are, particularly the ♀♀. All the margins of the hindwing, except the proximal margin, broadly black; this marginal band is very much expanded above the proximal angle. Mexico and Colombia.
- rosenbergi*.

V. satara *sp. nov.* (38 c). Larger than the preceding; the orange spot in the apical part of the hindwing *satara*. is extended in the shape of a crescent. The under surface differs more: the forewings are here not yellow with a broad dark margin as in the preceding species, but black, traversed by a golden yellow transverse band being joined to that of the hindwing, thus producing the design of colours of the Celebes butterfly *Pericallia aequata* Wkr. (Vol. X, t. 24 h) having formerly been denoted as *Satara*.

V. palmeri *Drc.* Forewings dark brown strewn with yellow atoms; hindwings chrome-yellow, with *palmeri*. a broad black marginal band from the apex to the proximal angle, where it is the broadest and deeply notched. Size of the following species. Colombia.

V. epione *Drc.* has an expanse of 36 mm; the forewings are light brown like the thorax, the hindwing *epione*. exhibits a yellow, streak-shaped, distally forked proximal spot and yellow proximal margin. Peru, taken at an altitude of 6000 ft.

V. birchi *Drc.* from Colombia has dark, almost black forewings, and on the black hindwing a central, *birchi*. yellow, wedge-shaped streak from the base to the cell-end. Larger than the preceding.

V. underwoodi *Drc.* is still larger than *birchi* (48 mm). Forewing black, towards the base the darkest. *underwoodi*. Hindwings pale yellow; marginal band in the apical half of the wing quite narrow, in the anal half broad. Costa Rica.

V. rosenbergi *Rothsch.* (38 d) is smaller than the preceding, particularly the ♀♀. All the margins of *rosenbergi*. the hindwing, except the proximal margin, broad black; this marginal band is strongly expanded above the proximal angle. Mexico and Colombia.

V. xanthopleura *Hmps.* (42 h). Chest and abdomen laterally with yolk-coloured stripes. Forewing *xanthopleura*. blackish-brown, strewn ochreous. Hindwing in the ♂ in and below the cell as far as right behind its end with an orange band; another yellow streak at the proximal margin. — In the ♀ there are yellow stripes at the proximal margin, at the base and in the cell. Grenada.

II. Forewings brown, marked creamy-white or orange.

V. thersites *Drc.* (38 e). In the forewing a short, white basal ray and a white spot before the proximal *thersites*. angle; the yellow hindwing with a regular, black distal band. Panama.

V. dotata *Wkr.* (= *lativitta* *Wkr.*) (38 e). Forewings similar as in the preceding species, but the *dotata*. black distal band of the hindwing is strongly narrowed in the middle of the margin. From the Amazon River: Pebas, São Paulo da Olivença, Ega, Manaus.

V. brevilinea *Wkr.* (= *major* *Fldr.*) (38 e). Hindwings entirely like those of *medarda* (38 d), but *brevilinea*. the forewing with a thick, whitish basal ray as far as in the middle of the wing. South Brazil (Rio de Janeiro, Catharina).

V. endophaea *Dogn.* based upon 1 ♂ not lying before me; it has on the chestnut-brown forewing likewise *endophaea*. a spot, but a yellow one being centrally situate so that it is crossed by the median. Hindwing with a yellow longitudinal spot proceeding from the base and leaving the whole margin black. From Corvico in Bolivia.

V. varians *Schs.* represents *endophaea* in Peru; forewing quite similar, but the white basal ray of *variens*. the forewing quite short, often followed by another, small, isolated spot. Cuzco.

V. endomelaena *Dogn.* Size of *medarda* (38 d), but the otherwise brown forewing exhibits a minute, *endomelaena*. creamy-white discal spot; the hindwing with a yellow, central longitudinal spot, something like in *fasciata* (38 e), but broader. From Muzo in Colombia.

V. punctata *Drc.* On the dark brown forewing there is only one creamy-white yellow spot at the cell- *punctata*. end. Hindwings yellow, the black marginal band the broadest at the anal angle. Forewings beneath yellow, margined dark, hindwings similar as above. 36 mm.

III. Forewings black with an orange discal stripe.

V. strigata *Rothsch.* The orange stripe begins about 3 mm distant from the base of the wing and *strigata*. terminates 2 mm before the margin. Smaller than *medarda*. From Surinam and the Tijuca (South Brazil).

3. Genus: **Bricea** *Wkr.*

In the habitus closely allied to the preceding genera, distinguished by the fully developed proboscis, the shorter palpi not being lowered like a snout, but turned up before the face, the abdomen being stout and short. The lowest radial of the forewing does not rise from the starting-point of the middle radial, but before it, though not so far before the cell-end as in *Eubaphe*.

B. disjuncta *Wkr.* (= *jenna* *Bsd.*) (38 c). The blackish-brown forewing with an orange basal ray *disjuncta*. as far as beyond the middle, and two small orange bands before the apex and proximal angle; hindwings with a yellow, distally notched, wedge-shaped spot. Brazil, rare; reported also from Mexico and Central-America.

carpintera. **B. carpintera** Schs. is much smaller than *disjuncta*, black, in the basal half of the forewing orange, only the base itself and a short streak at the base of the costa black; the basal half of the costal margin likewise orange. Costa Rica.

4. Genus: **Heliactinidia** Hmps.

Proboscis capable of function. Palpi quite short, porrect, antennae of the ♂ with rather long comb-teeth. Body much more slender than in *Brycea*, the hindwings rather large. The species belonging hereto differ greatly from each other, but they are all marked yellow, or entirely yellow. They are apparently confined to South America and not common.

- chiguinda.* **H. chiguinda** Drc. (38 f). Hitherto only ♂♂ are known. They are blackish-brown; forewing with a yellow basal ray and a yellow transverse stripe, hindwing with a yellow wedge-shaped spot in the disc and a narrow streak before the proximal margin. Ecuador.
- bimaculata.* **H. bimaculata** Drc. approximates *chiguinda* (38 f). Head, antennae, palpi, tegulae, thorax, and legs black. Collar yellow; abdominal sides yellow. Forewings lighter brown; a yellowish-white postcellular band extends from the costal margin to the anal angle, being broadest at the costa. Hindwings orange-yellow, apex and anal angle broad black. South East Brazil.
- flavivena.* **H. flavivena** Dogn., with an expanse of 31 mm, has brown palpi with yellow bristles at the base. Thorax brown, likewise intermixed with yellow hair; abdomen yellow, with a black dorsal stripe. Forewings above light grey, at the base a yellow spot. Veins well marked, pale yellow; fringes yellow. Hindwings yellow. From Cali in Colombia.
- sitia.* **H. sitia** Schs. resembles *flavivena*; body yellow, with a black dorsal stripe. Forewings olive-grey, with yellowish veins; from the costal margin across the cell-end to the proximal margin, near the anal angle a light shade, on it round the cell-end some small yellow scales; hindwings orange. ♂ 38, ♀ 40 mm. From the Sixola River in Costa Rica.
- coerulescens.* **H. coerulescens** Hmps. (38 f). Black, with a blue lustre, both wings are traversed by a golden-yellow median band, from which a large obtuse ray emerges towards the middle of the margin on both wings. Colombia.
- austriaca.* **H. austriaca** sp. nov. (38 f) resembles *coerulescens*, but on the forewing there is a large, yellow, irregular discal spot; hindwings quite black, without any yellow. The upper surface has a less bright blue lustre than the under surface. Ecuador.
- nigrilinea.* **H. nigrilinea** Wkr. (38 f) is larger, yolk-coloured, with a blackish brown costa of the forewing. South Brazil.

5. Genus: **Pteroodes** Btlr.

One orange-yellow species forms this genus. The 2nd subcostal vein of the forewing anastomoses with the footstalk of the 2nd and 3rd, so that an areola is produced, which is absent in the preceding genus, but occurs again in the following *Haploa*. The structure is slender, the hindwings much smaller than in *Heliactinidia*. Proboscis strong, palpi bent up before the forehead, not lowered as in *Virbia* or *Eubaphe*.

- longipennis.* **P. longipennis** Wkr. (38 f) from Mexico is unicolorously orange-yellow. Costal margin, apex and distal margin finely bordered with black.

6. Genus: **Antiotricha** Fldr.

Forewing without an accessory cell, the discocellulars of both wings longer. Palpi quite short, porrect. In the hindwing the lower margin of the cell is much longer than the upper; proboscis present.

- integra.* **A. integra** Wkr. (= *vexata* Fldr.) (38 f). Unicolorously yellow, but lighter than the preceding, all the wings finely bordered with black. Colombia.
- marcescens.* **A. marcescens** Fldr. (42 i). ROTHSCILD places this butterfly here, for which the genus *Agaposoma* was established by FELDER, and which probably scarcely belongs here. There seem only few specimens to be known, which are at present not accessible to me. As much as we can see from FELDER's figure, which we copy, the venation fits better to the group of the genus *Pachydota*. KIRBY places the species to the *HYPSINAE* (not represented in America). HAMPSON does not mention it in his *Arctiinae*. The rather large butterfly has an orange abdomen banded black, brown forewings and yellow hindwings with a black preapical spot and a hook-like stripe before the proximal margin. Ecuador.

7. Genus: **Hiera** Drc.

Here there is again an accessory cell, considerably larger than that of *Pteroodes*. Systematizers who attach great weight to the accessory cell, therefore, separate this genus far from the preceding genera. We must, however, consider that there are species in which only certain specimens show accessory cells, and that specimens are known being otherwise normally developed, one side showing such a formation, the other not. Hitherto only 1 species is known:

H. gyge Drc. (38 f). Orange-yellow. Costa of the forewing narrow, distal margin of all the wings *gyge*. broadly bordered with black. From the Volcano Chiriqui in Costa Rica.

8. Genus: **Euchlaenidia** Hmps.

Proboscis present. Palpi rising obliquely before the face. ♂ antennae doubly combed. In the forewing the 1st subcostal vein branches off shortly behind the middle, the 2nd before the end of the cell, the 3rd to 5th petioled; the upper radial from the upper cell-angle, the lower one with the upper median vein from the lower cell-angle, the middle median vein rising immediately after it. On the hindwing the middle median vein rises before the lower cell-angle. Based upon 1 species to which later on 2 others were yet added, all of them from South America.

E. transcisa Wkr. (38 g). Forewings brown with a dull yellowish transverse band across the cell-end; *transcisa*. hindwing orange, with a black marginal band being widened in the apical area. Rio de Janeiro; rare.

E. neglecta Roths. (39 f). Forewings similar, but the hindwing orange with a black oval spot before *neglecta*. the proximal angle. A smaller species. Paraguay.

E. ockendeni Roths. (38 f) from Peru likewise resembles *transcisa*, but the light transverse band *ockendeni*. in the forewing is steeper, and the black in the apical and anal parts of the hindwing is narrower.

9. Genus: **Haploa** Hbn.

This genus contains about half a dozen rather similar species changing from white to yellow, mostly marked black; they only occur in North America, and by their frequent occurrence at their habitats, by their habits and even the shape and colour of the wings they superficially recall the palearctic *Nyctemeridae* which are known to be absent in America. It is difficult to define the species, since even in long series of specimens from the same habitat there are hardly two found marked entirely the same (HOLLAND). Scarcely two of the numerous informants fully agree in the homogeneousness of the single forms named, and as the larvae are not yet known of all the forms, the opinions cannot be put to the test. It has also been observed that at the habitats, where a yellow form was met with in crowds and almost exclusively, it was soon hereafter replaced by a white form so completely that not one yellow specimen was discovered among the white ones. — The imagines are rather slim with a small head which, however, is not retracted or as in *Arctia* lowered to the chest, but rests freely on a distinct neck. The eyes are large, bare, ball-shaped, accessory eyes being present. Thorax short, abdomen cylindrical, extending as far as or beyond the anal angle of the hindwing. In the forewing the 1st subcostal vein branches off considerably before the upper cell-end, the 2nd anastomoses with the footstalk of the 3rd to 5th, thus forming a long, narrow areola. In the hindwing the upper median vein comes with the lowest radial from the lower cell-angle. There are 2 peculiar, feather-like, thin appendages at the abdominal end, fluttering in the gentlest current of air and, according to SIEWERS, serving for the flight, which supposition, however, was not verified (in *clymene*). The larvae partly live on trees; the imagines are in some places of frequent occurrence, but local. — There exist several monographies on the genus.

H. clymene Brown (= interrupto-marginata Beauvois, comma Wkr.) (38 g). Forewings bone-yellow *clymene*. with black margins and a black demi-band resting on the proximal margin before the proximal angle; hindwing golden yellow with 1 or 2 black spots above the anal angle. Under surface quite golden yellow, without the black margins, but with the dark demi-band before the proximal angle of the forewing. — Larva, according to SIEWERS (Canad. Entomol. X, p. 84), of a bright yellow with a white lateral stripe; above the latter and at the terminal joint red spotting. On Eupatorium, according to other explorers also on willows. Atlantic states of the Union, distributed from Canada to Georgia, in most of the districts common.

H. colona Hbn. (= carolina Harr., clymene Esp. nec Brown) (38 g) is coloured like *clymene*, but *colona*. the distal area of the forewing is traversed by black stripes in various directions. The golden yellow hindwing with 1 to 3 spots or also without any spot. (Aberr. α — δ with WALKER). The black stripes of the forewing are well developed in typical specimens, but they may be reduced in every direction and have entirely disappeared *conscita*. in specimens exhibiting the least markings: ab. **conscita** Wkr. (= lactata Smith) (38 g). — **reversa** Stretch *reversa*.

(= *suffusa* *Smith*) (38 g) differs from the preceding by the hindwings being white, not golden yellow. Here we may also notice a reduction of the black stripes of the forewing (= *triangularis* *Smith*), to such a degree that *fulvicosta*. only the costa is yet narrowly bordered dark, and this form, ***fulvicosta* Clem.** (= *duplicata* *Neum.* and *Dyar*) (38 g) is even the form described first, so that, in case these forms should be separated specifically (according to HAMPSON, contrary to DYAR), *fulvicosta* forms the name of the species. — Larva black with a lustrous black head, blue tubercles, on which there are few, short, though stiff dark hairs. Across the dorsum a yellowish, interrupted median line being tinged reddish on the rings, beside it feebler, slight subdorsal lines. Lateral stripe broad yellow, in some places broken up into spots. On *Pyrus* and *Prunus*, according to RILEY also on oak-trees. The butterflies are distributed over the Atlantic States of North America, being common in Texas, growing rarer to the north. In the south they occur already early in May.

lecontei. **H. lecontei** *Bsd.* (= *leucomelas* *H.-Schäff.*) (38 g). Typical specimens have an entirely white ground-colour; the forewings are margined with black and exhibit a dark oblique band from the apex towards the distal part of the proximal margin, a white oval in the apex and a small cell-end band from the costa. — In *militaris*. ***militaris* Harr.** (= *harrisii* *Dyar*) the oblique band of the forewing is once or twice interrupted, and the *confinis*. ground-colour in the ♂ is sometimes tinted creamy-yellow. — ***confinis* Wkr.** has a complete oblique band, but *smithii*. the marginal bands of the forewings are reduced. — ***smithii* Dyar** exhibits the dark stripes interrupted as well *dyari*. as of an irregular course. — In ***dyari* Merrick** there are no dark markings at all; the insect is unicolorously bone-yellow, so that it may only form a transition to the following species, which is regarded by some (DYAR, HOLLAND) to be merely another form of *lecontei*. — Larva black with a bright yellow dorsal and a similar lateral line (STRECKER); it lives on *Triosteum perfoliatum*, and wherever this is growing abundantly, the butterflies are often met with in big crowds at the end of May and beginning of June. Atlantic States of the Union, from New England to Georgia, and to the west as far as the Mississippi.

vestalis. **H. vestalis** *Pack.* Size somewhat smaller than that of the form *dyari* of *lecontei*, which it also resembles, though it is altogether white, not bone-yellow, all the wings being void of markings, except the costa and border being faintly bordered dark at most. Atlantic States. Presumably only a form of *lecontei*.

confusa. **H. confusa** *Lyman* (38 h). In this species the stripes of the forewings form a whole net leaving the ground-colour free only in 5 larger and some smaller spots. Hindwings of a pure white. — Larva when grown up black with yellow lines in the middle and at the sides of the dorsum; lateral rows of partly obsolete light *lymani*. dots. On *Cynoglossum officinale*. — In the form ***lymani* Dyar** the markings are reduced and more interrupted; otherwise the form seems to be constant. In the northern (New England) States.

contigua. **H. contigua** *Wkr.* (38 h) is entirely white, the margins of the forewings black; a black, postmedian, *lumbonigera*. transverse band sending forth a branch below the middle of the margin. — In the form ***lumbonigera* Dyar** the *ra*. distal band is absent. Atlantic States; in July.

10. Genus: **Utetheisa** *Hbn.*

The forewings more stretched, narrower and longer, the costa more curved, the margin shorter. A cosmopolitan genus found not only in all the 5 continents, but also in numerous islands. As to further particulars see Vol. II, p. 73, and Vol. X, p. 260. America has 3 species.

ornatrix. **U. ornatrix** *L.* (38 h). White, forewing tinged rosy with small red spots along the costal and distal margins, before and between which there are few black dots. Hindwing in the distal part with black, confluent spots, which in the ♂ are more confined to the marginal area, while in the ♀ they often occupy more than half *stretchi*. the wing. — ***stretchi* Btlr.** (= *pura* *Btlr.*) has more numerous, small, black dots on the forewing, which also penetrate the disc in rows, the hindwing being tinted rosy-red as far as the median. From South Florida and the Antilles through Mexico, Central and the whole of South America as far as Argentina, in some districts very common, flying almost throughout the year.

bella. **U. bella** *L.* (38 h). On the forewing orange-red transverse bands alternate with white ones being *intermedia*. dotted black; hindwings purple-pink, irregularly margined with black. — In the ab. ***intermedia* Btlr.** the under surface being otherwise red with black markings, is also spotted white, and on the hindwing above there is *hybrida*. an interrupted spot before the marginal band. — ab. ***hybrida* Btlr.** has the hindwings above in the distal half *terminatis*. more broadly margined dark, and much more black on them, whereas in ab. ***terminalis* Neum.** and *Dyar* the marking in the disc of the forewing is lighter, and the ground-colour of the hindwing white instead of purple or pink. — In the Atlantic States often common, to the south as far as Mexico and Yucatan, flying in autumn *venusta*. and sometimes till November. — In the Antilles there occurs a local form, ***venusta* Dalm.** (= *speciosa* *Wkr.*); instead of the orange bands on the forewings, it is coloured crimson or miniate, and the black marginal band of the hindwing is much narrower. — The larva lives on *Myrica gale*. It is black, speckled yellow and white, across the dorsum darker, with a lustrous red-brown head and leather-coloured ring-indentations. Under-side leather-coloured; hairing dark, thin, bristly. The larvae of the Antilles-form *venusta* are coloured orange with black transverse bands (PACKARD).

U. galapagensis *Wlgr.* (38 h) is a small species, having so far only been found in the Galapagos. *galapagensis*. Dirty whitish-grey. Forewing in the basal part tinted yellowish-brown, with a similar band-stripe through the middle and before the margin. In the disc traces of red colouring. Hindwings distally yellowish-brown, towards the base lighter, without the black marginal band.

11. Genus: **Dodia** *Dyar.*

This genus, entirely unknown to me, was established for a single species discovered in the west of Canada, recalling *Parasemia plantaginis* by its size and wing-contours, though the colouring and marking is quite different. The cell of the forewing has almost $\frac{3}{4}$ the length of the wing, the cell of the hindwing $\frac{3}{4}$ the length of the wing. On the hindwing the discocellular is concave, but not angled, and veins 3 to 5 (the upper medians and lower radial) emerge from the lower cell-angle. Proboscis feeble, ocelli large, body slender, Geometrid-like. Posterior tibiae with 4 spurs, anterior tibiae with a terminal prong.

D. albertae *Dyar.* The butterfly being preponderantly yellowish-brown is so far only known from *albertae*. the District of Alberta. The transparent grey forewing exhibit, beside the dark veins, whitish, undulate subterminal lines; base of the wings suffused whitish, forewing with a grey, curved subbasal and a grey, slightly undulate median oblique band. Hindwings semi-diaphanous. Expanse of wings: 34 to 35 mm. Taken in June and July.

12. Genus: **Kodiosoma** *Stretch.*

This genus contains only 1 small Californian species somewhat resembling the palearctic *Ocnogyna* by its shape and habits, though the ♀ is winged, as much as we know. Like in the *Ocnogyna*, the *Kodiosoma* are without a proboscis; the head is hidden in woolly hair, and the palpi, likewise shaggily haired, are porrect. The venation of the forewing only differs from that of *Ocnogyna* by the 2nd subcostal vein being petioled with the 3rd to 5th in the latter genus, whilst in *Kodiosoma* it branches off before the cell-end. No areola.

K. fulva *Stretch* is to be recognized by the snow-white collar separating the dark head from the *fulva*. brown thorax. The wings are thinly scaled, the hindwings even semi-diaphanous. In typical specimens the abdomen and hindwings are orange-yellow; in ab. **tricolor** *Stretch* (38 h) the hindwing is dull rosy-red; in **eavesi** *tricolor*. *Stretch* (38 h) the abdomen and hindwings are blackish, and in **nigra** *Stretch* the abdomen is orange-yellow only *eavesi*. *nigra*. at the apex; it otherwise resembles the preceding. Distributed in California and not rare.

13. Genus: **Ocnogyna** *Led.*

This genus, being otherwise purely palearctic, has been dealt with at large in Vol. II, p. 76 to 78, and Vol. X, p. 237. A small butterfly from South America is said to belong here. Neither OBERTHÜR, who described the species first (as *Arctia*), nor HAMPSON, who inserted it in the *Ocnogyna*, knew the ♀ of which we, therefore, do not know whether it is fully winged or not.

O. jelskii *Oberth.* (38 h). Unicolorously blackish-grey, thinly scaled. Anal tuft with yellow hair. *jelskii*. Peru. Middle of August.

14. Genus: **Laora** *Wkr.*

Entirely of the character of the antarctic *Arctiinae*: long ♂ antennae strongly feathered, and insignificant dull colours. Head and body densely haired, palpi long, haired brush-like, extended straight forward. On the forewing the 1st subcostal vein rises far before the cell-angle, the footstalk of the 2nd to 5th emerges with the upper radial from the upper cell-angle.

L. antennata *Wkr.* (38 i). Dark red-brown, thorax and abdomen anteriorly mixed with yellow hair. *antennata*. Hindwing greyish-brown, at the base tinged yellowish. Abdomen with dark bands, being, however, in the ♂ covered by the long woolly hair. Colombia, though at great altitudes, as for instance near Bogotá, 3000 m.

L. ubiana *Drc.* (38 i) is similar, but larger and more unicolorously reddish-brown. Panama. The *ubiana*. ♀ of this species is unknown to me.

15. Genus: **Phragmatobia** *Steph.*

For the genus itself comp. Vol. II, p. 79. In the restricted sense as considered here, it differs from the following genus, as well as the preceding genus, by the almost plain antennae. It contains only about half a dozen species in the palearctic and nearctic regions.

Ph. fuliginosa *L.* Entirely typical specimens (Vol. II, t. 16 b) hardly occur in America. Examples from there, 6 of which are before me from my collection, are throughout darker and very thinly scaled. The

- rubricosa*. nearctic specimens have been denominated: **rubricosa** Harr. (38 i), which name, however, is not generally acknowledged, because also in the palearctic region there occur all the transitions from the brightly coloured, densely scaled form *fervida* Stgr. to the northern *borealis* Stgr. which is very closely allied to *rubricosa*. As to further particulars about it and the larva see Vol. II, p. 79. — *rubricosa* is very numerous in Canada and the northern parts of the United States and frequently captured by the lamp. To the south the species extends as far as Carolina, but there it does not occur anymore in the plains, being confined, like in the west to the Rocky Mountains, in the south to greater altitudes.
- assimilans*. **Ph. assimilans** Wkr. (38 i). Almost like the European *fuliginosa fervida* (Vol. II, t. 16 b), but sometimes without any dark nebulous spots at all, with unicolorously brown-red forewings and rosy-red hindwings. New York, New England, on mountains. — **franconiae** Annie Slosson (38 i), described from a ♀ taken by the lamp on May 24th near Franconia, shows traces of dark transverse stripes on the forewings and a blackish marginal band before the margin of the hindwing.

16. Genus: **Neoaretia** Neum. & Dyar.

It rather precisely corresponds to the palearctic genus *Micraretia* (Vol. II, p. 83), from which, however, it differs by the finer antennae, which are not so feebly ciliated as in the ♂♂ of the *Phragmatobia*, being provided with almost plain antennae. The venation does not exhibit any essential difference, for which reason HAMPSON combines the genus with the preceding. We include here 6 forms, nearly all from North America. Perhaps also the species *thursbyi* Roths. (39 l) having been described as *Turruptiana* is to be included herewith; as to further particulars about the latter species unknown to me in nature see p. 313.

- beanii*. **N. beanii** Neum. (38 i). Colouring almost like in the aforementioned *Phragmatobia*, but across the forewing and hindwing there extend sooty black nebulous stripes and spots. Rocky Mountains of Alberta and Assiniboia. — In the form **fuscosa** Neum. the forewings are quite covered with blackish.
- brucei*. **N. brucei** H. Edw. (38 i). Forewings crossed by pinkish-yellow bands and spots. Collar broad pinkish-yellow; hindwings with large, black antemarginal spots. Colorado.
- fervida*. **N. fervida** Wkr. (= *rodriguezi* Drc.) (38 k). Forewings blackish-brown, whitish colour pervading them; hindwings of a bright red with a broad black distal band. — In the form **commixta** Btlr. (38 k) the white streams on the forewing are reduced to a proximal longitudinal stripe and a distal oblique stripe. From Guatemala.
- garowii*. **N. yarowii** Stretch (= *remissa* H. Edw.) (38 k). Forewings black, a dull yellowish-white pervading them, hindwings orange, with black discal spots and a dark basal area. From the districts to the south of the Hudson Bay as far as British Colombia; in the Rocky Mountains it extends far to the south, as far as Arizona.

17. Genus: **Hoplarctia** Btlr.

Proboscis stunted, palpi very short with a minute terminal joint. Antennae bristly; face very short, with appressed hair; body rather slender. Venation entirely like in the preceding genera; in the forewing the 1st subcostal vein rises before the cell-end, the footstalk of the 2nd to 5th from the upper cell-angle, from the same place also the upper radial. Only 1 species:

- hodeva*. **H. hodeva** Drc. (38 i). Thorax brown with white collar and shoulders; forewing dark reddish-brown with a white oblique band sending forth a connecting band towards the base of the wing. Hindwing crimson, with a uniformly black margin. The type originates from Jalisco in Mexico *).

18. Genus: **Orodemnias** Wallgr.

Already in Vol. II, where we described this genus, we have stated that it almost unnoticeably forms a transition to the next genus, for which reason also the modern authors insert it simply in the genus *Apan-tesis* (being older by 11 years). Since the veins do not exhibit any characteristic marks in the *Arctiinae*, some *Orodemnias* were brought into connection with *Micraretia*, others with *Parasemia* or *Phragmatobia*: STAUDINGER and REBEL simply insert them in the *Arctia*. As the type *O. quenselii* is considered.

- gelida*. **O. quenselii** Payk. (Vol. II, t. 16 g) occurs in the typical form in Europe. The American form: **gelida** Mschlr. (38 k), described from Labrador, differs from the type by the forewings exhibiting much more yellowish-white and by the hindwing showing a light, wedge-shaped stripe before the proximal margin. — *complicata*. In **complicata** Wkr. from the western coast of Canada (Vancouver) the transverse stripe running through the cell, being sometimes hinted at in *gelida*-♀♀, is present also in the ♂, passing through as far as the submedian,

*) As another *Hoplarctia*, *H. nantana* was described by BUTLER. It is, however, a genuine *Ctenucha*, and has been dealt with on p. 190 of this volume, though not figured; we, therefore, add here the figure (38 k).

the same being the case with the band behind the cell-end. For further particulars about *quenselii*-forms and the larva comp. Vol. II, p. 82. — The species occurs besides in Greenland and other parts of Arctic America.

19. Genus: **Apantesis** Wkr.

This multiform genus forms one of the greatest attractions of the nearctic butterflies. More than 80 names have been given to forms of this genus, and if one would, as has been unfortunately done with its palearctic allies, denominate every variation in the spotting of wings or body, the number of *Apantesis* could easily be trebled. In American works the genus is often denoted as *Arctia*; this, however, can only be done where the *Arctia caia*, which cannot be dealt with congenerically with the *Apantesis*, is denoted as „*Euprepia*“, „*Chelonia*“, or „*Hypercomba*“. Among the palearctic forms, the *Apantesis* are, beside the *Orodemnias* which are, as we mentioned, often inserted in the *Apantesis*, approximated by that genus for which we employed in Vol. II the name *Euprepia*, containing the species *Eupr. pudica*, *rivularis* and their allies.

The butterflies mostly show on the forewing yellow latticed markings pierced by black, out of which a light longitudinal streak on the submedian vein and a large reclining W in the marginal area are distinctly prominent. The hindwings are mostly red, which often turns honey-yellow in aberrative forms, with black spots or a black marginal band. The abdomen almost invariably shows the red or orange-yellow warning colour suggestive of interior oily secretions which are ejected from openings at the neck, on the insect being disturbed. The butterflies are consequently not adapted, but rather conspicuous. But as the most brightly coloured forms, such as *A. arge*, are resting directly on the soil, deep in the grass, the animals are anyhow not so easily found as might be thought. Nor are they so easily chased up nor are they so heliophile as for instance the palearctic *Callimorpha*, although some are often met with flying in day-time. On seizing them, some species (or all?) utter a stridulous sound, whilst when flying past our ears we hear a noise like the cracking noticed in *Callimorpha dominula* or *Parasemia plantaginis* flying past us.

The larvae are real bear-caterpillars, i. e. densely covered with stiff hair, often like our *Spilosoma* with coloured longitudinal stripes. They are not dainty in their food, and most of them may be bred with lettuce or the leaves of the common lettuce. If one wishes to protect the small larvae, having crept out from the eggs, against infectious diseases, they must, beginning from the 3rd skinning, be separated in small groups in different receptacles, so that at the time of their pupation not more than 2 or 3 remain in one receptacle. On giving them succulent food, I could not notice an inclination to cannibalism, as is reported of different Arctiid larvae. Breeding is very easy, since many larvae — at least in one generation — do not hibernate.

Like in the Old World the magnificently coloured *Arctia* preponderantly live in the temperate north and are replaced towards the south by the more monotonous *Spilosominae*, the *Apantesis* are also the most common in South Canada and the northern parts of the United States, decreasing so quickly towards the south that only 2 species reach yet Mexico. In most of the places of the temperate North America we may reckon to meet with about half a dozen of *Apantesis*-species. Thus HAIMBACH mentions 6 species for Five-Mile-Beach in New Jersey, and 3 or 4 species were met with in different districts already when collecting at a short stay. Even of those species, the imagines of which are rarely met with, the larvae are mostly common, and that is why the prices of most of the *Apantesis*-species are comparatively low, in spite of their great popularity with collectors.

A. blakei Grt. (38 k). This small form from the Rocky Mountains and the Californian Mountains *blakei*, greatly resembles the *Orodemnias quenselii* by its size and habitus, but the hindwings exhibit a bright yellow ground-colour, and the latticing in the forewing is somewhat differently arranged. — **bolanderi** Stretch from *bolanderi*, the Sierra Nevada and the Rocky Mountains is regarded by some as identical with *blakei* (DYAR), by others as a distinct species (HAMPSON); it differs, besides other marks, by the hindwings being red or very much tinted red.

A. ornata Pack. (= *simplicior* Btlr.) is another form of the size and about of the exterior of *O. quenselii*, *ornata*, varying greatly, for which reason it was given quite a number of names. In the typical form the yellow-veined forewing is traversed by 3 light transverse bands: before, in and behind the middle. Besides there is in the marginal area a reclining W. The hindwings are in normal specimens scarlet, marked black, at the proximal margin orange-red. — In the form **perpicta** Dyar the innermost whitish transverse band of the forewing is absent, *perpicta*, whilst in **achaia** Grt. & Rob. (= *dahurica* Grt.) (38 k) it is still indicated, being broad and in some places even *achaia*, double in **edwardsii** Stretch (38 k). In all these forms the ground-colour of the hindwings is red. — **ochracea** *edwardsii*, *ochracea*, *sulphurica*, Stretch (= *barda* H. Edw.) has orange-yellow hindwings, the forewings being similar. — Also **sulphurica** Neum. *sulphurica*, (= *elongata* Stretch) has yellow, instead of red hindwings, but the light vein-stripes of the forewings are narrowed or in some places obsolete. — In **obliterata** Stretch (38 k), having again scarlet hindwings and being perhaps *obliterata*, a distinct species (the patria of this form is unknown), the vein-stripes of the forewings are noticed to be fine whitish, but the light transverse bands are absent. — The egg is light yellow, quite smooth, in the shape of

a flat cone with a smooth base. The fully developed larva is above black with a red-brown dorsal stripe, with black tubercles on which there are black bristly hair; underside dark brown, speckled lighter. On Plantago, clover, Erodium and many other low plants. Except the last, more deviating form, all the *ornata*-forms come from the western coast of North America, where the species is local from British Colombia to California, but in some places not rare. In the collections we most frequently meet with *achaia*, then *ornata*, more rarely *edwardsii* and *obliterata* is not to be found even in large collections of North America.

williamsi. **A. williamsi** Dodge (38 m). Forewings similar to those of the other *Apantesis*, but the species is immediately recognizable by the dirty greyish-brown hindwings exhibiting only round the cell-end and before the proximal margin light cuneiform spots often tinged pink. — In **determinata** Neum. (= *dieckii* Neum.) (38 m) the forewing has besides a middle transverse band which is absent in typical *williamsi*. To the west of the Rocky Mountains, from British Colombia to the south as far as Nevada and Colorado, in some places common, though more in the mountains.

tooele. **A. tooele** Bs. & McD. from Utah approximates *williamsi*, but it is larger, the hindwings more brilliantly coloured. Forewings deep brown with red-yellow veins and longitudinal bands. Of the transverse bands that near the base and the submedian one are absent, the middle and distal ones being present, the W large. In typical specimens the thorax is marked reddish-white, in the form **ophir** Bs. & McD. it is quite black.

oithona. **A. oithona** Streck. (38 m). The forewing exhibits light bands at the costal margin, proximal margin and along the submedian, transverse bands in and behind the middle, which, however, do not cross the submedian, as well as the reclining W in the marginal area. Hindwings rosy-red with black-spots. — In typical *oithona*, from the eastern parts of the United States, the light bands of the forewing are broad, in the form *rectilinea* French (38 m) they are narrower. The butterflies in May, to the south perhaps twice a year.

phyllira. **A. phyllira** Drury (= *b-atra* Gz., *plantagina* Mart.) (38 m) differs from the preceding species chiefly by the larger, wide-spread W of the marginal area of the forewing. The light patches are considerably narrower and thereby the dark spots of the ground-colour larger. The light transverse stripe in the middle of the forewing has also a different direction, extending from the costa to the submedian distally, in *rectilinea* proximally. The fringes of the wings are dark pink in *phyllira*, whilst in *oithona* they are mostly bright yellowish-white. — In *dodgei*. **dodgei** Btlr. the middle band of the forewing is absent, the distal one being several times interrupted. — In *figurata*. **figurata** Drury (= *ceramica* Hbn., *F-pallida* Streck.) (38 m) the middle band is mostly well developed, but the *excelsa*. W in the marginal area is absent (particularly often in the ♀♀), or only a V is faintly seen. — In *excelsa* Neum. (= *lugubris* Hulst) the light bands of the forewing are incomplete, the hindwings entirely or almost entirely black. — *celia* Sndrs. (= *franconia* H. Edw.), perhaps a distinct species, has more yellow than red hindwings. — A very peculiar form is **favorita** Neum. (38 m) in which the light stripes of the forewings are expanded to broad, confluent spots; the black cell-end spot in the hindwing is absent. Various authors took either form to be a distinct species, but ROTHKE succeeded in breeding very differently coloured specimens from the very same eggs *). — The fully developed larva is black, with greyish-yellow tubercles on which there are tufts of light brown bristles. Across the dorsum extends a light (yellowish-brown or yellowish-grey) median streak interrupted on the segmental indentations. On Helianthus divaricatus, lettuce and many other low plants. — In the southern parts of the United States, e. g. Georgia, Virginia etc., not rare.

virgo. **A. virgo** L. (38 l) is the largest, most beautiful and longest known species of the genus. Forewings black with yellowish-white, in the ♀ pink veins and margins, a whitish band across the cell-end, being bent at the median, and a large W-stripe in the marginal area. Hindwings in typical specimens of a bright red, in the (rare) form **citrinaria** Neum. yellow, with black spots surrounded by a lighter colour. The black cuneiform spot filling up the cell of the forewing may be undivided like in the figured specimen taken in the Catskill Mountains on August 15th; mostly, however, it is divided by another whitish band into a longer proximal spot and a rectangular distal spot. Among the numerous specimens before me there are hardly 2 alike, and the species could be just as variedly and uselessly denominated, as it was done in *Arctia caia*. — Larva dark brown with a light-yellow marked head and whitish-grey dorsal tubercles bearing tufts of brown bristles; on Chenopodiaceae and many other low plants. Pupa slate-grey, the ankles and sutures black. The species occurs more to the north, being not rare in Canada, Maine, Massachusetts and the other north-eastern states, and being found in particularly great numbers in the Catskill Mountains (New York). Flying in July and August.

parthenice. **A. parthenice** Ky. (= *saundersii* Grt.) (38 l). Coloured almost like small *virgo*-specimens, but the white bands of the forewings narrower and scantier. On the red hindwings the black spots in the disc (particularly the large one above the middle of the cell) are entirely absent except a small spot at the cell-end, or they are only indicated; mostly there are only some small spots at or near the margin. — Also in this species single bands of the forewing may be absent and the vein-stripes narrowed. There are here likewise numerous insignificant variations in the spotting (*approximata* Stretch. etc.). Canada and the Atlantic northern

*) M. ROTHKE at Scranton has evidenced the enormous variability of this butterfly (Iris 26, t. 1) by breeding the eggs of it. He yielded from the same breed imagines with only scantily red-spotted hindwings and also such, in which they did not exhibit any real black margins. — GRAEF (Bull. Brookl. Soc. 1, p. 3) had already before obtained similar results, from which he inferred *Ap. saundersii*, *persephone* and *anna* to belong together in an analogous way.

parts of the United States; in the south the species is represented by the form **intermedia** *Stretch* (= *stretchii intermedia* *Grt.*) (38 l) being particularly common in Texas. It is larger, with glaring light-red, instead of purple-red hindwings, very broad stripes on the forewings and is considered by some authors (DYAR, HOLLAND) to be a distinct species.

A. virguncula *Ky.* (= *speciosa Mschlr.*, *dahurica Grt.*) (39 a). In typical specimens of this species the *virguncula* transverse bands on the forewings are absent, except the antemarginal W, the hindwings are quite pale yellowish-red and very abundantly spotted black. — In the form **otiosa** *Neum. & Dyar* also the light transverse bands *otiosa* in the disc are more or less developed and our figure already forms a slight transition to it. Canada and the north-eastern parts of the United States, not rare.

A. anna *Grt.* This is the rare form with quite black hindwings, of which **persephone** *Grt.* (39 a) con- *anna.* *persephone.* stitutes the more common normal form; the latter has the hindwings only half black or with many large black spots. The forewings are almost exactly like those of *virguncula*. — Larva blackish-brown; when grown up it has a black head and a light dorsal and lateral line; the tubercles are lustrous black, on them tufts of dark bristles, 2 hairs on the anal part white. On Polygonum and numerous other low plants. Atlantic States, the form *persephone* not rare.

A. vittata *F.* (39 a). Forewings black with cream-coloured margins and similar stripes on the median, *vittata* across the cell-end a white oblique band ending in the ♀ at the median, extending in the ♂ into the W of the marginal area (which is mostly absent in the ♀). Hindwings reddish yellow-white, at the margin and before it somewhat spotted black, in the ♀ sometimes the whole marginal area black (= f. **decorata** *Sndrs.*). — *decorata.* In **ochreata** *Btlr.* (39 a) the hindwings and abdomen are golden yellow, without any reddish tinge. — In **incompleta** *Btlr.* (= *colorata Wkr.*) the upper arm of the marginal W is absent, and in **radians** *Wkr.* (39 a) the W is absent *ochreata.* *incompleta.* altogether, and the ♀ has only a white basal ray in the black forewing. — **phalerata** *Harris* (= *rhoda Btlr.*) *radians.* *phalerata.* (38 m) are deviations of this extremely variable species, but HOLLAND states that he obtained the most various forms all from the same place, a small valley in Pennsylvania. *phalerata* has fine, though distinct white stripes on the forewings, being complete also in the ♀; the hindwings are rosy-red with large black spots. Atlantic parts of the United States, from the Canadian frontier to Florida. The species is very common; *phalerata* is distributed through Mexico and Central America to Costa Rica.

A. nais *Drury* (= *cuneata Gz.*, *defloriana Mart.*) is presumably not to be separated from the preceding, *nais* being closely allied to *ochreata* from which it chiefly differs only by the yellow abdomen with very few spots above. Range as in *vittata*, but still more common.

A. placentia *Abb. & Sm.* (= *quadrantata Streck.*) (39 a). Forewings black; a white spot in, one *placentia.* behind the cell, and some in the marginal area, where there are often; traces of the W. Hindwings dark red with some black spots. — **snowi** *Grt.* shows the black spots of the hindwing increased so much that they occupy *snowi.* the greater part of the wing. — In **flammea** *Neum.* the white spots of the forewing are somewhat increased. — *flammea.* Larva blackish-grey, with dark, brown-haired tubercles, a yellow, reddish spotted dorsal stripe and on both sides of the latter dark, interrupted dorsal lines. On blackberries and many other low plants. Pupa light brown, with dark markings. Southern States: Mississippi, Texas, Alabama, Georgia. Not common.

A. nevadensis *Grt. & Rob.* (= *behri Stretch*) (39 a). In this species particularly the light transverse *nevadensis.* bands of the forewing are well developed. In the ♂ often already the base of the wing is pinkish-white, then follows a subbasal, median and postmedian band with the latter of which the marginal W flows together. The delicately rosy-red hindwing at the margin with a row of black spots. — **incorrupta** *H. Edw.* (= *shastaënsis incorrupta.* *French*) (39 b) is larger, more brightly coloured, the patagia more distinctly surrounded with white, the spots of the forewing almost like in the European *Euprepia pudica* which the animal also resembles on the whole. — **superba** *Stretch* (= *geneura Stretch*) has distinct but narrow bands of the forewing, the black marginal *superba.* spots of the beautifully red hindwings flow together to a black marginal band. — The species occurs in the Rocky Mountains, as well as the Californian Mountains, *incorrupta* being the more common form.

A. michabo *Grt.* (38 l). Forewings marked almost like in *virgo*, but the light bands of a beautiful flesh- *michabo.* colour; the transverse bands broad, a thicker costal band usually filling up the whole subcostal space, in the distal half of the forewing a broad, rosy flesh-coloured X. The hindwings light red, thickly spotted black, one large spot passing through the middle of the cell, as in *virgo*. Beneath the animal is magnificently light red and black; sometimes there even occur specimens in which also the upper surface, beside the black spotting, only yet shows fiery red colour: ab. **minea** *Slosson*. Distributed in the eastern states, particularly in *minea.* Texas, but in many places rare.

A. arge *Drury* (= *dione F.*, *incarnatorubra Gz.*, *nerea Bsd.*, *caelebs Mart.*) (38 l). On the forewings *arge.* the light bands are so much increased and widened that all are confluent, the black ground-colour appearing only yet in a number of dispersed, small cuneiform spots. Hindwings in the ♂ more thinly, in the ♀ more densely spotted black. — In the form **nervosa** *Neum. & Dyar* the black spots of the forewings are still better *nervosa.* preserved and represent chains of triangles and quadrangles; the light transverse bands of the forewing are

mostly absent. — The larva is dark brown with a very broad yellow dorsal stripe, spotted reddish, and a light yellow postdorsal and lateral stripe. On *Plantago* and other low plants, easily bred with dandelion and lettuce. From the eggs of one and the same ♀ I obtained quite pale and very beautifully flesh-coloured imagines. Most anywhere in the United States from New York to California, beside *nais* and *virgo* the most common species of the genus; in July.

- proxima.* **A. proxima** Guér. (= *docta* Wkr., *mexicana* Grt. & Rob., *arizonensis* Stretch, *mormonica* Neum.) (39 b). Both sexes quite different. ♂ dull yellowish-white, on the forewing some black triangles and quadrangles; proximal margin of the hindwing tinged rosy. ♀ with much larger black spots separated by transverse and longitudinal bands; hindwings purple-red with large, often confluent marginal spots. — **antheola** Bsd. (= *autholea* Bsd.) is the name of specimens showing also in the ♂ the hindwings very much spotted black. — This is the southernmost species of the genus, distributed from California and the Rocky Mountains to the south through Mexico and Central America as far as Costa Rica, everywhere common.
- cervinoides.* **A. cervinoides** Streck. A very small species, scarcely half the size of *quenselii*, reported to originate from Colorado. Thorax striped white, abdomen black with whitish sides. Forewings blackish-brown, the bands as usually whitish, hindwings white with short, small, dark stripes at the base, a blackish cell-end spot and blackish marginal band. Unknown to me.

20. Genus: **Parasemia** Hbn.

To the description of the genus in Vol. II, p. 81 we may add that the proboscis is stunted and the forewing provided with an accessory cell. The genus only contains one species: *plantaginis* L., being also distributed over North America.

- plantaginis.* **P. plantaginis** L. Of the palearctic forms, of which almost 30 are denominated up to this day, some also occur in North America and have partly been newly named there. — **geometrica** Grt. (39 b) has black hindwings; on the forewing the band above the proximal margin and the distal stripes, which, though interrupted in the otherwise similar (Asiatic) form *nyctitans* (Vol. II, t. 16 e), are complete and confluent among each other. — **petrosa** Wkr. (39 b) shows a beautifully royal-yellow discal area in the ♂ hindwing, the basal part and marginal band being black; from California. — The species is common almost at all its habitats. As to the larva and its habits see Vol. II, p. 81.

21. Genus: **Leptarctia** Stretch.

Only a single though very multiform species forms this genus. Proboscis stunted. Palpi straightly porrect, below bristly haired. ♂ antennae doubly combed, the pinnae something like in *Parasemia*. The forewing without an accessory cell, the discocellular on both wings angular. On the forewing not only the 1st, but also the joint footstalk of the other subcostal veins rise before the cell-end. Remarkable is a vast sexual dimorphism.

- californiae.* **L. californiae** Wkr. The typical specimens have grey, darker shaded forewings and orange-yellow hindwings, spotted dark near the margin, quite similar to the figured form **lena** Bsd. (39 b) from which, however, they differ by exhibiting besides some blackish markings also in the disc of the hindwing. The figured ♀ of *lena* originates from Colfax at the foot of the Sierra Nevada; as the ♂ belonging to it, a specimen was taken there on the same day (July 7th) with almost quite black hindwings only marked with a dull yellow postmedian band: this belongs to the form **dimidiata** Streck. (39 b) in which, however, also the hindwings may be quite black. — **fulvofasciata** Btlr. has likewise grey, dark shaded forewings; the yellow band in the hindwing, however, occupies almost the whole median area. — **decia** Bsd. (39 b) is marked almost like a *brephos*, but the ground-colour of the hindwings is a deep ruby-colour. — **latifasciata** Btlr. is the same, but the whole basal part of the hindwing is black. — **boisduvalii** Btlr. has quite similar hindwings marked orange and black, the forewings, however, show an irregular, whitish postmedian band. — **stretchi** Btlr. has similar forewings, but the hindwings are either quite black or they exhibit only very faint orange traces. Between these forms there also occur transitions which, like some extremes, have received denominations which are, however, superfluous or are to be considered as synonyms, such as *adnata* Bsd., *occidentatis*, *wrightii*, *albifascia* French. All the forms live — often occurring beside each other — in South California, where they are mostly common, flying in spring and summer. The forms mostly in request in the trade are, beside the type, *dimidiata* and *lena*.

VI. Spilosomini.

This group having been dealt with at large on p. 84 of Vol. II is characterized by the dorsal spots on the abdomen, which, however, also occur in many other Arctiid genera not belonging hereto. As we have emphasized in Vol. II, we do not acknowledge here a subfamily being systematically definable, as it was

established by KIRBY in his Catalogue of the Night-Butterflies (Vol. II, p. 224), but we keep up the name of the group with slight changes, so as to facilitate their survey. Instead of 38 genera with 245 species we enumerate here 22 genera containing 220 forms. The homogeneousness of the *Spilosomini* (*Spilosomatinae* Ky.) is exhibited more by the larvae than by the imagines. In contrast with the *Callimorphini* they are more abundantly and more densely haired, compared with the *Phaegopterini* more uniformly, and with the *Pericopini* more softly haired. The *Hypsini* (*Aganaidi*), being much lighter haired, so that the larva appears to be almost bare, have also a different shape, and are lazy animals in their larval stage whereas the larvae of the *Spilosomini* exhibit a most remarkable agility, which even influenced their denomination (e. g. *lubricipeda*). Both as imagines and larvae, they are most closely allied to the genuine *Arctiinae* and to the allied *Micrarctiinae*, for which reason we place them between these two groups. Their geographical range is universal. The single genera reckoned hereto are so closely allied to each other that HAMPSON, in his „Catalogue“, combined more than 30 to one single genus — *Diacrisia*.

1. Genus: **Spilosoma** Steph.

Imago stouter than the *Spilarctia* (confined to the Old World). Whereas the palearctic species are throughout white or cream-coloured, there occur in America also grey *Spilosoma* which, however, deviate from the typical species also in other respects. See Vol. II, p. 87. Only 5 species in America.

S. virginica F. (39 b). Typical specimens are unicolorously white, only rarely some small dark scales *virginica*. may be discovered by means of the lens. — **fumosa** (39 c), however, are according to H. Strecker specimens *fumosa*. in which greyish shades extend from the apex of the wing sometimes far into the forewing; mostly only the apical margin is slightly sooty greyish. — Larva black, with black or also fox-coloured hair, the articular indentations white. Head black. — The species is distributed through the whole of the United States from Nova Scotia to Vancouver and extends to the north as far as Canada, to the south as far as Mexico; the butterfly is everywhere common, coming to the lamp on some evenings in great numbers; the larva may easily be bred with lettuce, Plantago, or lion's tooth. The species is not to be confounded with the likewise white species *Maenas vestalis*, *Estigmene congrua* and the following species.

S. latipennis Stretch (39 e) is likewise white, but of a somewhat more transparent and purer snow- *latipennis*. white, whereas *virginica* is coloured more milky white. Anterior femora and hips rosy-red. — Larva velvety-brown, densely haired black, with white stigmata. Head yellowish-brown, above darker. Atlantic States; much less distributed and rarer than the preceding species.

S. rubra Neum. (39 c). ♂ grey, tinged rosy; forewings sometimes with a dark median band; costal *rubra*. margin, head, and thorax of a bright red, hindwings with yellow hair and fringes. Forewings broad, of a bright yellowish-brown, hindwings grey, mostly with a broad red margin. — In **walsinghami** Btlr. the ground-colour *walsinghami*. is a bright vermilion. — In **danbyi** Neum. the thorax and forewings are dark brown, less tinged rosy, so that *danbyi*. the animal somewhat recalls a dark *Phragmatobia rubricosa*. In this British Columbian form the antennal shaft of the ♂ is red, the pinnae are black. — Western parts of the United States, from British Columbia to California, but in many districts rare.

S. kasloa Dyar, denominated by the habitat Kaslo (Brit. Columbia) resembles the following species; *kasloa*. thorax and forewings in the ♂ from dark to purple brown, the cell-end and postmedian band indicated by dark scales; hindwings black, veins and fringes reddish. ♀ carmine, forewings scarcely marked, hindwings almost entirely, or in the marginal area black.

S. vagans Bsd. (= pteridis H.-Edw., bicolor Wkr.) (39 c). The ♂ has ochreous-yellow forewings, *vagans*. sometimes with faintly darker markings, the hindwings being either grey, except the yellow distal margin, or yellow with grey markings. The ♀ resembles that of *rubra*, but it is more one-coloured and darker, not so bright red. — In the form **rufula** Bsd. (= punctata Pack., proba H. Edw.) also the ♂ has yellowish-brown, *rufula*. instead of loam-coloured, forewings. Out West, from Washington (Terr.) to California. The yellow form is common, the red one being rarer.

Genus: **Maenas** Hbn.

Already on p. 237 in Vol. X, when dealing with the Indo-Australian *Maenas*, we have stated that most of the Americans which HAMPSON included in this genus, were here separated as a genus of its own (whilst there it was denominated *Borseba* Wkr.). In fact there are but few American species that may remain in this genus characterized in Vol. X, p. 237. Certainly, if we exclusively judge from the venation of the wings, we may be easily induced to combine the species mentioned here with the quite differently organized *Palustra*, *Borseba*, and perhaps even with certain *Antarctia*. We enumerate here only the white, light green, and some speckled, mostly unicolorous species which, having of late been mostly described by ROTHSCHILD, are reckoned to the *Diacrisia* (in the broader sense) by their author and by HAMPSON.

a) White species.

- vestalis*. **M. vestalis** Pack. (39 c) is entirely white, like a white *Spilosoma*, the anterior femora above rosy-red, but the abdomen in typical specimens banded black, in the form **amelaina** Dyar (39 c) there are traces of blackish markings or they may be absent; but in that case always to be recognized by single, small black dots on both wings. Mostly the small dark dots on the veins form antemedian and postmedian rows on the forewing. Also in the middle of the hindwing at least 1 black dot, whereby the species can be discerned from the otherwise similar *Estigmene congrua*. This species also only occurs in the western parts of the United States.
- jussienae*. **M. jussienae** Poey (39 d) is entirely white like a *vestalis amelaina*, but only half its size. Only at the cell-end of the forewing a small black dot. Cuba.
- pelopea*. **M. pelopea** Drc. (39 d) is white with a yellow head and abdomen. The veins of the forewing fine though distinctly black. Mexico.

b) Green species.

- aeruginosa*. **M. aeruginosa** Fldr. (39 d). Pale light green, the hindwings lighter, the abdomen above spotted darker. In the lower cell-angle of the forewing there is often a small black dot. Colombia, in December in Bogotá and its environs.
- underwoodi*. **M. underwoodi** Rothsch. Thorax and forewings apple-green, the latter speckled brown, with a dark postmedian band. Hindwings pale apple-green, with a brown inner-angular spot; abdomen brick-red. Costa Rica.
- ockendeni*. **M. ockendeni** Rothsch. Body above turquoise-blue, forewings of a Veronese green, hindwings semi-diaphanous light whitish-green. South East Peru; based upon 1 single ♀ with very convex margins of the wings.
- aldaba*. **M. aldaba** Dogn. Like the preceding, quite pale green, but the forewing with a scarlet costa, a small black spot at the lower cell-angle, and a black, dentate postmedian line, being strongly angled in the two folds, 30 mm. Loja (Ecuador).
- viridis*. **M. viridis** Dogn. is another green species from South Peru. It has an expanse of 37 mm, being quite green, but the forewing of a deeper green with two irregular, black transverse lines; the proximal one at the median angled, the distal one, behind the cell, sending truncate teeth over 3, 4 and 5. Besides the forewing has a red costal margin and a small black spot near the base. Hindwing with a small dot in the cell, and a postmedian curved line.
- lymphasea*. **M. lymphasea** Dogn. Described as *Phragmatobia*, placed to *Diacrisia* by HAMPSON. Green, hindwings very much lighter than the forewings. The latter with a pink costal margin. Abdomen likewise pink. Ecuador; Loja.
- irrorata*. **M. irrorata** Rothsch. (39 f). Forewings light green, but so densely speckled brown that the ground-colour almost disappears, in the basal half there is a brown X, at the cell-end a chocolate spot. Hindwings greenish white. Huancabamba (Peru). The species in its structure deviates so much from the other species of the genus that HAMPSON established for it the genus *Chlorocrisia*.

c) Species with a yellow ground-colour.

- intricata*. **M. intricata** Wkr. (39 d). Dull milky-white forewings with bands of brown streaks, at the base, through the middle and at the margin, alternating with fine rows of dots. At the cell-end of all the wings a yellowish-brown shade. South Brazil, near Rio, Santos etc.
- alcumena*. **M. alcumena** Berg from Argentina is larger, of a purer white, marked darker brown, at the cell-end of the forewing a small orange spot bordered with black. Is reported to occur together with *intricata*, without any transitions, for which reason it is probably a distinct species. — In **steinbachi** Rothsch. (39 d) the median band composed of stripes is replaced by a brown homogeneous band; from East Bolivia. — **flavitincta** Rothsch. from Venezuela has the streak-bands through the forewing greatly reduced. — **kennedyi** Rothsch. from Minas Geraes has the hindwing more intensely tinged yellow in the proximal half. — On the whole, the species is distributed very far, and very common, the butterflies coming particularly often to the lamp.
- pulvcrea*. **M. pulvcrea** Hmps. (42 i), from Paraguay (Sapucay) and North Argentina, has an orange head and thorax, and dark blackish-brown palpi, forehead, antennae, tibiae, and tarsi. Abdomen orange, above and laterally rows of black punctiform spots. Forewings orange-yellow, finely dusted brownish; hindwings likewise orange. 36 to 40 mm.

d) Species with hyaline wings.

- hyalina*. **M. hyalina** sp. nov. (42 h). This species, according to its nature, would have to be inserted in the large genus *Diacrisia* in HAMPSON's sense, which, however, comprises rather heterogeneous elements, and it is possible that the form has already been described by another genus. All the wings, except the costal and inner-marginal areas, purely hyaline, the yellow costal stripe with 3 black spots, the brownish inner-marginal area with 2 median streaks. Abdomen orange-yellow, the middle rings black. FASSL brought it from Colombia.

2. Genus: **Isia** Wkr.

The only species of this genus being better known by the name of *Pyrrharcia* Pack. is a very robust butterfly somewhat recalling the European *Spilarctia lubricipeda* L. (*lutea* auct.) by its colouring and marking. The larva, however, deviates so much that the imago emerging from it, exhibiting besides more pointed wings, cannot be regarded as a *Spilosoma* or *Diacrisia*. The larva has on each of the 6th to 9th segments a dorsal brush, being otherwise peculiar of the *Dasychira*- or *Orgyia*-larvae, and on the 12th segment the dorsal hairs are prolonged.

I. isabella Sm. & Abb. (= *californica* Pack.) (39 d). Thorax and forewings *isabella*.
yolk-coloured; hindwings in the ♂ lighter, in the ♀ in the distal part more reddish-yellow; abdomen reddish-yellow. Forewing often with small black dots and a loam-coloured shade, strewn either more sparsely or more densely. — Egg hemispherically, white, with a polygonical network noticeable only under the microscope. Larva anteriorly and posteriorly black, the 4 middle segments above haired more rusty-brown, each with a dense hair-brush on the dorsum. At the sides, above the stigmata, a light stripe, being broadly interrupted on each ring-indentation. On trees (cherry, oak) as well as on numerous low plants (*Plantago*, *Solidago*, *Chenopodium*, *Compositae* etc.). The authors figure the larvae on *Elephantopus scaber*. Pupa yellowish-brown, in a felt-like web. Everywhere in the United States, in the east and west, from Canada to Texas, in summer common; the larva is particularly common in autumn, before hibernating, running across the roads.

3. Genus: **Estigmene** Hbn. (*Leucarcia* Pack.)

This genus founded upon an Arctiid common in North America, comprises to-day about 30 species of a universal range. From the very closely allied genus *Phissama* (Vol. II, p. 90, *Cretonotus*, Vol. X, p. 252) it differs by the marks mentioned there. The thorax is so densely and uniformly haired, that in undamaged specimens neither the collar nor the shoulder-covers are particularly prominent. As far as they are known, the larvae seem also to be more finely haired. The genus is somewhat allied to the palearctic *Diaphora*.

E. congrua Wkr. (39 e). ♀ very similar to the palearctic *Diaphora mendica* (Vol. II, t. 17 b), but *congrua*.
often without any small black dots at all, or with but one at the cell-end of the forewing; ♂ likewise entirely white, not grey as in *mendica*. Abdomen in both sexes snow-white — In **antigone** Streck. (39 e) the forewings *antigone*.
are more copiously dotted dark; — **athena** Streck. has a black instead of white antennal shaft, and **prima** Slosson *athena*.
(39 e), presumably a distinct species, having beside numerous small spots on the forewings also small dorsal *prima*.
spots on the (yellow) abdomen. — Larva light grey with dark tubercles with bristly hair; the hair on the sides long; head of the young larva with 2 dark dots, later on black. On low plants. — In the eastern parts of the United States, to the west as far as the Rocky Mountains. In the north (New England, Canada) the form *prima* is rare, in the south where the form *antigone* occurs, it is common in some parts.

E. acraea Drury (= *caprotina* Drury, *pseuderminea* Peck, *menthastrina* Mart., *californica* Pack., *acraea*.
packardii Schaupp) (39 e). Larger than the preceding, snow-white with small, fine, black, distinct spots and an orange-yellow abdomen spotted black, the ♂ with yolk-coloured hindwings, beneath quite yellow; but in the form **mexicana** Wkr. (39 e) also the ♂ hindwings and under surface are white. — **arizonensis** Rothsch. is like *mexicana*.
mexicana, but much more copiously and densely spotted black. — From the latter, **columbiana** Rothsch. from *ariconensis*.
Colombia differs by the ♀ exhibiting only yet 2, the ♂ only few black spots at the margin and cell-end. — **alba** *columbiana*.
Rothsch. (39 e) from Central America is quite snow-white. — In **klagesi** Ehrh. (39 f) the black spots of the *klagesi*.
forewings have disappeared except faint traces. — **dubia** Wkr. (= *rickseckeri* Behr) shows sooty brownish *dubia*.
body and wings. — Larva, when young, flesh-coloured, later on over the dorsum yellowish-brown with tufts of brownish bristles standing on the dorsum on dark tubercles, on the sides on reddish ones. Head lustrous black with yellow sutures. In the south particularly on rattlebox (*Crotalaria*) and other Papilionaceae, in the north common on *Plantago* and also many other low plants. The larva grows very stout. Pupa lustrous earth-coloured. Canada to Colombia.

4. Genus: **Euchaetias** Lyman (*Euchaetes* auct.)

Hereto belong about 15 species, slender, rather small butterflies with long forewings and short bodies, the ♀♀ sometimes with anal wool. Proboscis absent, antennae doubly combed, the pinnae in the ♂ not long; palpi short, rising obliquely; forewings without an accessory cell; the 1st subcostal vein rises immediately behind the middle of the cell, the 2nd before its end; discocellular of both wings slightly bent in, but not sharply angled as in *Chloroda*. The genus is exclusively American.

E. oregonensis Stretch (39 e). Dull white, with a yellowish-grey hue over it. Head, anterior thorax *oregonensis*.
and abdomen yolk-coloured; the latter has black dots on the dorsum and sides. — Larva pale yellow, with light slate-coloured hair, that are particularly long at the anus. Canada and northern parts of the United States,

particularly common in the west; the larva living on *Apocynum androsaemifolium* runs very quickly round on the roads; the butterfly is fond of coming to the light.

- pudens.* **E. pudens** *H. Edw.* (39 f). Smaller, dirty white with a yellow ring round the neck, the forewings with a greyish-yellow hue on them, and a series of black dots across the abdomen. ♀ of a purer white. Texas.
- egle.* **E. egle** *Drury* (= *cyclica* *H. Edw.*) (39 f). Dirty yellowish-grey, abdomen dull yolk-coloured, with black dorsal dots, beneath and behind white. Eastern parts of the United States; common. — Larva on *Asclepias*.
- epagoga.* **E. epagoga** *Dyar* (39 f). Unicolorously slate-grey, similar to *egle*, but of a purer, not yellow tinge, and the abdomen of a beautiful rosy red, like in the smaller *murina*, with black dots over the dorsum. Mexico; rarer. The figured ♂ (Coll. DRAUDT) from Tehuacan, taken in September.
- mitis.* **E. mitis** *Schs.* (39 f) is very closely allied to *epagoga*, but the ♂ hindwings are almost purely white, the ♀ has thick, yolk-coloured anal wool. Costa Rica; the figured ♀ from the Volcano Irazu.
- expressa.* **E. expressa** *H. Edw.* (39 g). Thorax and wings dark brown, abdomen dark pink with dorsal punctiform spots. Arizona and Mexico. Perhaps only the northern form of the preceding, since specimens from Mexico are reported to be of a lighter grey.
- bolteri.* **E. bolteri** *Stretch* (= *scepsiformis* *Graef*) (39 f). Forewings and thorax chalky white, hindwings in the ♀ dark brown, abdomen bright light red. Texas, not common.
- psara.* **E. psara** *Dyar* from Mexico has the size and shape of *bolteri* and resembles otherwise *epagoga*, but the wings are of a darker grey, and the abdomen is black to close in front of the red end, and exhibits in the ♂ a peculiar blue reflection, by which the species is at once recognizable. Rare.
- murina.* **E. murina** *Stretch* (39 g) is smaller than the preceding, of a dirty greyish-brown, hindwings lighter. Abdomen dull miniate, changing to orange-red, with black dorsal spots. Texas, rarer.
- perlevis.* **E. perlevis** *Grt.* (39 g). greatly resembles *murina*, but the abdomen and the inner-marginal area of the hindwing near the abdomen purple-red. Arizona.
- albicosta.* **E. albicosta** *Wkr.* (= *fumidus* *H. Edw.*) (39 g). ♂ blackish-brown with a hemochrome abdomen dotted black and a diaphanous diffuse patch in the hindwing. The ♀ is much larger and has a broad, whitish costal stripe. The ♂ has only whitish-yellow spots on the shoulders, whilst the costal stripe is absent. Thus it greatly resembles (superficially) *Scepsis fulvicollis* (26 a) or *wrighti* (26 b), which has effected the denomination of allied species (*scepsiformis* *Graef*.)
- antica.* **E. antica** *Wkr.* (= *zonalis* *Grt.*, *parazona* *Dyar*) (39 g) entirely resembles the ♀♀ of the preceding species, but the abdomen is above banded red, not dotted. Arizona, Mexico, and Central America; apparently rare.
- gigantea.* **E. gigantea** *Bs. & McD.* is larger than *egle* (39 f) and has a scarlet abdomen on the dorsum of which there is a series of black spots. Also the anterior margin of the collar is red; behind this red margin of the collar an ochreous line. Thorax and forewings brownish-grey, the latter in the marginal quarter speckled lighter. Arizona. Presumably closely allied to *epagoga* and *mitis*. 42 mm.
- rizoma.* **E. rizoma** *Schs.* (39 g). One of the largest species. Dark brown, sides of the neck, margins of the shoulder-covers, a curved longitudinal stripe through the middle of the forewing and small submarginal spots of the hindwing white. Abdomen red with black transverse stripes which are connected by a longitudinal stripe across the dorsum. Brazil: Castro (Paraná).
- castalla.* **E. castalla** *Bs. & McD.* Thorax and wings white, forewings with a grey cell-end spot; abdomen red with black punctiform spots on the dorsum and sides. Arizona. Similar to *Pyg. elegans*, but the anterior tibiae not with spurs.

5. Genus: **Pygarcia** *Hrt.*

Proboscis absent, palpi short, porrect, ♂ antennae with very short double combs. Tibiae with short spurs. Venation like in *Chloroda*, but the two veins petioled there in the hindwing run separately like in *Euchaetias*, to which the genus is closely allied.

- elegans.* **P. elegans** *Stretch*. Snow-white, chest and abdomen purple red. California, Arizona, New Mexico.
- roseicapitis.* — In the form **roseicapitis** *Neum. & Dyar* (39 g) from Mexico to Guatemala the head is also purple red. Rather rare.
- vivida.* **P. vivida** *Grt.* (39 h). Abdomen and hindwings similar to *elegans*, but the forewings dirty yellowish-grey with a yolk-coloured longitudinal stripe at the costa and proximal margin. Texas; rare.
- fusca.* **P. fusca** *Rothsch.* (39 h) from Arizona and Costa Rica, has unicolorously chestnut-brown forewings without a paler costal margin; otherwise like the preceding.

P. spraguei Grt. (= *eonspicua* Neum.) (39 h). Earth-grey, with a dark yellow longitudinal stripe *spraguei*. at the costal and proximal margins of the forewing; abdomen red. Georgia, Kansas, Colorado. Not common. The figured example was taken in July.

P. abdominalis Grt. (39 h) entirely resembles *spraguei*, but the abdomen is yolk-coloured instead *abdominalis*. of red. Florida; rare.

P. oslari Roths. from New Mexico has the size and shape of the preceding, but the abdomen is salmon- *oslari*. coloured, and the wings are unicolorously dull greyish-cream-coloured, without the prominently white costal and proximal margins by which *abdominalis* is characterized.

6. Genus: **Palaeomolis** Hmps.

The genus is easily recognized by the relatively short, broad forewings and the large hindwings. Antennae rather long, quite short-combed, palpi long, extended straight forward. Head and thorax with long and dense hair, the abdomen but little projecting beyond the anal angle.

P. garleppi Roths. (39 h) is the smallest species; through the dull ochreous-yellow forewing 3 *garleppi*. oblique, black transverse streaks which are distally convex below the costa. At the cell-end a black, comma-like spot. Hindwings lighter with a dull cell-end luna. Under surface pale ochreous-yellow, the forewing with a reddish-yellow costal stripe, all the wings with a dark cell-end luna. From Bolivia from the Rio Songo.

P. hampsoni Roths. (39 h) entirely resembles *garleppi*, but the ground-colour is a dirty yellowish- *hampsoni*. brown, and on the very broad forewing there are only traces of the black transverse streaks and cell-end spots. South East Peru.

P. purpurascens Hmps. (39 h) is larger and more slender than the preceding, in the colouring and *purpurascens*. marking quite similar to *garleppi*; the 3 transverse lines are distinct, but the cell-end lunae are absent.

P. metacauta Dogn. Thorax and head brown, with a black forehead, abdomen and under surface *metacauta*. of the body reddish-yellow; Forewings brown, watered with darker atoms. Costa and veins in some places tinged red-yellow, with a small black discal dot, a transverse line anteriorly, one in the middle and one beyond the middle, starting from costal shades and running almost parallel, being distally angled and extending obliquely to the proximal margin. Hindwings reddish-yellow. 29 to 32 mm. Colombia.

7. Genus: **Hypomolis** Hmps.

Proboscis stunted; the palpi much shorter than in *Palaeomolis garleppi*, hidden, like the eyes, too, in the shaggy hairing of the head. The posterior tibiae are without the middle spurs, the terminal spurs being strong. On the forewing the 1st subcostal vein rises far, the 2nd directly before the upper cell-angle; the cell itself is long, the discocellular almost precisely rectangular. On the hindwing veins 3 and 4 rise from the lower cell-angle, 5 being absent. Eight species are known, some of which are very much alike.

H. palmeri Roths. (39 h). Thorax and vertex brown, chest and head anteriorly with the palpi of *palmeri*. a bright red, abdomen dark pink. The forewings still strongly recall the *Palaeomolis*-species, being dirty greyish-green, thinly scaled, with a red costa and blackish marks before the apex, in the middle of the costa and above the proximal margin; hindwings diaphanous yellowish-rosy. West Colombia, taken in December at an altitude of almost 6000 ft.

H. rubricosta Dogn. entirely resembles the preceding, but the chest is more ochreous instead of scarlet. *rubricosta*. The forewings ochreous, slightly tinged brownish, above the proximal margin not so distinctly marked dark as in *palmeri*. Hindwings ochreous. Ecuador.

H. testacea Roths. (39 i). Quite thinly scaled, yellowish-brown, the forewings with darker yellowish- *testacea*. brown veins, a costal shade in and beyond the middle, from the latter a partly obsolete nebulous stripe behind the middle of the proximal margin, above which the submedian fold is shaded darker. Hindwings tinged dull greyish-brown, in the inner-marginal area more yellow. Abdomen ochreous. The species strongly recalls the form described by ROTHSCILD as *Automolis turupianoides* which may also belong hereto. Peru.

H. metarhoda Dogn. Forehead rosy. Thorax greenish ochreous, densely haired. The shoulder-covers *metarhoda*. bordered with reddish bristles. Abdomen reddish-yellow. Forewings creamy-white, towards the margin tinged greenish, on the proximal half a moss-green spot; costa red-yellow with 3 dark dots from which the following transverse lines proceed: a strongly angled line before the middle, a curved line in and one beyond the middle. Under surface pale orange-red with 3 small bows. Hindwings on both surfaces orange-red with yellow fringes. 31 mm. Closely allied to *palmeri* (39 i) and *rubricosta*.

H. fassli Roths. (42 f). ♂ chest, head, antennae and legs, as well as thorax and abdomen dirty brown. *fassli*. Wings hyaline, margins and veins dirty blackish-brown. Length of forewings: 17 mm. From the Monte Tolima in Colombia, taken by A. H. FASSL at an altitude of 3200 m.

- rothschildi*. **H. rothschildi** Dogn. Head and thorax olive, the former with a red spot in front, thorax posteriorly red-haired, abdomen rosy-red. Forewings pale olive strewn with some darker olive atoms, costa red; cell-end and the veins of the distal half partly red. 3 black transverse lines, an antemedian being angled on the median, a middle line being doubly angled, and a postmedian line. Hindwings whitish olive, costa, a part of the cell, apical region and margin rosy-red. Cali in Colombia, discovered by FASSL. 34 mm.
- minca*. **H. minca** Schs. 30 mm. Black; forewings greyish-black, the hindwings with a dark blue reflection. On the forewing vein 7 and 8 are coalescent; otherwise the venation is said not to differ from that of the other *Hypomolis*. From Oaxaca (Mexico).
- lithosiaphila*. **H. lithosiaphila** Dyar (39 l). 26 mm. Black, forewings with a blue reflection. A large orange spot at the base, reaching neither the costa nor the proximal margin, its distal edge oblique. Hindwings with an elliptic spot at the basal half of the costa. Underside similarly coloured. Discovered by ROBERT MÜLLER near Tehuacan in Mexico.
- evippus*. **H. evippus** Drc. (39 i). Quite light green, the forewings thinly scaled, diaphanous with a golden-yellow costa and similar fringes. Hindwings diaphanous greenish-white. Chest and forelegs golden-yellow, under surface of wings whitish. Bolivia.

8. Genus: **Chloroda** Hmps.

In the structure similar to the preceding genera, but without the shaggy hairing of the body. Proboscis present, though small; antennae of half the length of the costa; the forewings more pointed, the hindwings of the ♀ of a bright salmon-colour. The forewings are of a conspicuous colouring. Only one, rather rare species was known; another one discovered by FASSL seems to belong to it.

- rufoviridis*. **Ch. rufoviridis** Wkr. (= *thoracica* Rothsch.) (39 i). The apple-green forewings have at the costal and proximal margins 2 distinctly black comma-like streaks each. Hindwings of the ♀ deep rosy-red, in the ♂ lighter, yellowish or even hyaline light green; shoulder-covers margined pink. Colombia to Bolivia and Peru. Of a very variable size.
- rufolivacea*. **Ch. rufolivacea** spec. nov. (39 l) has the size and shape of the preceding; forewings olive with small black costal spots and 3 convergent lines from the middle of the wing to the middle of the proximal margin, the proximal one of which turns before the proximal margin towards the base; hindwings salmon-coloured, like the abdomen. Colombia.

9. Genus: **Turuptiana**.

Proboscis present, though very small and thin; imago mostly white or yellow, of the shape of *Enerythra*, but with very short palpi. In the venation different from *Enerythra* by the 2nd subcostal vein branching off before the cell-end, not being petioled with the others, and running parallel to the 1st. HAMPSON adds to the mostly rather similar species the greatly deviating *Chaetoloma dissimilis* Schs. resembling in its exterior *Agaposoma marcescens*; a *Heterocera* not yet classified from Colombia, which ROTHSCHILD has provisionally placed to *Antiotricha* (s. p. 298), the venation of which, however, is not quite distinct in the only figure existing.

- obliqua*. **T. obliqua** Wkr. (= *ochrosteria* Fldr., perfecta H. Edw.) (39 i). White with a yellow dorsum and abdomen in the ♀, the anterior part of which is above black. On the forewing, along the costa and proximal margin, one brown band each, both connected by a somewhat curved oblique stripe; thus a resemblance is effected to a *Robinsonia grotei*. Mexico, not rare; the figured specimen originates from Costa Rica. To the south the species goes as far as Colombia and Ecuador. — **affinis** Rothsch. from Venezuela and Peru seems to differ chiefly by the hindwing being tinged yellowish-grey at the proximal margin, whereas in *obliqua* there is a large grey cloud at the anal angle. The distal margin of the forewing is in Mexico-specimens mostly entirely white, otherwise usually bordered with blackish.
- lacipecta*. **T. lacipecta** Drc. (39 l). Size of the preceding, but the ♀ sometimes larger. Similar to *obliqua*, white, in the ♂ the dark costal stripe of the forewing is absent, and the oblique stripe does not reach the costal margin; in the ♀ the forewing is all white. Central America (Guatemala).
- permaculata*. **T. permaculata** Pack. (= *caeca* Streck.) (39 i). White, thorax and forewings covered all over with numerous thick black dots; abdomen above black, the hindwings with few dark spots before the margin and at the cell-end. The spots of the forewing form series which may sometimes flow together; sometimes, however, the black spots are also reduced (= ab. **reducta** Grt.). From Arizona to California. This species shows relations to *andromela* Dyar having been described as *Ecpanttheria*, and it has even also been described as *Ecpanttheria caeca* by HRRM. STRECKER and compared with *Ecp. scribbonia*.

T. tenebra Schs. (39 i). Size and shape of *permaculata*, but the black spots of the forewings sometimes *tenebra*. flow together forming irregular clouds, particularly at the proximal margin, costal margin, and in the marginal third; the hindwing is blackish, except a lighter central diffuse patch. Mexico.

T. nemophila H.-Schäff. (39 k) has olive forewings, marked creamy-white only at the costa and *nemophila*. in the marginal area, with blackish-brown costal triangles, curved transverse lines, and subterminal ellipses crossed by light veins. The ♂ hindwings yolk-coloured with black bands, those of the ♀ blackish, except the broad yellow distal margin, and clouded yellowish. Abdominal dorsum in the posterior half black. Central America, Venezuela. — **pratincta** form. nov. (39 k) differs by the ♂ forewings exhibiting much more creamy-white parts, *pratincta*. the hindwings being scarcely spotted. In the ♀ all the markings are of a more distinct and deeper tinge, the hindwings exhibiting bright yellow markings, the dorsum of the abdomen being black almost to the base. From the Rio Songo (Bolivia). — **obscura** Hmps. (39 k) has almost monotonous forewings, indistinct and less speckled *obscura*. markings, the hindwings being in the ♀ almost like the forewings. Peru and Ecuador.

T. bricenoi Rothsch., likewise from Venezuela, is paler and smaller than *nemophila*, all the dark *bricenoi*. markings smaller, the two curved central lines broadly interrupted. The hindwings are less spotted and extended at the anal angle.

T. neurophylla Wkr. (= *hebona* Dogn.). Very closely allied to **ockendeni** Rothsch. (39 k), but smaller, *neurophylla*. the forewings whiter, the olive-brown colour more diffusely distributed over the forewing, the subterminal, blackish-brown ovals thicker, the antemedian, angular line of which there are only remnants in *ockendeni* being *ockendeni*. distinct, thick and complete. In the ♂ the hindwings exhibit instead of the thick cell-end spot only dispersed black traces; the abdominal dorsum showing in *ockendeni* only a lustrous blue spot, is black in *neurophylla* except the sides of the base and the anal tuft. Venezuela, Colombia, Ecuador. *ockendeni* from Peru and Bolivia (Rio Songo).

T. tessellata Drc. Head and thorax black, vertex, collar and margin of tegulae yellow. Abdomen *tessellata*. yellow, the middle segments with black tufts. Forewings yellow, traversed from the costal margin to the proximal margin by 3 irregularly curved bands composed of large black spots; a black spot near the base. The veins almost white; fringes yellow. Hindwings pale yellow with a submarginal row of dark spots. 42 mm. Peru, taken at an altitude of 10 000 ft.

T. sanguinea Hmps. Black, femora above red, abdomen with subdorsal carmine bands not reaching *sanguinea*. the base. Forewings black, an irregular, curved carmine band extends from the costa to the base and reaches vein 1; an almost triangular band extends from the middle of the costa to vein 1, being on the veins incised by black stripes. A small postcellular spot; a curved postmedian band, and dull, dark streaks at the costa as far as vein 1. Apical part of the costa and fringes light yellowish, tinted carmine. Hindwings carmine, at the base black. Small lunae at the cell-end and a marginal band being narrowed to a dot on vein 1 are black. 28 mm. La Paz, Bolivia; 9000 ft.

T. sanguinipectus sp. nov. (39 i) from Bogotá strongly recalls the *Spilosoma aeruginosa* Fldr., but *sanguini-* it has a different shape of the wings, a much longer abdomen and purple chest; otherwise it is also quite apple- *pectus*. green with lighter hindwings, but at once discernible by the abdomen being above black, not green.

T. thursbyi Rothsch. (39 l) which is not before us and which we, therefore, copy from the Novit- *thursbyi*. tates Zoologicae (Vol. 18, VI, fig. 24), originates from Patagonia; it is, however, presumably rather a southern representative of the genus *Neoarctia*, than a *Turuptiana*. The forewings are nut-brown, crossed by lighter bands, hindwings carmine with a black marginal band. Abdomen red with a black dorsal stripe.

T. dissimilis Schs. (39 l). Thorax greyish-brown, head, collar, and shoulder-covers whitish; abdomen *dissimilis*. yolk-coloured, rings 4 to 6 blackish. Forewings yellowish-brown, at the margin darker, in front of it a light band; small ante- and postmedian black costal spots; from the middle of the forewing to the middle of the proximal margin a forked, black line. Hindwings yolk-coloured with small black clouds towards the anal angle. Larger than the preceding. Described according to 1 ♀ from Colombia.

10. Genus: **Euerythra** Harr.

Likewise without an active proboscis, but the palpi rather large, extended straight forward. The 2nd subcostal vein of the forewing emerges behind the cell-end and is petioled with the 3rd to 5th. Antennae of the ♂ doubly combed with rather long teeth. 2 white, rather small species, in which the abdomen is red above, from Texas and the neighbouring states.

E. trimaculata Sm. (39 d). White, the abdomen above red, and beginnings of brown bands near *trimaculata*. the base, before the apex and before the proximal angle of the forewing. Texas; the figured specimen from Colorado. Very rare.

phasma. **E. phasma** Harv. Like the preceding in size, shape and colouring, but the dark bands are complete, the posterior band extending from before the apex to beyond the middle of the proximal margin, and is connected with the basal one and with the middle of the distal margin by a horizontal branch running on the median. Texas; rare.

11 Genus: **Hyphantria** Harr.

These butterflies number among the best known noxious insects of North America. They are small insects, coloured or marked white, with entirely stunted proboscis and palpi. The 2nd subcostal vein of the forewing is petioled with the 3rd to 5th; the cell of the forewing long, the discocellular angled. 5 species are known, all from North America.

cunea. **H. cunea** Drury (= *budea* Hbn., *punctatissima* Sm. & Abb., *mutans* Wkr.) (40 a) is white, sometimes slightly sooty grey, the forewing with 4 to 7 rows of black dots, the hindwing with few small dots. Across the abdomen a chain of dorsal dots. — In *punctata* Fitch the spots of the forewing have disappeared except 1 or 2 at the cell-end and as many before the apex. — *pallida* Pack. (40 a) has on the wing small yellowish-grey spots instead of the black dots, and the row of dots on the abdomen is present. — *suffusa* and *brunnea* Streck. *candida*. are likewise denominations for brownish, instead of black, spotting. — In *candida* Wkr. there are small black dots only yet on the abdomen. — Larva across the dorsum blackish-brown, sides whitish-yellow with fine dark dots and small streaks, on the tubercles tufts of white hair. Particularly on mulberry, poplar, willow, and wild cherry; but generally on most various deciduous trees on which their large, conjoint nests are seen hanging causing very much harm in gardens, alleys and nursery-gardens. Pupa blackish-brown. — In the Atlantic parts of the United States, most anywhere from New York to the south as far as Texas; in the north of its range (e. g. in Massachusetts) only one generation, imagines in June, larva in August and September. In the south (Baltimore, Washington) the imago appears in May and again from the middle of July, larva in June and September: really great harm is only done by the autumnal generation, the larvae of which are said to be of a darker colour than the June specimens (RILEY). The eggs, being at first yellow, later on leaden-grey, are deposited in clusters, one ♀ often producing up to 500. Particularly great enemies are owlets (*Scops asio*), and *Prionidus cristatus*, which sucks the larvae.

textor. **H. textor** Harr. (40 a) looks exactly like a purely white specimen of *cunea* with which it is said to be identical according to different authors, differs, however, according to HOLLAND, by white antennae and the absence of the black dots on the dorsum of the abdomen.

orizaba. **H. orizaba** Drc. (40 a). The forewing is so much covered with blackish-brown spots and clouds, that the dark spotting outweighs the white ground-colour; hindwings spotted black, abdomen carmine-pink. Mexico.

penthetria. **H. penthetria** Dyar (40 a). Wings quite dark grey, only the veins of the forewing creamy-yellow. Mexico. Near Tehuacan, to be reached by rail both from Puebla and from Veracruz, apparently not rare in July.

aspersa. **H. aspersa** Grt. (40 a) is somewhat larger than the other species, dark greyish-brown, forewings with fine light veins and darker transverse bands. Abdomen vermilion with dark dorsal spots. New Mexico. — GROTE has established a genus of its own — *Alexicles* — for this species.

12. Genus: **Arachnis** Geyer.

Clumsy butterflies of medium size, with mostly dull colours, distinctly exhibiting, however, the Arctiid character both as imago and larva. Head deeply lowered, scarcely visible from above, without proboscis, palpi stunted, the 3rd joint quite rudimentary. Antennae in both sexes of a plain bristly shape. On the forewing the 2nd subcostal vein approaches the 1st, but does not touch it, so that a closed accessory cell is not formed. Thorax very stout, legs short and strong; abdomen towards the end in the ♀ very much swollen, always glaringly coloured. The larvae covered with dense bristly hair, on low plants, particularly Leguminosae. In *dilecta*, BARRETT observed a pungent smell, as penetrant as that of a wood-bug, though not so offensive. It is produced by thoracic secretions and adheres on the fingers for a long time. It is noticed in both sexes. — The 9 species of this genus are distributed from the southern parts of the United States to Central America.

aulaea. **A. aulaea** Geyer (= *incarnata* Wkr.) (40 b). Forewings greyish-brown, costal area and distal half with whitish-yellow spots and small bands defined by black, the cell beneath hemochrome. Hindwings on both surfaces dark brown with hemochrome bands. — Larva black, with a red dorsal line, the hair in the beginning anteriorly and posteriorly black, those on the middle segments rufous, in the grown-up animal all black, on brown tubercles; stigmata white; on low plants. — The red spotting of the butterfly may be greatly reduced. From Mexico to Guatemala. Common.

A. bituminosa Dyar (40 a, b). Wings without any red, unicolorously grey; in the ♀ the abdomen is *bituminosa*, above of a bright red with small black dorsal spots. Mexico. — It was considered to be an extreme form of the preceding, but the ♂ has more pointed wings, the ♀ a more obtuse body.

A. pompeia Drc. is almost exactly like *aulaea*, but the thorax is not marked grey, but unicolorously *pompeia*. dark brown, also on the wings the brownish-grey colour is increased, so that the forewings show much less white spots, the hindwings much less red spots. Mexico.

A. picta Pack. (40 b) was discovered by Bruce in West Colorado at an altitude of 6000 ft. Likewise *picta*. very similar to *aulaea*, but the white spotting of the forewings rather increased, hindwings with narrower and lighter dark bands. The under surface of the wings only pale pink or yellow, spotted light red, not dark red. — **citra** Neum. & Dyar (40 b) from Colorado shows the forewings spotted lighter. The hindwings without any black bands, quite pink or also (in the ♂) somewhat transparent. — In **hampsoni** Dyar the under surface of the basal area is red, spotted yellow at the costa; from New Mexico and Colorado. — In **perotensis** Schs. (40 b) from Mexico the brown colour of the forewing is increased, and the hindwing of the ♂ is quite transparent except faint spotting at the costa. — **maja** Ottolengui from Colorado, on the contrary, has the white spotting of the forewing increased and the ♂ has a hyaline patch in the cell of the hindwing. Larva on Lupinus. Colorado and California to Mexico; the typical form is common, *maja* and *citra* rarer.

A. dilecta Bsd. (= *sanguinea* Oberth.) (40 c). Forewings earth-coloured with large, irregular, white spots surrounded by black; on the under surface in the cell a red, longitudinal, diffuse spot. The ♀ has light red hindwings, in which the dark bands, only commenced at the costa in the ♂, extend through the whole wing as far as the proximal margin. Mexico, to the south as far as Honduras.

A. zuni Neum. (40 c) resembles *dilecta*, but the white spots of the forewing are smaller, those in the disc partly only in the shape of dots; hindwings in the ♂ semi-transparent, only the margins light red; in the ♀ with the 3 bands passing quite through.

A. martina Drc. (40 c). Forewings greyish-brown with sparse, light reddish-grey, small spots surrounded by dark, particularly at the costa and margin; hindwings in the middle transparent, the margins sooty brown. Abdomen red with a black dorsal stripe. Mexico.

A. mishma Drc. (40 c). Larger than *martina*; ♂ hindwings entirely transparent, forewings only in the distal halves. Abdomen red with a black dorsal stripe. Mexico.

A. albescens Hmps. (40 c). Dirty white, the spots almost extinct and only recognizable by the ring-like enclosures; abdomen yolk-coloured. Very much like some *Ecpantheria*. Guatemala. — **semiclara** Stretch is perhaps the normal ♀, perhaps also a form of *Ecpantheria*, allied to *suffusa*; it shows the forewing with 6 rows of dark spots on a whitish ground.

13. Genus: **Ecpantheria** Hbn.

Nearly all the species of this multiform genus have purely or dull white forewings marked with rows of dark rings, the hindwings of the ♂♂ sometimes extended like a tooth in the anal part, the abdomen being variegated (sometimes metallic). The shape is clumsy, the head of the ♀ sometimes lowered so much that it can scarcely be seen from above. Proboscis absent, palpi small, antennae in the ♂ so short-combed that they look like plain bristles. The larvae have coarse, dense, prickly hair; they are very stout, on being disturbed they roll together like most of the hairy earth-caterpillars do, and are fond of wet places (flooded meadows, water-ditches, pools etc.). About 40 forms are known, partly differing very much and having received more than 70 names. The range extends from Texas to Argentina, only one species (*E. deflorata*) goes as far as New England in the north. They all like to come to the lamp, whilst in day-time they are not easily discovered.

I. Forewings black with sparse white spots.

E. andromela Dyar (40 c). This species and the following are rather unlike the genus not only by their colouring and marking, but the ♂ is also without the tooth at the anal angle of the hindwing. They may not belong to the genus, but approximate the *Turuptiana*. Black, forewings with few white spots, hindwings quite blackish-grey. Thoracic dorsum black, only the shoulder-covers white; abdomen posteriorly golden yellow. Mexico.

E. atra Oberth. (40 c). The white spots of the forewings in the ♂ smaller, only that near the base of the wing larger. Thoracic dorsum white, abdomen only laterally yellow. ♀ white, the forewings densely spotted black, almost like in *Turuptiana permaculata* (39 i). — In the form **eminens** H. Edw. the forehead, thorax, and forewings are tinged yellow. — Mexico.

II. Forewings not black, with dark small spots or rings arranged in rows.

a) Ground-colour of the forewings greyish or brownish.

E. indecisa Wkr. (= *degenera* Wkr., *annulifascia* Wkr., *bonariensis* Bsd.) (40 d). Wings brownish light grey, so that the chains of spots and rings are noticeable only by their contours. Abdomen also grey, above

and laterally with golden yellow spots being confluent in the ♂. The figured specimens come from the district of Tucuman; ♂♂ from the environs of Buenos Ayres have a much lighter, almost chalky white ground-colour of the forewings. Common.

- albiscripta*. **E. albiscripta** Drc. (40 d). The rings and dentate markings of the forewings are white on a yellowish-grey ground. Hindwings in the ♂ white, in the ♀ greyish-brown with a white, undulate, postmedian marking. Body like in *indecisus*. South Brazil; Rio Grande do Sul.
- anomala*. **E. anomala** Burm. Pale olive, thorax marked white, abdomen laterally yellow, beneath white. Forewings with darker veins. At the costal margin and in the cell dull white and dark spots. Hindwings with white marginal dots, whitish streaks at the base of the costa, in and behind the cell. Somewhat larger than the preceding, Entre Rios (Argentina).
- suffusa*. **E. suffusa** Schs. (40 d). Size of the preceding; forewings quite light whitish-grey. Forewings with very dense chain-markings; hindwings white, in the ♂ with sparse black spots, in the ♀ with distorted rings filled up with grey. Abdomen golden yellow with black dorsal spots. — Larva grey, when grown up with a yellow head, with white striation and dark dotting, below the indistinct subdorsal line darker. Above the stigmata a broad, yellow lateral stripe; hair pointed and bristly, in dense tufts, on the first rings some long, white hairs. Mexico, common; the figured specimens from Misantla (♂) and Guerrero (♀).
- confusa*. **E. confusa** Drc. resembles *suffusa* in the colouring, size, shape, and marking, but the hindwings are less spotted, those of the ♀ in the basal halves all white, and the abdomen is above not spotted dark. Mexico.
- testacea*. **E. testacea** Roths. The species is easily discernible by the greyish-brown ground-colour covering the body and wings. Thorax with dark rings, abdomen blackish-blue, the base light yellowish-brown; forewings light cinnamon-coloured, with rows of dark rings, hindwings whitish, the inner-marginal area smoky brown. Peru.

b) Ground-colour of the wings purely white, only rarely with some yellowish tint.

1. Forewings traversed by rows of spots, not by rings.

- oblecta*. **E. oblecta** Dogn. is a very small species, based upon a ♂ of only 35 mm. Head and thorax brown, the latter above mixed with lighter hairs. Abdomen brown with yellow sides and white underside. Forewing with 5 transverse chains; the basal one extends to the submedian; the next has 1 costal spot and 3 dots between the median and the proximal margin. The middle chain, being doubled, composed of dissimilar internodal spots, followed by some smaller dots. The 4th, subterminal chain is likewise double; finally the terminal row. All the small spots are brown encircled by black. Fringes white. Tucuman (North Argentina).
- melanoleuca*. **E. melanoleuca** Roths. (41 a). Likewise small, the brown spots are much denser, so that they are confluent and form bands in the middle of the wing and at the margin of the forewing. Hindwings yellowish-white, almost unspotted. North Argentina (Santiago del Estero).
- magdalenae*. **E. magdalenae** Oberth. (40 d, e). Through the middle of the forewing a broad chain of spots, in the ♀ another one through the marginal third; between, as well as at the distal and costal margins small dark spots. Hindwings in the ♂ white, with a sooty black proximal margin, in the ♀ grey, the margin marked yellow. Colombia; the figured ♂ I obtained from Rio de Janeiro, where it was reported to have been captured. — **steinbachii** Roths. is larger, the proximal chain of spots of the forewing more remote from the base, so that the 3 bands of the forewing are closer together, the anal tooth of the ♂ longer; Bolivia.
- laeta*. **E. laeta** Wkr. (40 e) is very closely allied to *magdalenae*, but the forewing shows also in the ♂ 2 broad chains of spots, in the hindwings the whole inner-marginal half and besides the apex are sooty. The ♀ scarcely differs from the preceding species, but it shows the chains of spots somewhat torn, and on the dark hindwings mostly also light cell-end spots. — **praeclara** Oberth. (40 e) has diaphanous pale yellow ♂ hindwings with an ochreous tinge at the proximal margin. Venezuela and Colombia. — **braziliensis** Oberth. (40 e) has the ♂ hindwings diaphanous white, only the anal tooth being sooty, and the distal chain of spots of the forewing being composed of smaller spots. The author mentions „Brazil“ as its habitat; probably it is meant to the north of it.
- theophila*. **E. theophila** Dogn. has yellowish wings, the forewings being marked almost exactly like in *laeta*, the subterminal row of dots does not reach the border at the proximal angle. Hindwings with long yellow hair, 3 costal spots, and one small subcostal spot close before the apex. The ♀ has more white than yellow forewings, and the hindwings are almost quite black with a yellow subterminal line; at the margin some spots. A little larger than the preceding; from Popayan (Colombia).
- leucarctioides*. **E. leucarctioides** Grt. & R. (= *tenella* H. Edw.) (40 e). The chains of spots of the forewings much narrower than in *laeta*, and in the ♂ often entirely interrupted in the middle of the forewing. Hindwing at the proximal margin yellow, only the small apex of the anal tooth black. Mexico. — In the form **trebula** Drc. from Guatemala the forewings, particularly in the ♀, are intensely suffused with yellow.

E. ochreator *Fldr.* (40 f) is perhaps only an aberrative form of the ♀ of *trebula*; forewings more *ochreator*, densely and larger spotted black, but the hindwings golden yellow, with chains of black spots: I only know *FELDER*'s figure (*Novara*, t. 101, fig. 2).

E. cotyora *Drc.* (40 f) likewise greatly resembles *laeta*, but the ♂ has not the long tooth at the anal *cotyora*, part of the hindwing, which is neither sooty black at the proximal margin; in the ♀ also the hindwings are often intermixed with light spots. Costa Rica and Panama; numbers of it were taken by *FASSL* near Orosi, on the Volcano Irazu, in Costa Rica.

E. euripides *Dyar* is allied to *cotyora* (40 f), the markings are blacker, more angular and differently *euripides*, arranged, the hindwings yellow and the anal angle more pointedly extended. Thorax blackish-green, the patagia bordered with orange. Abdomen orange, on the dorsum 2 rows of small black spots. Forewings of a creamy colour, the spots jet-black. 50 mm. Mexico. Type in the National Museum of Washington.

E. extrema *Wkr.* (40 f). Rather small, the ♂ without the anal tooth of the hindwing. The forewing *extrema*, white with very numerous thick and fine dots; the antemedian and median rows sharply angular, those in the distal part of the wing irregular, sometimes confluent; hindwings whitish, the inner-marginal part and an antemarginal row of spots blackish. Mexico and Central America. — **chilensis** *Oberth.* is much larger, and the *chilensis*, median row consists of larger spots. According to *OBERTHÜR* from Chile.

E. quitensis *Oberth.* (40 f). A large, clumsy species with purely white forewings with roundish black *quitensis*, spots, the hindwings with sparse marginal spots, the thorax dotted black, and the dorsum of the abdomen metallic blue. — From Quito; according to *HAMPSON* a form of the widely distributed *deflorata*.

E. persola *Mschlr.* (41 c) from Jamaica has the purely white forewings scantily though distinctly *persola*, spotted blackish-blue. Abdomen and hindwings orange-yellow, spotted black, so that it somewhat resembles an *Estigm. acraea* (39 c).

2. Forewings white, intermixed with chains of dark rings.

E. deflorata *F.* (= *scribonia* *Stoll*, *oculatissima* *Sm. & Abb.*, *chryseis* *Oliv.*, *cunigunda* *Beauv.* nec *deflorata*, *Stoll*) (40 g). One of the large species, ♂ and ♀ forewings densely covered with large, thick black rings; hindwing with a black diffuse patch on the submedian fold and sparse marginal spots. Abdomen stout, above quite blackish-blue or with only scanty yellow spots on the abdomen and sides. — In ab. **confluens** *Oberth.* (40 g) *confluens*, the two middle rows of rings are flown together to one, thereby containing very long-stretched rings. — In ab. **denudata** *Sloss.* the hindwing is hyaline in the apical half. — Larva, when grown up, blackish-brown, with *denudata*, similar tubercles, and dense tufts of thick, stiff bristles of a blackish lustre. Head black with brown sutures. Before each segmental indentation a dark purple transverse band, of the same colour are the ventral feet and stigmata. It attains a length of 7 or 8 cm, being 12 mm thick. On *Plantago*, *Polymnia tetragonotheca*, *Ricinus communis*, and *Euphorbia cyathophora*, but also on numerous other low plants, on *Helianthus*, willows, according to reports also on cotton and coffee. It prefers particularly wet, sometimes flooded places; the butterflies are fond of the light, where they may sometimes be met with together with the ♂♂ of *Zeuzera pyrina* being of a somewhat similar exterior. From New York to the south through the eastern states as far as Texas and Mexico; in most of the habitats not rare.

E. ocellaria *F.* (= *cyaneator* *Wkr.*, *columbina* *Oberth.*) (40 g). Like the preceding with a black, *ocellaria*, lustrous blue dorsum of the abdomen, but the rings on the forewing larger and more regular, in the ♂ those in the marginal third obsolete; those in the ♀ are so large that they leave but very little space between. Hindwings in the ♀ half blackened. — In ab. **distans** *Oberth.* the ring-markings of the thorax have disappeared, *distans*, the wings are partly tinged brown. — Colombia.

E. robusta *Dogn.* Abdominal dorsum like in the preceding with a blue reflection, but with transverse *robusta*, golden bands on the middle segments; in the ♂ the apical half of the forewing is unmarked, hyaline like in *muzina*, but the former has a large orange spot on the greyish-brown abdominal dorsum exhibiting a faint small reflection. Ecuador: Loja.

E. dognini *Rothsch.* resembles *robusta*, but it is smaller, the ♂ with a white, not blackish-blue, *dognini*, chest; forehead and palpi brown, not blue; the thoracic spots grey, not white, as in *robusta*; and whereas in *robusta* the 1st abdominal ring is grey, spotted steel-blue, it is brown in *dognini*; the forewings of the ♂ are less hyaline and the hindwings not at all. Near Rio de Janeiro and in the Organ Mountains. Rare.

E. caudata *Wkr.* (= *mexicana* *Oberth.*) (40 h). Undoubtedly the southern representative of *deflorata*, *caudata*, the ring-markings sparser, finer and lighter, the markings on the thorax somewhat different (shoulder-covers with 2 rings each, instead of 1 ellipse). — **bolivar** *Oberth.* from Colombia has in the ♂ an almost quite golden *bolivar*, yellow abdomen with fine dark bands, and the markings of the forewing behind the cell have died away. Mexico to Costa Rica.

- cunigunda*. **E. cunigunda** Stoll (= ganglio Oberth.) (40 h). Very abundant ring-markings. On the thorax 4 ellipses, 2 more on the shoulder-covers, 5 rows of rings through the forewing and cell, the margins of the forewing densely covered with rings. Abdomen blackish-brown, with golden yellow bands. — In **cayennensis** the markings of the wings are duller, the abdomen is golden yellow with very narrow transverse bands being almost interrupted in the middle of the dorsum. — In **decipiens** Oberth. they are in fact interrupted and stunted to very fine, small stripes, the ring-markings are still duller, and in the ♂ extinct behind the cell. — From Guiana to South Brazil; not rare.
- heterogena*. **E. heterogena** Oberth. (= contexta Oberth., pellucida Schs.) (40 h). From the preceding distinguished by the thoracic marking consisting of parallel longitudinal lines, instead of rings. Distal half of the ♂ forewing unmarked, hyaline. Abdomen above blackish-blue. — **bahiensis** Oberth. (= boisduvali Oberth.) (40 h) is much smaller, in both sexes with abundant ring-markings (partly distorted), but easily discernible by the dark longitudinal lines of the thorax. — Brazil: Rio de Janeiro: *bahiensis* from Bahia.
- decora*. **E. decora** Wkr. (= cyaneicornis Grt., haitensis Oberth.) (40 h) is recognizable by the bright yellow abdomen being spotted white at the base and decorated with 2 parallel rows of blackish-blue transverse spots. Hindwing in the ♂ with a black spot in the anal tooth, in the ♀ with a subterminal row of rings. Mexico and the Antilles.
- cretacea*. **E. cretacea** Dogn. From the Eastern Cordilleras from Colombia (Medina) there is a species before me, particularly distinguished from *decora* by the 6 macular chains of the forewings being of a more uniform course, and by the yellow abdomen showing only on some segments black transverse bands of a blue reflection. As DOGNIN describes his *cretacea* from Medina, it may be it. But as he does not state whereby his *cretacea* differs from the other similar *Ecpantheria* and as his description is applicable for different species, this question cannot be decided here.
- bari*. **E. bari** Oberth. (40 i). A rather large form, recognizable by the thoracic marking, consisting of 2 crescents on the thoracic dorsum, touching each other with the convexities. Abdomen blackish-blue, scantily spotted yellow. In the typical form from Cayenne the rows of rings of the forewing are rather dense, and the hindwing has, beside an inner-marginal wedge, only some dispersed dark spots and rings. — In **orbiculata** Oberth. from Rio de Janeiro the rings at the margin of the forewing are somewhat expanded, and the spotting of the hindwing is somewhat denser, whereas in ab. **dubiosa** Oberth., likewise from Cayenne, the whole basal half of the hindwing is shaded with grey.
- abdominalis*. **E. abdominalis** Wkr. (= proxima Oberth.) (40 i). The abdomen being banded blue and yellow strongly recalls *decora*, the thoracic marking being similar, too. But the hindwing has a much shorter, obtuser anal tooth of the ♂, and not only in the tooth itself a black shade, but the latter extends as a long diffuse patch to the base of the wing, and the distorted ring-spots at the costa and margin of the forewing are not hollow, but filled up with blackish; from Brazil. — **detectiva** Oberth. (40 i) has in the ♂ forewing only very fine, small marginal dots, but an almost quite blue abdomen with but faint traces of yellow spots. — **detecta** Oberth. from Pará has likewise only marginal dots on the forewings and entirely white hindwings, but the costal rings of the male forewings are not filled up with dark, much rather those in the basal part and disc. — In **aramis** Oberth. (40 i), being probably the ♀ to it, all the rings of the forewings are filled up with a bright greyish-brown, and also the hindwings are abundantly spotted sooty-brown. Likewise described from Brazil (Minas-Geraes). — **annexa** Oberth. has a yellow abdomen with dark bluish-black bands, like the typical form, but all the rings of the forewings are filled up with white, and the hindwing has, beside a diffuse spot before the proximal margin, blackish spots along the anal half of the margin. — **kinkelini** Burm. (41 a) finally, denominated according to the Franefort paleontologist KINKELIN and considered to be a distinct species by OBERTHÜR and HAMPSON, differs but slightly from *aramis*; it has also the markings of the forewing filled up with grey, but the prothorax and the basal part of the forewing is sometimes slightly tinged rosy. All the forms of *abdominalis* originate from Brazil; *kinkelini* presumably also occurs in North Argentina, but scarcely in Buenos Ayres itself, as OBERTHÜR states.
- alpha*. **E. alpha** Oberth. (= orbiculata Drc. nec Oberth.) (40 i). This species greatly resembles the typical *abdominalis*, exhibiting the costal rings of the ♂ forewing also filled up blackish, and the long inner-marginal diffuse spot of the hindwing, but the abdomen is blackish-blue, very little spotted yellow, the rings of the forewings being somewhat differently arranged, and particularly the tooth of the hindwing much longer. Mexico.
- albicornis*. **E. albicornis** Grt. from Cuba is easily recognizable by the antennae being white above. Considerably smaller than *alpha*. Thorax above with brown rings, abdominal dorsum blackish-blue. The rings of the forewing are arranged in 6 rows, and rather small; the disc also in the ♂ not hyaline. Hindwings with some rings near the costa, otherwise few small black spots. Very rare, unless it be an insular aberration of another species.
- peruvensis*. **E. peruvensis** Hmps. (41 b). Taken by SIMONS in Peru at an altitude of 1200 ft., known to me only from HAMPSON's figure copied here, is larger than the preceding species and above all discernible by almost all the markings being extinct on the distal area of the forewing.
- muzina*. **E. muzina** Oberth. (41 a). ♂ wings hyaline in the whole distal areas, only at the base, costa and proximal margin sparse rings partly filled up with dark. The ♀ recalls a *heterogena*-♀ (40 b), but it has, instead of

a blackish-blue, a yolk-coloured abdomen spotted somewhat white. The species is almost everywhere in the hilly districts very common from Mexico to Venezuela, and the ♂♂ belong to the most common butterflies taken by the lamp. OBERTHÜR introduced a great number of denominations for this, somewhat variable species, all of which are cancelled by HAMPSON as being synonymous. *albicollis* shows the few rings filled up with white and the abdomen orange-yellow in the ♂ and ♀, with two lines of white spot; the thoracic dorsum has 6 dark rings, in *muzina* only 4, and besides the costa-rings are wider and square, in *muzina* small and round. „Brazil“. *thiemei* is only a small specimen, and *abscondens* the ♀ of it. — *depauperata* is a distinctly marked ♀ without the nebulous spots before the margin of the hindwing, and *garzoni* is, on the contrary, a particularly large specimen with bright colours and markings. — In *xanthonota* the costal and antemarginal rings are marked more thickly, and *yukatanensis* is the ♂ fitting to this ♀ form. — *sennettii* Lintner and a part of *eridane* mentioned by DRYCE in the Biol. of Central America likewise belong here, according to HAMPSON.

E. icasia Cr. (= *lautanae* F., *eridane* Hbn. nec Cr., *obliterata* Wkr., *simplex* Wkr.) (41 a, b) is very *icasia*. closely allied to the preceding, but in the ♂ the anal tooth is much shorter, in the ♀ the ring-marking quite pale, and in both sexes the thorax is snow-white, without any markings. From the West Indies, and on the continent from Surinam to Chile. — As **guadulpensis** OBERTHÜR figures a form from the Island of Guadeloupe, with much *guadulpen-* more abundant and distinct ring-markings, in which also the metathorax shows some small white ringlets, *sis*. whereas the collar and prothorax remain unmarked white. — **trinitatis** Rothsch. is the form from the Isle of *trinitatis*. Trinidad, in which the black of the abdominal dorsum is replaced by white transverse bands; besides the ♀ forewings show duller markings.

E. eridanus Cr. (41 b) from Colombia and Guiana is quite snow-white with an orange-yellow abdomen *eridanus*. banded white. Only ♂♂ seem to be known hitherto.

E. mus Oberth. (41 b). ♂ snow-white, forewings with very few small rings along the costa and proximal *mus*. margin, shoulder-covers with 1 ellipse each. Abdomen snow-white with 2 or 3 blue transverse bands before the end; in the ♀ the abdomen is above black with a white base. Forewings tinged yellowish-brown with rows of rings filled up with grey. Castro (Paraná), Brazil. — The form **brasiliensis** Rothsch. has mouse-coloured, *brasiliens-* instead of white ground-colour and distinctly marked ♂♂; it is also found near Rio and in Paraguay. *sis*.

E. kennedyi Rothsch. from Minas Geraes (Preto) in Brazil resembles the preceding, but it is larger. *kennedyi*. The chest is white, not black, and the palpi, being white in *mus*, are here black. Head and tegulae are grey instead of white; on the latter there are not 2 parallel dark lines, but they converge to a V. The costal area of the semi-transparent forewing is light grey, not white. Hindwings white. Described according to a ♂.

E. oslari Rothsch. (41 b) is the smallest species with chains of rings. The thoracic rings and those *oslari*. of the forewings very small, the chain very regular, the hindwing all white except a preapical costal spot, the abdomen yolk-coloured. From Brownsville in Texas.

E. nigriplaga Wkr. (= *obesa* Wkr.) (41 b). Large, particularly the ♀♀. The ♂ has a broad, large *nigriplaga*. anal lobe of the hindwing, and punctiform, filled rings; easily recognizable by the crimson abdomen showing black transverse bands. Jamaica.

E. burmeisteri Rothsch. (41 c) by the colouring and marking somewhat recalls the larger *kinkelini burmeisteri*. (41 a), but the abdomen is scarlet, with 2 rows of steel-blue dorsal spots; the anal segment above bluish-brown. The ♂ forewing in the disc hyaline. Thorax and wings smaller, and spotted brown not grey. JOSÉ STEINBACH brought it from Tucuman (North Argentina).

14. Genus: **Ectypia** Clem.

Without a developed proboscis; palpi minute, the 3rd joint stunted; head and thorax not woolly, but covered with smooth scales. Spurs of tibiae short. Only 2 almost white butterflies from North America compose this genus.

E. thona Streck. (39 l). We copy HAMPSON's figure which was copied from a figure by STRECKER. *thona*. White, with a very faint reddish-yellow hue; on the median and submedian, as well as at the costa and proximal margin dark streaks. Abdomen above yolk-coloured. New Mexico. Apparently very rare.

E. bivittata Clem. (= *nigroflava* Graef) is similar, all white, with thicker dark streaks often showing *bivittata*. knobs on the median and submedian, as well as on their branches before the margin. Little larger than the preceding. Texas. Likewise rare.

15. Genus: **Euverna** Neum. & Dyar.

Different from *Seiraretia* by the stunted proboscis, but otherwise similar to it in the venation, shape and habitus. More in the west of North America.

- clio.* **E. clio** Pack. (41 c). Purely white; median and submedian of the forewing distinctly black like the ends of the other veins of the forewing. Abdomen above yellow with a row of black punctiform spots. In the southern parts of the Rocky Mountains, in Arizona, Colorado, and South California, rare. — *jessica* is a form with blackened hindwings from the Glenwood Springs in Colorado, described by BARNES in the year 1900.
- mexicana.* **E. mexicana** Dogn. (41 c) is much smaller than *clio*, only the black ray on the median, and that above the proximal margin being distinct: there are hardly any traces to be noticed of the rays on the veins in the apical half of the forewing, and the marginal rays of the hindwings are absent altogether; the latter are snow-white. Mexico, rare.

16. Genus: **Seiraretia** Pack.

Only one conspicuous species; a white butterfly with dark veins, the larva being very variegated. From the preceding species it chiefly differs by the strong, active proboscis. The ♂ antennae are rather long-combed; the anterior tibiae have inside a short nail, outside a long nail. The species lives in the southern parts of the United States, being rather rare. Some African species, such as the cinnamon-coloured *S. jacksoni* Roths., which were brought into this genus, may be better inserted elsewhere.

- echo.* **S. echo** Sm. & Abb. (= *niobe* Streck.) (41 c). White, the veins bordered with an ochreous brown; abdomen above spotted black, in the ♀ tinged orange *). — Larva brown with tufts of golden yellow hair. Sides and venter golden yellow, head cerise. Across each segment a broad yellowish-red and a narrow whitish transverse stripe. On Sabal palmetto Lodd., that species of Chaemaerops-palms, from the filaments of which the „sombrosos“ are made. The butterfly is not common; it only occurs in the southern parts of the United States, in Florida, Alabama, Georgia, and Mississippi.

17. Genus: **Caridaretia** Hmps.

The genus was established in 1901 for an antarctic species characterized by its slender structure, narrow forewings, not large hindwings, and doubly combed antennae of the ♂. Proboscis stunted, the abdomen projects far beyond the anal angle. The two first subcostal veins rise separately, the footstalk of 3 to 5 emerges from the upper cell-angle.

- albicancellata.* **C. albicancellata** Burm. (42 b). Black, the forewings finely marked ochreous-yellow, the hindwings pink, the marking strongly recalling that of numerous *Noctuae*: the forewing shows an antemedian and a curved postmedian transverse line, a ring spot in the cell and a reniform spot behind the cell, as well as light yellowish veins. Hindwing with a rosy-red base and cell-end, and with a costally red, anally yellow postmedian line. From Argentina.

18. Genus: **Chlanidophora** Berg.

Likewise antarctic; the sole species differs from the preceding by its shorter, less extended abdomen, and by the 2nd subcostal vein anastomoses with the footstalk of the 3rd to 5th, forming an areola. Moreover, the forehead has in its middle a continuation in the shape of a truncate cone, and the ♂ antennae are plain. The type is in the Museum of Buenos Ayres.

- patagiata.* **Ch. patagiata** Berg by its marking recalls the preceding species, but it is considerably smaller (40 mm), the abdomen with orange bands, not as in *Caridaretia* only laterally marked yellow. The forewing has the whole proximal half white, with a pink tinge, so that only a distal band extending almost to the middle of the wing remains black, showing the veins light and besides a fine, light dentate line. Patagonia.

19. Genus: **Paracles** Wkr.

The palpi are longer than in the 2 preceding genera, but entirely hidden in the dense, coarse hair of the head. Proboscis stunted. The genus differs besides from the preceding by the antennae being combed in both sexes, by the absence of the accessory cell, and by only the 3rd and 4th subcostal vein having a joint footstalk.

- contraria.* **P. contraria** Wkr. (42 b) almost looks like a small, dark *Antarctia vulpina* (41 d). The orange-yellow abdomen is laterally black and has such a broad, black dorsal stripe that the yolk-coloured ground-colour is only yet contained in 2 narrow subdorsal stripes. Forewings like the thorax dark brown, with a creamy-white costal-marginal stripe; hindwings dull white, at the costa brown, at the proximal margin tinged yellow, Lower Amazon.

*) In the first figure by ABBOTT and SMITH, on account of the dusted stripes accompanying the veins of the forewing having been exaggerated, the exterior of this butterfly is so very much distorted, that HERM. STRECKER being familiar with these otherwise very well-done figures did not recognize the figure and once more minutely described the species in 1884 as a *Spilosoma niobe*; the latter was then enumerated by KIRBY, separated afar from *Seiraretia*, as *Estigmene* with a „?“.

20. Genus: *Mallocephala* Blch.

The butterflies corresponding with the palearctic *Ocnogyna* have an accessory cell in the forewing. The ♂ antennae are doubly combed with long branches and the ♂ abdomen is a very slim appendage disproportionate to the robust thorax, being somewhat conspicuous only owing to the long, dense, fleece-like hairing. The ♀ is very characteristic by a complete stunted growth of the wings. The palpi are just like in the *Antarctia* and *Palustra* lowered in the resting butterfly, their tips showing almost downward. Only few species resembling each other are known, the wings being unmarked. The larvae are covered with short and dense tufts of hair, with raised tubercles, living on low plants, numerous in the gardens of the towns, the male butterflies common on the lanterns in the streets.

M. deserticola Berg (41 d). In the ♂ the head, antennae, thorax, and forewings are of a light greyish-brown, hindwings and abdomen white, the former rarely with a darkened apex. The ♀ is quite yellowish-grey, the abdominal end broad white and woolly. Argentina, Patagonia, according to HAMPSON also from Colon. I captured both sexes in the town of Buenos Ayres itself, on the garden-walls, and found the cocoons underneath the covers of walls, in February. Not rare.

M. brittoni Rothsch. is very closely allied to the preceding. Head, body, and forewings of a brownish-creamy colour. Hindwings white. Antennae light brown. La Soledad in Argentina.

M. latior Btlr. (41 d). Dark ochreous-brown, hindwings dirty ochreous-white, abdomen of a brighter yellow with black dorsal transverse bands. ♀ yellowish-brown with similar stumps of wings and a white anal part of the abdomen. — Larva black with blue warts and red-brown, partly grey hair. Imago in February. Chile, common. — **tegulata** Btlr. is based upon 2 ♂♂ from Valparaiso, the wings being of a greyish chocolate colour instead of dark ochreous-brown, the hindwing at the base diaphanous. — **angustior** Btlr. has narrower forewings, and the ground-colour is bronze-brown. Likewise from Valparaiso. — ab. **obscura** Btlr. finally is a name given to an uncommonly dark specimen (♂). — The larva of *latior*, according to EDMONDS, is entirely *Arctia*-like.

M. magna Rothsch. (41 d). Thorax and forewings dark chestnut brown, hindwings whitish, head and abdomen above tinted orange. Salta in North Argentina.

M. peruviana Rothsch. (41 d) is somewhat smaller than *magna*; hindwings darkened by a dirty grey colour. It is distinguished by the abdomen being ashy-grey above. South East Peru. The ♂♂ are common, the ♀♀ not yet known.

M. insipida Rothsch. Size of *deserticola* (41 d). Head, chest, and legs slate-coloured, antennae reddish-grey; thorax, abdomen and forewings of a greyish-cinnamon colour. Hindwings greyish-white. Lagama (Argentina).

M. rubripes Blch. resembles *insipida*, and is just as large, of a dark red-brown with lighter hindwings. Recognizable by the rosy-red palpi and upper surface of the femora, as well as by the red abdomen with a black dorsal line. Chile.

21. Genus: *Antarctia* Hbn.

Very closely allied to the preceding genus, forewing with an accessory cell; body like in the *Mallocephala* with a long, shaggy hair-fleece. But in the species of which the ♀♀ are known, the latter are fully winged. More than 30 species are known, almost all of which inhabit the southern temperate zone of America.

A. vulpina Hbn. (= *pallicosta* Bsd., *uruguayensis* Berg) (41 d) is coloured almost like a large *Mallocephala latior* (41 d), dark-brown with dirty-white hindwings and a golden yellow abdomen which, however, is without the black dorsal bands, and differs besides by a creamy-white stripe along the costa. In the ♀ the hindwings and a costal stripe are of a more intense yellow-brownish tinge. — Larva quite black with black tubercles; across the dorsum a series of partly paired, yellowish-brown brushes. Very common in the pampas of Argentina and Uruguay, in January and February; in Montevideo in the Prado, and in the evening on lanterns in the streets.

A. felderi Rothsch. (41 f) is exactly like *vulpina* in its size and colours. Brown forewings, with a creamy yellow costal stripe in the ♂, dull white hindwings and yolk-coloured abdomen; only the colour of the forewing is not a dark chestnut brown, but a red-brown fox-coloured tint. From Rio de Janeiro. There are only 2 specimens known.

A. aurantiaca Rothsch. (41 f) is like the preceding, but the ♂ forewing yellowish-brown, without the costal stripe, in the ♀ yolk-coloured, the hindwings a little lighter. From Rio de Janeiro, through South Brazil and Paraguay as far as Bolivia.

A. lehmanni Rothsch. is somewhat larger; the only specimen known originates from Popayan in Colombia and is quite unicolorously greyish-white with orange-yellow abdominal sides, the antennal shaft white with a brown comb.

- brunnea*. **A. brunnea** Hbn. (= *severa* Berg) (41 d) resembles *vulpina* (41 d), but the forewings and the thorax are dark brown and without a light costa. The hindwings are dirty white, but in the ♂ their costal parts are of a dark, sooty tinge, whilst in *vulpina* only faintly darkened; the abdomen of the ♂ is not golden yellow, but brown. ♀ tinged quite honey-yellow. It often varies into a paler and more yellow form (= ab. **amaryllis** Schs.) South Brazil and Argentina, common. — Larva with dense, dark dorsal brushes, on *Xanthium spinosum*, *Gaillardia scabiosoides*, *Scleropus amaranthoides*, and other low plants.
- vulpecula*. **A. vulpecula** Dogn. Size of the following species, body dark brown, collar anteriorly red-brown, thorax more ochreous, abdomen covered with very long hair. Forewing blackish-brown, costal margin and the fringes still darker. Hindwings above white, somewhat lustrous blue, in the apical area darkened greyish. Beneath all the wings are of a leaden grey, costa, fringes and the apical part of the hindwing blackish. From Colombia. Described only according to male specimens.
- pallidivena*. **A. pallidivena** Schs. Size and shape of *azollae* (41 i). but the forewing with white veins like *venata* (41 i). Head and collar dark brown, thorax tan-coloured. Abdomen ochreous-yellow. Ground-colour of forewings tan-coloured. Under surface whitish, costal and distal margins of forewings brownish. Brazil: Castro (Paraná).
- honora*. **A. honora** Schs. (41 e) is almost exactly like the preceding, but the hindwings browner, also in the ♂ slightly tinged yellowish. The ♀ abdomen is of a brighter yellow. — This species is distributed from Central Brazil to the north and is even reported from Colombia.
- sericea*. **A. sericea** Schs. (41 e) is considerably lighter brown, also the ♂ forewings rather pale, the hindwings nearly white, except the costa and the inner-marginal area. South Brazil.
- fervida*. **A. fervida** Schs. (41 e). Only the ♀ is known. All the wings are dusted dark brown, without markings except the cell-end being faintly marked dark. Range like that of *sericea*.
- surgens*. **A. surgens** Wkr. (41 h, i). The ♀ has the forewing similar as *pallidivena* brown crossed by light veins, but the hindwings are of a dull white, towards the margin darker. The ♂ which was at first described as *Mallocephala venata* by ROTHSCHILD, is quite light whitish ochreous-yellow, the veins of the forewings purely white. Paraná.
- venata*. **A. venata** Schs. (41 i) resembles *surgens* in the marking, but it has a browner ground-colour of the wings, out of which the lighter veins (in the ♀ also on the hindwing) are more distinctly prominent, as well as yolk-coloured hair covering the body. But as HAMPSON places *surgens* to the genus *Maenas* being otherwise preponderantly palearctic, they must both be distinguished by the subcostal neuration of the forewings. Brazil: Paraná.
- albescens*. **A. albescens** Hmps. (41 e) from Venezuela and Peru has whitish wings tinged yellowish at the base, the thorax and abdomen, particularly posteriorly, being yolk-coloured. It must perhaps be already placed to the *Palustra*, like the following species *gigantea*.
- gigantea*. **A. gigantea** Jones belongs perhaps already to the next genus. Almost the size of *Palustra burmeisteri* (41 f, g); dark brown, collar bordered with a dark yolk-colour, abdomen yellow, above banded dark. Forewings brown, at the costal, proximal margins and border darker, in the distal area lighter and yellowish. Hindwings yellow, the costa narrowly brown. At the border an undulate band, being interrupted behind the cell. Border fine golden yellow. The last abdominal ring of the ♀ is brown; the ♀ also exhibits a very dull, dark postmedian line. Castro.
- rudis*. **A. rudis** Btlr. (41 i) was described as *Paracles* (comp. p. 320), but according to HAMPSON it belongs here, since the forewing shows an accessory cell. Lighter brown than the preceding, in the ♂ both wings coloured almost the same; thorax anteriorly and abdomen above tinged yellow. Chile.
- phacocera*. **A. phacocera** Hmps. Size of the preceding species, body dark brown, but a tuft on the shoulder and the abdomen orange. Forewings reddish-brown, the base covered with some orange hairs; hindwing orange with a dark brown marginal band, beginning broadly at the costa, and growing narrower towards the anal angle. Paraguay.
- paula*. **A. paula** Schs. (41 e) is much smaller than the other *Antarctia*, only the size of *Mallocephala deserticola* (41 d). Recognizable by the dark cell-end-spot and the ochreous-yellow inner-marginal stripe of the forewing. Hindwings of the ♂ darker. Brazil (Paraná).
- fulvicollis*. **A. fulvicollis** Hmps. Size of *paula* (41 e). Body dark brown, thorax above marked yellowish-red; abdomen above yellowish-red with a dark median stripe. Forewing dark brown at the base intermixed with some white and yellowish hairs. Hindwings yellowish-white, veins and border slightly suffused with a dark brown. Chile.
- costata*. **A. costata** Burm. (= *bergi* Schs.) (41 e). Size of *vulpina* (41 d), the side-form of which it was at first assumed to be. Antennal shaft above whitish, abdomen laterally dull yellow, in the ♀ above with brown bands. South Brazil (Rio).

A. thursbyi *Rothsch.* Head, thorax and forewings dark trunk-coloured, intermixed with small, yolk-coloured hairs and scales, chest and legs tinged orange-yellow; abdomen orange. Hindwings lighter, likewise tinted somewhat yolk-coloured. Size about like that of *vulpina* (41 d). Patagonia.

A. klagesi *Rothsch.* Size of the preceding; thorax and forewings dark chocolate-brown, somewhat wooden-brown. Hindwings quite wooden-brown. Abdomen orange, with an orange anal tuft. From the Upper Amazon (Fonteboa).

A. persimilis *Burm.* (41 f). Above dark sooty-brown, the disc of the wings faintly lighter. All the wings above and beneath with a distinct cell-end mark. Abdomen blackish-brown, in the ♂ with an orange-yellow lateral stripe, in the ♀ with dull yolk-coloured bands. South and Central Brazil, not rare.

A. fusca *Wkr.* (= *multifarior* *Burm.*) (41 h). Dark brown, larger than the preceding, ♀ with finely dusted forewings, ♂ with traces of a submarginal band behind the cell-end spot. Hindwings in the ♂ pale yellowish, dusted with a dull brown; abdomen dull orange-yellow, particularly on the sides, in the ♂ with dark dorsal bands. South Brazil and Argentina.

A. lateralis *Wkr.* Almost exactly like *persimilis*, but the forewings above somewhat mixed with grey and more intensely crossed by light veins. South Brazil.

A. marmorata *Rothsch.* (41 f). Dark earthy-brown with somewhat lighter hindwings. Forewing in the basal half with faded dark spots being the most prominent at, behind and below the cell-end. Teeth of antennae very long. Peru.

A. steinbachi *Rothsch.* (41 i) is almost exactly coloured and marked like a small *persimilis*; disc of the wings in the ♂ faintly lighter, in the ♀ with a distinct cell-end spot and a dark nebulous stripe before the marginal area. South Argentina.

A. nitida *Jones.* 35 mm; in the ♂ the head and thorax are dark brown, abdomen brown with lateral yellow stripes; forewings brown; hindwings creamy white, veins, costa and border brown. Beneath the forewings are brown, at the base with yellow hair, below the median as far as the proximal margin they are whitish; hindwings creamy white with the costal area intensely suffused with brown, and a brown cell-end lunula. From Castro, Paraná (Brazil).

A. reversa *Jones.* ♂ of the size of the preceding. Head and thorax dark red-brown, antennae lighter brown, abdomen above golden yellow. Forewings creamy-white, towards the margin brownish, veins red-brown; in the costal area a very dark band. Proximal margin as far as the submedian suffused with brown. Hindwings white with a brown costa. Castro (Paraná).

A. pectinalis *Jones* is larger, the antennae in the ♂ with very long pinnae. Body dark brown, abdomen orange; forewing brown, in the disc lighter and somewhat diaphanous, the proximal margin at the base covered with hair. Hindwings whitish, suffused with a yellowish brown. Castro.

A. cnethocampoides *Rothsch.* (41 e). Forewings more ashy-grey with a dark cell-end and a transverse chain of dark nebulous dots before the marginal area, whereby a faint resemblance is created to certain palearctic *Thaumetopoea*. From Salta in North Argentina.

A. variegata *Schs.* (41 i). With brighter and more variegated markings than the other. Forewings pale yellowish-grey; body dark brown, head, collar and an inner-marginal spot at the base of the forewing honey-coloured. On the forewing a dark postmedian band and a spot before and at the cell-end are blackish-brown, all these dark markings being bordered with white. Brazil: Paraná.

A. rhodosoma *Hmps.* is the size of the preceding, but recognizable by the red abdomen showing above small black dorsal spots, and by the semi-transparent, light hindwings. Forewings of a light reddish-brown with a yellowish base, at the discal spot tinted dark brown. Chile.

A. duckinfieldia *Schs.* (41 h). Only the ♀ is known. Thorax and wings earthy-brown, the wings crossed by thick, honey-coloured veins and similarly fringed. Abdomen yolk-coloured, dorsum and sides spotted dark. Abdominal end with orange-red hair. Central Brazil.

22. Genus: **Palustra** *Bar.*

The „water-arectia“ form a group very closely allied to the *Antarctia*, but owing to the peculiarity of their habits they have undergone great changes in order to adapt themselves to the aquatic life, particularly in their pupal stage. The ♀♀ of *Palustra burmeisteri* secrete much more anal wool than the European *Lymantria dispar*, a similar parallel prevalent between the Lymantriids *Porthesia similis* and *Euproctis chrysorrhoea* on the one hand and the *Scirpophaga* growing up in the water like *Palustra* on the other hand, the species of which have been denominated according to those Lymantriids *Scirpophaga „auriflua“* Z. and *Scirpophaga „chrysorrhoea“* Z. We have not allowed them to be confounded with other genera, such as *Maenas*, *Lacydes*, *Eutaenia*

etc., nor any genera at all represented in the Old World; much rather some species, having hitherto been dealt with as congeneric with the *Palustra*, could yet be eliminated. — The head, particularly in the ♀, is very much lowered, so that, on being seen from above, it does not project beyond the immense thoracic wool. Proboscis absent, palpi very small, turned directly downward. ♂ antennae with 2 rows of long teeth, in some almost the longest found in the Aretiids at all. The dense hairing of the thorax is sometimes shaggy or covers the whole thorax (*burmeisteri*), wings large, also the hindwings broad, with a short discocellular scarcely projecting beyond the middle of the wing; the discocellular forms a sharp, rather acute than obtuse angle. 9 species are known.

burmeisteri.

P. burmeisteri Berg (41 f, g) is one of the largest Aretiids in America, unicolorously dark brown, with a blackish cell-end spot, the forewing besides with a double, postmedian nebulous band. ♀ little lighter than the ♂, with a blackish abdomen and ochreous-yellow anal wool. — Larva large, stout, blackish-brown; the animals never rest on the surface of the water, but always about 10 to 15 cm below it on Potamogeton and other water-plants. The air needed for breathing is held fast by the dense hair on the larva, which, thereby receives a lustrous silvery cover. In order to renew this air, the larva sometimes comes to the surface; this is also done in order to swim over to another food-plant to which it is reported never to creep over below the water. According to GÜNTHER's observations the larva, in being bred, must sometimes have running water, lest it perishes in the skinning. The larva is dark, densely haired, the dorsal brushes in the early stage brownish, later on pale yellow. In spring (November) the pupation takes place. Then the larvae are seen swimming up the stream in numbers, in order to go into the small brooks and the drains (so-called Cañadas) traversing the pampas everywhere, where they leave the water for the sake of their pupation. According to observations by Willy Lehr (Baltimore), the larvae prefer projecting parts on the banks, where they mostly attach their downy spinnings on Stipa- and Carex-grasses. They often pupate gregariously (7 or 8 together), but the cocoons are spun in such a way as to be easily separated without being torn. The ♀♀ having crept out after few weeks keep sitting on the web where they also often deposit the eggs which are wrapped into the dense, downy anal wool of the ♀. Sometimes one ♀ sponges upon another ♀, depositing its own eggs in the downs of the eggs of the other. A remarkable fact is that the gluttonous, insectivorous fish *Heros facetus* Jen., which greedily devours the imagines of *Palustra*, disdains the larvae. The species is distributed across Uruguay and South Argentina; local, but in some places common.

affinis.

P. affinis Rothsch. is nearly exactly like *burmeisteri*, but the thorax is of a darker brown, the collar and hairing of the abdominal base yolk-coloured. From the Organ Mountains in Brazil.

ockendeni.

P. ockendeni Rothsch. (41 g). Also like *burmeisteri*, but the tegulae and the anal tuft are golden yellow and on the forewing of the only specimen known, a ♀, the postmedian transverse stripe is indistinct. Peru.

vivida.

P. vivida Rothsch. (41 h) resembles a small *burmeisteri*, but the abdomen is ochreous-yellow, in the ♂ with a series of blackish-brown dorsal spots, in the ♀ with dark bands; in the ♂ also the whole basal half of the hindwing is of a bright ochreous yellow; in the ♀ the disc of the hindwing is lighter greyish and somewhat diaphanous.

palmeri.

P. palmeri Rothsch. (41 g) is smaller than the preceding, body and wings quite unicolorously dark sooty brown, except the scarcely noticeably darker cell-end without any markings at all. Colombia.

haenschi.

P. haenschi Rothsch. (41 g) is nearly exactly like *burmeisteri*, but the ♀ shows a transverse band shaped brightening beyond the middle of the wing. — The larva is black, with rows of black, prick-shaped bristles. On the dorsum of each ring there is a transverse brush of dense, short, soft hair of a bright chestnut-brown colour.

laboulbeni.

P. laboulbeni Bar (= *argentina* Berg) (41 i). Light yellowish-brown, only about half the size of *burmeisteri*, forewings with dark ante- and postmedian, as well as antemarginal nebulous lines, and with a dull darker cell-end spot. — Larva with tufts of short bristles, and on the dorsum of each segment with a reverted, black, above rufous tuft. On *Mayaca fluviatilis* on which it feeds under the water. On being touched, the larva rolls up like most of the Aretiid larvae. Cocoon blackish, with interwoven larval hairs. South America, distributed in the east.

fosteri.

P. fosteri Rothsch. (43 a) somewhat resembles *laboulbeni*, but it is more stretched, the forewings lighter and quite unmarked; from Paraguay.

azollae.

P. azollae Berg (41 i) is still smaller, the hindwings in the ♂ golden yellow like the abdomen, with a reddish tint and dark margins; forewings as well as thorax dark brown, with still darker markings. Argentina.

tenuis.

P. tenuis Berg (41 c) greatly resembles *Mallocephala latior* (41 d), but it has deeper red-brown forewings and faint nebulous spots in the hindwing. The abdomen is orange-yellow like there, though without any black dorsal bands. ♀ with fully developed wings. Argentina.

P. juruana Btlr. (43 a). In the same way as *bilinea* (41 h) represents a small parallel form of *burmeisteri*, *juruana*. *juruana* resembles a pygmean form of *azollae*; hindwings lighter, except a brown distal-marginal band. Abdomen above yellow. Jurua River (Amazon).

P. flavata Hmps. (41 i). Here the forewings are also lighter, except the brown marginal band, and *flavata*. some small spots; colouring dull ochreous-yellow. The smallest species. Peru.

P. bilinea Schs. (41 h). The marking is almost the same as in *burmeisteri*, i. e. the forewing shows *bilinea*. beside the slightly angled cell-end spot interrupted ante- and postmedian nebulous lines; the latter are double. The ♂ abdomen is of a flesh-reddish colour except the base and apex. From Petropolis in South Brazil.

V. Arctiinae, genuine tiger-moths.

In this subdivision we find the typical characters of the whole family and in addition, as a merely external, though very conspicuous mark, a variety of contrasting colours, being most intensely developed. They are easily discerned from the pale, dull *Palustra*, the white *Spilosoma*, the narrow-winged *Phaegopterinae*, to all of which they are allied. In the neurulation they are not homogeneous, for which reason of late a number of internally undoubtful Arctiids, such as the *Callimorpha* in Europe, the *Platyprepia* in America, have been eliminated. They were separated from the *Arctiinae* as *Hypsidae* (in a more recent sense), chiefly owing to the fusion of two veins on the hindwing, which proceeding, however, was not followed by many authors who added the *Platyprepia* to the *Hyphoraia*. But even if this genus is included, the number of American *Arctiinae* is amazingly small; it only contains 5 species. Of the other American groups the genus *Apantesis*, both larvae and imagines, are the most closely allied; this genus, however, so exactly corresponds to our European genera *Orodemnias*, *Cletis* and *Euprepia*, that we have inserted it above at the corresponding place.

1. Genus: **Hyphoraia** Hbn.

This group is allied to the *Antarctia* by the clumsy, stout structure, the heavy posteriorly thickened abdomen of the ♀♀, the fleecy-like hairing, the long teeth of the doubly combed antennae, the broad wings and the fondness for dampness exhibited by the shaggily haired larvae; the *Hyphoraia*, however, pass their lives more under snow-covers than the *Palustra* living under the water.

H. subnebulosa Dyar (42 b). A small species, most closely allied to the palearctic *festiva*, but the *subnebulosa*. forewings are less spotted light, and the hindwings are not honey-coloured, but dull ochreous grey with a broad dark marginal band. Known from Alaska, and a rarity like most of the *Hyphoraia* (except *aulica*).

H. parthenos Harr. (= *borealis* Mschr.) (42 a). A very large species, almost the size of a *Pericallia parthenos*. *matronula*. Forewings thinly sealed, brown, spotted yellow, hindwings golden yellow, banded black. Easily distinguishable from *matronula* by the abdomen not being red, and the yellow spots on the forewing not only running along the costa. The butterfly is confined to Canada and the northern Atlantic States. Labrador, on the Upper Lake, on the Mackenzie River, everywhere rare; the specimens contained hitherto in the collections have mostly been taken at different places at long intervals.

H. hyperboreus Curt. The modern authors agree in this form not being separable from *alpina* Quensel *hyperboreus*. (= *thulea* Dalm.) which they, on the other hand, do not take to be separable from *lapponica* Thnbg. In Vol. II, we have figured both forms, *lapponica* and *alpina* (t. 17 e), and we refer to what has been said there (p. 95). *hyperborea* seems to be distributed over the whole of antarctic America. The species is so rare there, that it always costs about 3 or 4 dollars even in America.

2. Genus: **Platyprepia** Dyar.

The hindwings being in the ♀ of a bright golden yellow, with black ante- and postmedian bands, strongly recall *Pericallia matronula* from Europe and Northern Asia, and *Hyph. parthenos* from North America. The genus, however, is distinguished by the uppermost rib of the hindwing being fused with the cell-wall to a rather thick cord (= *Hypsidae* Hmps.). Larva and imago, however, are otherwise allied to our *Arctia*.

P. virginalis Bsd. (= *ochracea* Stretch) (42 a). Forewings black with rows of white guttiform spots, *virginalis*. hindwings of a bright yellow with black macular bands, in the ♂ sometimes with much black. — **guttata** Bsd. *guttata*. (42 a) has quite black hindwings except some honey-coloured guttiform, antemarginal spots, the abdomen is likewise above black and the white spots on the forewing stated by the author to be 18 are somewhat smaller. —

From the Rocky Mountains to the west as far as California, in Wyoming and Colorado in some parts common. One of the most beautiful North American Arctiids. The form *guttata* is much rarer.

3. Genus: **Arctia** *Schuk.*

As to this genus we refer to Vol. II, p. 97. In America only one species occurs, *caia* L., distributed over the whole northern temperate zone.

caia. **A. caia** L. America homes 4 or 5 forms of this most variable species: **utahensis** H. Edw. (= *auripennis* Btlr.) (42 a), with yellow hindwings like the form *wiskotti* Stgr. described from Eastern Asia., but slightly deviating from *transmontana* Neum. & Dyar, and **americana** Harr. (42 a) with red hindwings like the European *caia*, but at the shoulders with white lateral stripes of the thorax. Thereby it resembles the Japanese *phaeosoma* Btlr. (Vol. II, t. 18 b), but it is much smaller than this very large form, and the forewings are much more extensively brown, the broad white bands of the forewings of *phaeosoma* are narrow and thereby the brown areas more coherent. Certainly not all the North American specimens are so small and dark as the figured example, and in Alaska there occurs a form (**opulenta** H. Edw.) in which the white of the forewings is much intenser than in typical *americana*. Also in the east *caia* proceeds very far to the north, and there still remains a difference in size compared with the large Japanese with light and glaring bands, by which these two forms are easily discernible. Still more closely allied than to *phaeosoma*, *americana* is to the form *orientalis* Mr. (Vol. X, t. 24 i), but the latter has a quite differently marked abdomen, being broadly banded black from the 3rd ring, so that only the margins of the rings appear to be narrowly bordered with red, whereas *americana* shows a quite red dorsum of the abdomen with shortened black transverse bands. — The larva seems not to differ from the European. The species, however, is apparently in North America, although it is distributed over the whole northern United States, considerably rarer than on the eastern hemisphere, where it is, according to GRAESER's account, in some parts of the Amur District immensely common *).

VI. Phaegopterinae.

Most of the numerous (1060) species reckoned hereto exhibit a shape bearing a proportion to the general *Heterocera*-type about like that of the *Ithomiini* to the usual shape of the day-butterflies. In the *Ithomiini* ** (being generally known by the name of *Neotropidae*) we have noticed a slenderness of the hind body distantly recalling the shape of a dragon-fly, together with very long extended forewings and small round hindwings. Nearly in the same way we might characterize the *Phaegopterini* exhibiting the abdomen, though often not slender, but always extended, and another analogy is exhibited by the often uncommonly long antennae and legs. In *Opharus superba*, for instance, the antennae attain a length of $2\frac{1}{3}$ cm, the length of the forewings being only 4 cm, whereas in the *Arctiini* having been dealt with above the antennae scarcely ever surpass the middle of the costa; similar conditions are met with in the *Phaegopterina* *Calidota gigas* and in other species.

This resemblance of the shape to the *Ithomiini* might supply a good preparation to mimetic disguises, but in the present group we do not notice anywhere resemblances to the *Ithomiini* being allied in the shape. The *Phaegopterinae* are undoubtedly well protected. Some have extremely brilliant, magnificent colours, such as the *Belemnina*, sparkling like precious stones, and beside glittering metallic colours they exhibit yet glaring scarlet or orange bands. By their mostly very long and strong proboscis, the insects are able to delight in sucking from flowers, and they are not only without any frightening colours, but also mostly without colours resembling the soil, bark and leaves, which might be considered as an adaptation to the surroundings. The group, on the whole, shows little marking, except some genera (*Automolis*, *Idalus*, *Hyperthaema* etc.) showing a great variety of colours increased by spots, bands or stripes.

Another homology of the *Phaegopterinae* with the *Ithomiinae* consists in the same forms being frequently repeated in the different and more remote genera. In the same way as we see there e. g. the peculiar colouring of *Velamysta pardalis* Salv. repeated in *Dismenitis theudelinda* Hew., or as we recognize in *Hymenitis quinta* Stgr. an image of *Napeogenes hypaea* Stgr., *Ithomia dimidiata* Stgr., *Velamysta anomala* Stgr., *Episcada paradoxa* Stgr. etc., we also meet with repetitions in the *Phaegopterinae*; particularly species of the genus *Halisidota* recur also in other genera (*Agoraea*, *Elysius*, *Ammalo* etc.), mostly in a somewhat different size. We receive

* Most astounding is the enormous fecundity of this butterfly; LYLE (Entomologist 43. p. 249) reports that a captured *caia*-♀ deposited 1300 eggs, and that hereafter yet 150 eggs were found in its abdomen, thus together 1450, not counting the eggs which had been probably deposited, before it was taken.

** Comp. Vol. V, t. 32—11.

a rather similar impression of *Prumala argyllis*, *Ischnocampa nigrivena*, and *Pachydota nervosa* Fldr., all of which recall *Halisidota anapheoides*. But the resemblance is neither so astounding nor so unlike the forms of the nearest affinities, that we might notice a mimicry, i. e. an imitation obviously forcibly created by nature. There are only slight resemblances of poorly coloured markings, as we know in America also of the members of such families that have generally nothing to do with mimicry, such as Hesperids, Noctuids etc. We only remind the reader of similarities between the Hesperid *Potamanax unifasciata* Fldr. and certain forms of the Erycinid *Notheme eumeus* F., which may occur in all groups, often from quite different parts of the world.

In the nearetic region the *Phaegopterinae* form that group of Arctiids which most closely approximates the *Syntomidae*. Before the finer details in the anatomical structure had been paid attention to, some genera, such as *Belemnia*, were reckoned directly among the *Syntomidae*. In fact, the separation of the two is also somewhat artificial, as we recognize from the life-history. Quite a number of *Phaegopterinae*-larvae are known, many of them since a very long time, and on looking at these peculiar larvae we might be inclined to number the imagines yielded therefrom rather among the *Syntomidae* than to the Arctiids. Peculiar, pencil-shaped hair-brushes project from the anterior and posterior parts of the larva like threatening horns. In *Halisidota bactris* these pencils are orange-red on a black ground, in *Hal. rhomboides* black or white on a red and blue ground. In *Hal. catenulata* they stand apart behind the larva's neck like the sails of a windmill, and in *Thalesa citrina* all the rings between the anterior and posterior pencils exhibit lateral hair-brushes. The *Automolis* have on the 4th and 11th rings transverse hair-pads, behind which the long pencils are projecting. In *Pelochyta arontes* the 4th ring shows an enormous transverse pad parting the end of the larva's head like a Spanish collar, followed by variegated dorsal brushes and followed by long, peculiarly shaped pencils, some of which are thickened at the ends. The name of the genus „*Lophocampa*“, which has been introduced for certain *Halisidota*, is derived from these peculiar tufts of the larvae, and some larvae, such as those of *Eupseudosoma*, are so very much surrounded by brushes, that they resemble a ball of wool and hair-flocks, from which the head of the larva is separated by a bow-net-shaped collar. Hitherto every genus of *Phaegopterinae* has, in discovering its larva, surprised us, by disclosing a novel shape; in the other groups of *Arctiinae* we find this peculiarity only sometimes indicated (*Palustra*, *Isia*), but never developed to a similar extent. Certainly, however, the *Syntomidae* hereby resemble the *Phaegopterinae*, and in the *Encereum* in America, the *Euchromia* in Asia and Africa we see larval shapes closely approximating them. At any rate we are entitled to regard the *Phaegopterinae* mentioned here as being closely allied to many *Syntomidae*, so that a certain conformity also in the exterior shape of the butterflies must be more than an accidental convergence.

Beside the *Euchromia*, the palearctic genus *Rhodogastris* (Vol. X, p. 260 to 262, t. 25 d—g) exhibits an unmistakable affinity to the *Phaegopterinae*. Whosoever has chanced to observe the movements of the wings, the high-legged gait, the agility of the head in a *Rhodogastris astreus*, will be automatically reminded of the same peculiarities of *Halisidota tessellaris*. Even the flying to the light, the swarming, and the clumsy, somewhat *Neuroptera*-like settling down and running about on an illuminated wall is remarkably the same in both. The secretion of protective oil, all the joints moving quickly, the extremely tenacious life and some more subordinate peculiarities may be mentioned here as connections between the two groups. In Africa the *Phaegopterinae* are represented by the group of butterflies formed by the genera *Balaera*, *Metaretia* and *Apisa*, which, however, are already numbered among the *Syntomidae* owing to the scanty neuration of the hindwings.

The cocoons of the *Phaegopterinae* are nearly always uniformly, ovally woven and intermixed with hair of the larva, often exactly oviform, and loosely enclose the obtuse, faintly lustrous pupa.

1. Genus: **Cyanaretia** Hmps.

Proboscis strong; palpi porrect, strong, but with a rudimentary terminal joint. Antennae of more than half the costa's length with rather long teeth. Thorax broad, abdomen short. On the long forewing the 1st and 2nd subcostal veins rise before the end of the long, narrow cell. The uppermost median vein (last radial) rises from the lower cell-angle, the 2nd radial vein little above it. Hitherto 3 rather dissimilar species are known, having formerly been allotted to 2 different *Syntomid* genera.

C. dama Drc. (42 b). From Mexico; blackish-grey with hyaline patches in the wings; the forewing *dama*, shows a metallie blue reflection at the costal margin, a coppery reflection at the proximal margin.

C. ruscia Drc. (42 b). From Bolivia. Lustrous blackish-brown with an oblique orange band of the *ruscia*, forewing and some orange antemarginal spots of the hindwing.

C. flavinigra Dogn. is founded upon a single ♀. In the forewing a very broad, yellow band extending *flavinigra*, towards the border immediately above the proximal angle. Hindwings quite black. West Colombia.

2. Genus: **Belemnia** Wkr.

Charming, small butterflies looking like *Syntomidae* with variegated and metallic lustrous spots on a jet-black, velvety ground. Proboscis strong, palpi slightly raised, short, the antennae long, the teeth suddenly decreasing before the tips of the antennae Thorax round, abdomen broad, the hindwing in the ♂ often with a pointedly extended anal angle. The 10 forms known have nearly all the same size; they rest on blossoms, together with *Cyanopepla* and *Macrocneme*-species and fly in the sunshine in a similar way as the *Zygaena*-species do.

- eryx*. **B. eryx** F. (= *obscura* Drc.) *. Forewing with a brassy lustrous basal part and a bright hemochrome, small discal band. Hindwing with a pointedly extended anal angle. Colombia and in the Amazon District as far as Bolivia, dispersed. — In *crameri* Btlr. (= *inaurata* Cr. nec Sulz.) the small red band of the forewing is duller and more obtuse, often also shorter or narrower. Brazil and Bolivia, particularly common on the Amazon.
- inaurata*. **B. inaurata** Sulz. (= *eryx* Roem., *jovis* Btlr.) (42 c) is similar, larger, the anal angle of the hindwing in the ♂ roundish; basal half of the forewing of a lustrous bluish-green instead of brassy golden, the hemochrome band of the forewing above broader than beneath (in *eryx* just the contrary). Mexico and Central America. — In the form *rezia* Drc. (42 c) from Colombia the red band of the forewing is broader and extends farther down, on the under surface down to the proximal angle. Common.
- ochriplaga*. **B. ochriplaga** Hmps. (42 c). The small band of the forewing is narrower and orange-yellow, the basal part of the forewing less lustrous. On the Amazon River everywhere; near Para, Ega, Humayta etc. The figured specimen from South Brazil.
- lydia*. **B. lydia** Drc. (42 c). Body with golden red spots and bands. Forewing at the base little metallic with small dull bluish-grey spots at the cell-end. Colombia. Apparently rare.
- mygdon*. **B. mygdon** Drc. (42 b). Forewing above without any transverse band at all, but the whole basal part of a bright golden lustre, crossed by black veins. Beneath the small red transverse band is visible. Colombia. — In *marthae* Rothsch. from Sa. Martha in Colombia the small band beneath slightly shows through above.
- aplaga*. **B. aplaga** Hmps. (42 b) is similar to *mygdon*, above entirely without the small transverse band appearing also beneath merely as a faint red trace. Forewing in the basal half with a coppery lustre. Ecuador, Paramba; the figured specimen taken by R. HAENSCH in July.
- alpha*. **B. alpha** Drc. (42 c) entirely recalls *Syntomids* from the genus *Cyanopepla* together with which it also flies, particularly from the affinities of *C. cinctipennis* (22 g) or *quadricolor* (22 f), but it is easily recognizable by the whitish apical spot of the forewing. From the volcan de Chiriqui in Costa Rica.

3. Genus: **Diospage** Wkr.

Very closely allied to the preceding genus, but in the hindwing the subcostal vein, which is feeble or absent in *Belemnia*, is strong, and vein 5 being absent there is present here. The structure is usually somewhat more slender, and the anal angle of the hindwing is not pointedly extended as in *Bel. eryx dubia*.

- chrysobasis*. **D. chrysobasis** Hmps. (42 d). Forewings as in *Bel. inaurata*, but the hindwings broadly bordered with a purple red. Colombia, Bolivia and Peru.
- semimarginata*. **D. semimarginata** Rothsch. Forewings similar to those of the preceding; hindwings thinly bordered with pink, before the middle of the border a narrow, purple, longitudinal spot. Paramba (Ecuador). 2 ♂♂ in the Tring Museum.
- splendens*. **D. splendens** Drc. (42 d). The small band of the forewing is narrow and of a dull pink, an antemarginal, broad red band on the hindwing is crossed by the black veins. Bolivia, Peru.
- cleasa*. **D. cleasa** Drc. (42 c). Above quite black, only the bases of abdomen and of hindwings with a metallic golden green lustre. Beneath there is behind the middle of the forewing a broad, bent transverse band, in the hindwing the whole distal half is hemochrome, and besides the venter, too. Colombia to Ecuador.
- steinbachi*. **D. steinbachi** Rothsch. (42 d). Forewing in the basal third bronze-green, in the cell an indistinct red spot, a postcellular light red band from veins 4 to 9. Hindwing black with a metallic lustrous base. Beneath in the disc of all the wings irregular hemochrome spots. Bolivia.
- violitincta*. **D. violitincta** Rothsch. (42 d). Black, the proximal half of the forewing coppery golden, crossed by the black veins, quite similarly to the *Belemnia aplaga* (42 b). Beneath the wings are in the basal halves metallic blue. Cauca Valley, May to July.

* The form represented by HUEBNER in his „Sammlg. Exot. Schmett.“ as *gemmans eryx*, was recently separated from it under the name of *dubia* Ky.

D. engelkei *Rothsch.* (42 c). Above velvety black with a golden green base of the hindwing, the forewing *engelkei*. towards the margin velvety brown. Beneath all the wings have green golden bases and a postcellular, golden green, small transverse band. From Ecuador.

D. rhebus *Cr.* (42 d). Both wings with a bluish-green lustrous basal half, beyond the middle of the *rhebus*. forewing 2 parted, small white spots. Upper Amazon; São Paulo de Olivença. Ega, Fonteboa etc.

D. carilla *Schs.* (= *eerilla Strd.*). Very similar to a *Belemniastis troetschi* (42 e): body with a metallic *carilla*. golden green lustre, also on the basal parts of the velvety black wings; beyond the middle of the forewing a broad, ochreous-yellow transverse band. Carillo in Costa Rica.

4. Genus: **Belemniastis** *Hmps.*

Hampson established this genus for 3 species allied to the preceding, but distinguished from *Belemnia* by the 2nd subcostal vein rising from the same place with the footstalk of the 3rd to 5th, but running separated from the latter, whereas in *Belemnia* the branches 2 to 5 rise on a common pedicle. The butterflies seem to be considerably rarer than the *Belemnia*.

B. troetschi *Drc.* (42 e). Forewing with a broad orange oblique band before the apical third; in the *troetschi*. ♂ this band is dark orange, in the ♀ orange-yellow. Costa Rica, Panama.

B. whiteleyi *Drc.* (42 d) is larger than the preceding. Forewing with a bronze-golden basal part and *whiteleyi*. a white postcellular oblique band, hindwing beginning from the base radiantly blue. Guiana and Amazon.

B. attidates *Drc.* (42 e). Forewings with 2 purple oblique bands, otherwise similar to the preceding. *attidates*. Colombia. A striking resemblance in the shape, colouring and marking exists between this Arctiid and the Syntomid *Napata splendida* (21 a) flying in the same country.

5. Genus: **Metaxanthia** *Hmps.*

This genus, like the preceding, shows homochromatic mutual relations with the Syntomids which the insects also resemble in the habitus, but by the completer neuration in the hindwing they are to be placed here. Palpi long with a distinct terminal joint, bent up before the forehead; proboscis long; on the forewing the 2nd to 5th subcostal veins are petioled, whereas the 1st rises rather far before the end of the long cell. On the hindwing the discocellular is doubly angled.

M. vespiformis *Drc.* (42 e). Body black, beginning from the 4th ring yellowish-red, abdominal end *vespiformis*. yellow. The wings are diaphanous, of a smoky dullness, the veins black. Colombia and Amazon as far as Peru. Apparently not common. In the light falling from the side on the wings, they show, particularly the hindwings, a magnificent Nile-green reflection. It has an extraordinary resemblance to the Syntomids *Osmocneme braccata* *Draudt* (29 d) and *Ixylasia pyroproctis* *Drc.* (29 d), also to certain *Gymnelia*, mostly species together with which the *Metaxanthia* fly.

M. threnodes *Drc.* (42 e). Smaller, body black, only the chest and abdominal end bone-coloured. *threnodes*. Forewings sooty black, the distal third hyaline, as well as the hindwings with jet-black veins. Hindwings hyaline, towards the apex smoky. Captured by A. H. FASSL on the Rio Songo. It strongly recalls certain Syntomids from the affinities of the *Pseudomyia*.

6. Genus: **Stenophaea** *Hmps.*

Shape and size of the preceding genus, but palpi with entirely stunted terminal joints; the 2nd subcostal vein of the forewing is not petioled with the others, but rises before the cell-end, and the discocellular which was angled there (on the hindwing even doubly angled), is here but slightly curved in. 2 similar species, both of which extend from Mexico to Honduras.

S. pollinia *Bsd.* (42 e). Brown, collar and abdomen red. Forewing with a yellow costal stripe, hindwing *pollinia*. with a transparent basal part.

S. salatis *Bsd.* (42 e) resembles the preceding, but the abdomen is black, forewing without the *salatis*. yellow costal-marginal stripe.

7. Genus: **Glaucostola** *Hmps.*

Owing to its exterior resemblance with *Leucopsumis* the only species on which HAMPSON founded this genus was described as such. In the habitus it resembles also certain *Agryta* (e. g. *pandemia* 24 b) and in the open air it is probably scarcely discernible from other *Syntomidae*, such as *Cyanopepla glaucopoides* (23 b), *Ixylasia schausi* (22 b), *Mydromera isthmia* (23 i), where it flies together with them. Proboscis strong, the

palpi being bent up before the forehead have a long middle joint, but a stunted terminal joint; the antennae in the ♂ rather long-combed. In the submedian fold the ♂ shows an oblong scent-spot below the middle of the cell on the forewing beneath; this spot is covered by a lobular indentation of the costal part of the hindwing, by which formation the species approximates the *Neritos* from which, however, HAMPSON separates it far, owing to the different subcostal system of the forewings.

- guttipalpis*. **G. guttipalpis** Wkr. (= *romula* Drc.) (42 f). Body grey with an orange-yellow head and ventral end. Forewing grey with a white oblique oval, hindwing black with a white, somewhat diaphanous, wedge-shaped spot from the base. — In ab. *underwoodi* Rothsch. (42 f) the white spot of the forewing above is shaded with the ground-colour and shows but faintly through from beneath. — Costa Rica and Brazil; both forms fly together on the Orosi.
- flavida*. **G. flavida** Schs. Thorax and forewings greyish-brown; behind the head somewhat yellow. At the base of the proximal margin a dark yellow streak; at the cell-end a dark yellow oblique shade. Abdomen and hindwings dark yellow. Beneath the forewings are tinted yellow. Expanse of wings: 37 mm. From French Guiana.
- metaxantha*. **G. metaxantha** Schs. (42 f). Head orange with a black vertical dot. Palpi and legs brownish-grey; collar orange with small black spots. Thorax blackish-patagia inside bordered with yellow. Abdomen orange, before its end a black transverse band. Forewings dark brown, on the costa, in the cell and above the proximal margin pale streaks, as well as above vein 2. Behind the cell a white oblique band from the subcostal to vein 3, near the margin. At the base, below the cell a long, pointed, white spot. Hindwing at the base and proximal margin yellow, distal part from the middle of the costa and from behind the anal angle black. Expanse of wings: 34 mm. Costa Rica. The species has a remote resemblance with certain *Automolis* (*marginata*-group).
- binotata*. **G. binotata** Schs. resembles *metaxantha*; the black-veined, grey forewing has below the cell a faded spot, behind the cell a large, whitish spot; hindwing at the base yellow, in the marginal area black. Abdomen yellow with a black dorsal stripe and end. 26 mm. British Guiana.

8. Genus: **Haemanota** Hmps.

A small butterfly with unicolorously dark wings and red thorax. Proboscis strong, palpi long, obliquely bent up with a very long middle and short, conical terminal joint. The hindwing is without vein 5; on the forewing the cell is very long, the discocellular almost forms a right angle. No areola.

- cubana*. **H. cubana** Rothsch. (43 b) is blackish-brown, thorax as well as the base of the forewing earmine. Guiana and Cuba. (According to STRAND this form, not lying before us, is identical with *Neritos sanguidorsia* from Guiana, having been described by SCHAUS.)
- rubriceps*. **H. rubriceps** Hmps. (43 b) is quite similar, somewhat larger, the wings broader, more dark slate-coloured, and the metathorax is not red, but dark blackish-brown like the abdomen. From South Brazil.

9. Genus: **Tessellota** Hmps.

To this genus belong 4 similar species apparently confined to the southern parts of South America; they are rather small, insignificantly coloured animals. Proboscis and palpi are stunted, antennae in the ♂ combed, in the ♀ almost plain. Forewing with a very long cell. Abdomen brightly coloured, with 3 rows of dots.

- sertata*. **T. sertata** Berg (= *apiola* Drc.) (42 f). The most common species. Bone-coloured, the forewing decorated with distinct, small brown circles and with a brown, irregular wedge-shaped spot beginning before the distal third at the costal margin and extending across the middle of the wing, gradually widening, to the proximal margin. Abdomen above orange with median and lateral rows of dots, beneath white. South Brazil, Uruguay and Argentina; the figured specimen I took at Buenos Ayres on a lantern in February.
- trifasciata*. **T. trifasciata** Burm. (42 f). Instead of the brown cuneiform spot, 3 irregular, pale brown bands cross the forewing. Argentina.
- cancellata*. **T. cancellata** Burm. greatly resembles the preceding in the colouring, but only one band, straight through the middle of the wing, is developed. Brownish spotting at the base of the costa and in the middle of the margin. Size of the preceding. Argentina.
- apostata*. **T. apostata** Schs. from Castro in the Brazilian State of Paraná, presumably scarcely belongs to this genus, for the proboscis being developed in the other *Tessellota* is stunted, and on the forewing the veins 8 and 9 are fused. Black; 2 spots on the hindhead, collar, the last abdominal ring and dull spots on the preceding ones orange. Legs and the antennae with long, double combs are black. Forewings semi-diaphanous black, thinly sealed, tinted brownish. Hindwings black, almost opaque. 29 mm.

10. Genus: **Baritius** Wkr.

In its new arrangement founded by HAMPSON the genus is likely to comprise a very great number of species, most of which are probably yet to be discovered in the tropics of South America. In 1901 only 6 species were known; at the outbreak of the war, which terminates our literary knowledge of them their numbers known to us had trebled. The exterior of the single species is derived from other groups of night-butterflies flying together with the *Baritius*, so that they partly resemble certain *Halisidota* (subgen. typ. *Baritius*), partly *Eucereum* (subgen. *Pseudeucereon* Mschlr.), partly also *Syntomidae* from the genus *Autochloris* (subgen. *Thysanoprymna*); the latter sometimes to such an extent that certain species were described as *Syntomidae* (*B. superba* as *Aclytia* etc.). — Proboscis developed, antennae doubly combed; on the forewing the 1st subcostal vein rises far before the cell-end, it then detaches the 2nd, and the 3rd is petioled with the 4th and 5th. The upper radial comes from the upper cell-angle, the middle and last radials rise from the same place, the lower cell-angle. Also on the hindwing the subcostal vein rises before the transverse vein. In spite of the conformity in this somewhat uncommon neuration, it is presumably a mixed genus; some species have a hair-lock at the base of the posterior femora, and the palpi bent up, others are without this hair-tuft and the palpi are porrect, sometimes the transverse vein of the forewing is straight, sometimes strongly angled etc.

A. Forewings blackish, abdomen of a more or less bright red.

B. pyrrhopyga Wkr. (42 f). Body jet-black, the abdominal end scarlet, in the ♂ besides a yellow *pyrrhopyga* anal tuft. Forewing sooty black, behind the cell and at the base of the wing more pronounced; hindwing hyaline, except the broad black border, sooty dark and with black veins. Brazil.

B. haemorrhoides Schs. (42 f) greatly resembles the preceding, but the red colour at the abdominal *haemorrhoides* end is more extensive, the blackish forewings reflecting somewhat violet exhibit beside the basal third a median transverse jet-black band greatly widening in the middle, and the apex of the forewing is likewise jet-black. Costa Rica.

B. roseocincta sp. nov. (42 g) from Colombia (Villavicencio) has all the abdominal rings banded *roseocincta* purple pink, but these purple bands are covered with black hair in the basal half of the abdomen. The black border of the hindwing is narrower than in the preceding, in the middle of the distal margin the hyaline spot approaches almost to the border.

B. superba Schs. (42 g). The bright deep red abdominal ring only narrowly bordered with black; *superba* border of hindwing broad black. The blackish-brown forewing does not show in the typical form any dark transverse bands, but a dark longitudinal ray on the median, dark oblique diffuse patches from there to the proximal margin, and a dark diffuse spot before the apex. Mexico and the adjoining parts of Central America, not rare. — **B. cepiana** Drc. from Venezuela is marked and coloured like *superba*, but the marking of the forewing *cepiana* is like in *morio* arranged in 3 transverse bands.

B. morio sp. nov. (42 g) is larger than the preceding; the forewing with 3 narrow, black transverse *morio* bands (the distal one interrupted); on the hindwing the hyaline spot in the ♂ is much smaller, in the ♀ it is quite absent; abdomen with narrow, dark red bands. Costa Rica.

B. drucei Rothsch. Forewing dirty blackish-grey, in the disc somewhat transparent. Hindwings *drucei* lighter; abdomen blackish, the posterior part and sides slightly banded pink. Caracas. (Size not mentioned.)

B. peculiaris Rothsch. In the ♂ the legs, head and thorax are black, abdomen black, posteriorly *peculiaris* outside carmine, last ring golden yellow. Venter at the base of abdomen red. Forewings hyaline, at the cell-apex a black streak; base, costa, veins, apex and border as well as the proximal margin black. Hindwings diaphanous hyaline, veins as well as margins black; at the anal angle a black spot. Expanse about 36 mm. Unknown to me.

B. Forewings yellow to ochreous-brown, abdomen yellow or rosy.

B. marmorea Schs. (42 g). The basal and costal parts of the forewing as well as the head and collar *marmorea* honey-coloured, the rest of the forewing speckled red is of a dirty greyish-brown, powdered white. The basal third as well as the cell are defined by a dark transverse band. Before the border of the forewing a white line, and white discoloration above the proximal margin. Abdomen and hindwings pale yellowish-pink. From Costa Rica to South Brazil (Rio Grande do Sul) and Bolivia (Rio Songo), but mostly not common.

B. discalis Wkr. (42 g) is larger than *marmorea*, the honey-coloured forewing with 9 red-brown *discalis* dentate lines, between which darker yellow transverse bands change off with more lemon-coloured ones with darker yellow pupils. Abdomen dark rosy-red, hindwings of a deep flesh-colour. Recalls some *Halisidota*-species. South Brazil (Rio).

B. brunnea Hmps. is much smaller than the preceding, the expanse only 32 mm; forewing dull brown; *brunnea* abdomen dark brown, at the end and sides yellow. Dark bands before the middle of the forewing, in the middle

from the cell to the proximal margin, behind the middle an irregular band, besides a cell-end spot. On the hindwing the submedian fold is tinged orange. Brazil, from the Amazon to South Brazil.

eleuthera. **B. eleuthera** Stoll (42 h). Size and shape of the preceding, of a paler yellow, the forewing strewn with brown atoms and whitish crescents, the latter bordered darker and intermixed with roundish spots. Before the middle an indistinct, dark transverse band forking towards the costa. Abdomen and hindwing with a dull rosy-red tinge. From Surinam to Bolivia; apparently wide-spread, but not common.

eleutheroi-
des. **B. eleutheroides** Rothsch. Expanse: 25 (♂) to 30 (♀) mm; similar to *eleuthera*, but the wings much narrower, all the brown markings wider, more irregular, the lines bordering on the markings not so distinct. Surinam to Peru.

flavescens. **B. flavescens** Rothsch. (42 h) is rather small, pale sulphurous yellow, with very irregular brown markings and between them some white guttiform spots encircled dark. Hindwing pale yellow, only in the inner-marginal half with a faint reddish-tinge. Abdomen above tinted yellowish-red. Described according to 1 ♂ from Fonte Boa on the Amazon.

affinis. **B. affinis** Rothsch. likewise from Fonte Boa, resembles *flavescens*, but the forewing with a net of fine brown markings, 3 dark brown costal spots and an interrupted, brown, antemedian transverse band; there are also brown spots above the proximal margin, before the apex and behind the middle; abdomen of a bright rosy-red.

schausi. **B. schausi** Rothsch. is the most closely allied to *marmorea* (42 g); on the forewing the ground-colour is a dull violettish-brown, crossed by numerous, irregular rows of yellow, red-centred rings. Hindwings pale and somewhat diaphanous yellowish-pink, abdomen pink. From Trinidad through Venezuela and Colombia to the Amazon.

sannionis. **B. sannionis** Rothsch. from the Upper Amazon has golden yellow head and tegulae, the latter with a black centre; palpi carmine, outside bordered with brown. Patagia and thorax brown, speckled carmine and yellow. Abdomen carmine, the last segment golden yellow. Forewing red-brown, faintly strewn with yellow; base yellow with 2 carmine dots; hereafter a transverse band of carmine spots bordered with yellow. Discal and postdiscal area with 3 or 4 irregular macular bands bordered with yellow; in the dark marginal line a series of small, carmine dots. Hindwings transparent rosy, washed over with golden yellowish. Expanse scarcely more than 20 mm.

venata. **B. venata** Rothsch. Head and thorax buff with paler and red spots. Abdomen dirty brick-red. Forewings buff, all the veins marked with a broad light brick-red. Basal half of forewing irregularly spotted dark brown and dotted black; a postmedian, dark brown transverse line. At the border and before it rows of small dark internerval spots. Hindwings rosy-red. Expanse of wings: 32 mm. Surinam. — This species structurally deviates more from the other *Baritius*, for which reason HAMPSON established the genus *Haemaphlebia* for it. — To this belongs also

strigata. **B. strigata** Jones (43 b). Size about that of *marmorea* (42 g); the forewings buff with numerous red transverse bands and lines, as well as small spots in the marginal area; the hindwing in the costal half ochreous yellowish, in the anal half pale pink. From Santos in South Brazil.

11. Genus: **Syntaretia** Hmps.

Hereto belong but few, similar species distributed from the Amazon to the north as far as Surinam, Venezuela, and Trinidad. In their exterior they somewhat recall a small *Halisidota* and show a plain, pale yellow or brownish colouring with a fine undulate marking on the forewing. Antennae, proboscis and palpi as in *Baritius* from which they chiefly differ by the narrower cells of all the wings, particularly of the forewings, and by the absence of the subcostal vein of the hindwing. In the latter respect they resemble the *Tricypha*, but these deviate from them and all the other Arctiids by the entirely distorted system of the subcostal veins on the male forewings.

oenone. **S. oenone** Btlr. (42 h). Right across the pale-yellow, rather pointed forewing extends a number of mostly paired, reddish-yellow streaks, between which there are subcostally some irregular dots. From Venezuela and Guiana through South America as far as Brazil and Ecuador.

fasciata. **S. fasciata** Rothsch. (42 h) from Fonte Boa on the Amazon resembles *oenone* in size and shape, but it has across the pale yellow forewing broad, greyish-brown transverse bands.

russus. **S. russus** Rothsch. has light brown head, thorax and forewings, the latter crossed by numerous brown, partly irregular zig-zag lines. Before and through the middle extends one broader zig-zag band each. Size and shape like the following. Unknown to me; patria not stated.

S. testacea *Mschlr.* (43 b) is almost exactly like *oenone*, but the transverse lines are not so regular, *testacea*, frequently interrupted and more entangled. Surinam and Trinidad as far as the Amazon.

12. Genus: **Tricypha** *Hmps.*

The few species known of this genus are at once recognizable by the ♂ forewings being quite uncommonly widened. The cell forms a broad wedge, the costal margin is thereby uncommonly curved, the apex rounded off. In this broadly extended wing the 3rd subcostal vein immediately after having left the upper cell-angle turns downward and terminates into the upper radial, or rather forms it, directly before the border. In the ♀ the venation of the forewing is similar to that of *Baritius*, except the lower radial and upper median having a short footstalk. The distortion of the ♂ forewing produced by this course of the vein makes the wing appear plaited in the living imago; the apical area forms a vesicularly raised surface and the distal margin is slightly drawn in below the somewhat projecting apical part.

T. imperialis *Heyl.* (= *anomala* *Drc.*) (42 i). Dark sooty brown in and behind the cell, as well as *imperialis*, in the submedian fold in the ♂ semi-diaphanous, longitudinal, diffuse spots. Abdomen beneath orange. From Mexico to Brazil and Bolivia, but apparently nowhere common.

T. furcata *Mschlr.* (= *anomala* *Btlr.* nec *Drc.*) is very similar to the preceding, but somewhat smaller *furcata*, and the abdomen beneath not orange, but greyish-brown. Guiana and Amazon.

T. nigrescens *Rothsch.* (42 i) is somewhat larger than the preceding, coloured the same, but with *nigrescens*, a red transverse spot at the vertex and a yolk-coloured apex of the abdomen. Paraguay.

13. Genus: **Hypocrisias** *Hmps.*

These butterflies, with an almost Noctuid-like habitus, are not properly inserted here and are also placed to the end of the whole group of genera in HAMPSON'S Catalogue, before the Philippine Arctiid (neither fitting to its surroundings) *Heliozona lianga*, the female type of which we have figured in Vol. X, t. 19 a. The most closely allied to the *Hypocrisias* are the *Halisidota*, by which name most have been described. — Proboscis developed, palpi with an entirely stunted terminal joint, ♂ antennae rather long-combed, the 2nd subcostal vein of the forewing rises directly behind the rise of the 1st, before the upper cell-angle, the discocellulars only slightly curved in. Medium-sized, pale yellowish-grey butterflies marked greyish-brown.

H. punctata *Drc.* (= *minima* *Drc.* nec *Neum.*) (42 i). A very common Mexican butterfly, often *punctata*, captured by the lantern. Pale yellow with 4 brown transverse bands on the forewing: before, in and behind the middle and at the border; before the latter small round rings with light centres. Abdomen above blackish. Occurs also in Central America.

H. minima *Neum.* (= *armillata* *H.-Edw.*, *agelia* *Drc.*) (42 i) entirely resembles *punctata*, but the *minima*, brown bands of the forewing flow together in the discal area to a large spot; the hindwing at the margin less darkened. Mexico; proceeds to the north as far as the United States and was taken in July in Arizona.

H. gemella *Schs.* (= *emella* *Strd.*) likewise resembles *punctata*. Head and neck cinnamon-brown, *gemella*, abdomen brownish buff, so are the forewings with brown transverse lines; a dark brown antemedian shade, indented at the basal part. At the costa a spot in the middle, one at the cell-end; a light buff postmedian spot is bordered with brown. An antemarginal row of spots partly replaced by a brown dot; veins, a marginal line and fringes brown. Hindwings white, tinged brown, veins and marginal line brown. 38 mm. Costa Rica.

H. fuscipennis *Burm.* (42 i). Shape and size of a *Halisidota*; thorax and forewings greyish-brown, *fuscipennis*, shoulder-covers with a thick, dark dot, subcostal area of the forewing and basal part of the hindwing bone-coloured, abdomen orange; from Argentina.

H. jonesi *Schs.* (42 k) greatly resembles the preceding, but the whole proximal area of the forewing *jonesi*, is bone-coloured, and in the brownish-grey distal area there are bone-coloured spots. Hindwings quite bone-coloured. From Paraná.

H. lisoma *Dyar* (42 k) resembles the preceding, of a dirty yellowish-white, shaded rather dark brown. *lisoma*. On the forewing the brown shading is badly defined, the marginal area rather narrow, interrupted by an undulate band of the ground-colour. Discal spot reniform, encircled by brown, but not very prominent. Hindwing with an antemarginal nebulous band. Mexico.

H. berthula *Dyar* (42 k) is larger than *minima* *Neum.* which it otherwise resembles, but the light *berthula*, antemarginal band is much narrower than there, not the whole base of the forewing is yellow, but only a sub-basal yellow band; hindwing with a discoidal spot. Tehuacan in Mexico; discovered by ROBERT MÜLLER.

14. Genus: **Tessellarectia**.

Medium-sized butterflies, allied to the preceding, with pale, yellowish grey or brownish wings and a bright red or orange-yellow abdomen spotted transversely above. Proboscis well developed; palpi rising, but very short, the middle joint being shortened, the terminal joint stunted and almost entirely vanished. No accessory cell; the 2nd subcostal vein rises separately from the upper cell-wall, before the cell-end. 3 species are known being confined to South Brazil and all rare; a 4th species, from the Upper Amazon, deviates structurally to such an extent that HAMPSON established a new genus — *Pydnaodes* — for it. In this species also the abdomen is unicolorously brown, not yellow or red with black transverse bands as in the genuine *Tessellarectia*.

- cinerascens*. **T. cinerascens** Wkr. (43 b) is rather similar to *Hypocrisias jonesi*, but the abdomen is above marked black, and in the distal area of the forewing the bone-white colour almost entirely displaces the brown ground-colour. Hindwing except a light costal-marginal spot quite dark brown. South Brazil.
- semivaria*. **T. semivaria** Wkr. is smaller and has light, netted brown spots only in the basal part of the forewing at the middle of the costa and round the apex; the abdomen is above purple. South Brazil.
- ursina*. **T. ursina** Schs. has almost quite brown wings, only at the base, at the costa and cell-end, and before the border of the forewing there are small bone-white or reddish-yellow spots; abdomen in the ♂ above scarlet with black transverse spots. South Brazil.
- distincta*. **T. distincta** Roths. (43 b), the only northern species, from Fonte Boa on the Amazon, shows yellowish brick-coloured forewings; above the proximal margin a dark brown, half oval light buff longitudinal spot; the distal $\frac{3}{4}$ of the proximal margin broadly leather-white. Along the border a whitish leather-coloured line. A subapical dark brown spot touches an irregular oblique band and connects it almost with the spot above the proximal margin. This band is on both sides bordered by an interrupted white line. Hindwings dull orange-brown, with irregular dirty-brown bands and spots. Abdomen brown. HAMPSON establishes a genus of its own for this single species: *Pydnaodes*.

15. Genus: **Ochrodota** Hmps.

Distinguished by the considerably broader wings, by the longer middle palpal joint and the subcostal vein of the hindwing rising from the middle of the upper cell-wall. The species, all of which, except one, were described only in the last decade, are very much alike.

- pronapides*. **O. pronapides** Drc. (43 a) is entirely marked like the *Tessellarectia*, earth-brown clouds on the forewing alternating with bone-white, netted brown patches. The brown colouring in the middle of the forewing is proximally defined by a line extending from the middle of the costa in a slight curve to the submedian fold and from there to the base of the wing. Abdomen yolk-coloured; hindwings brown, in some places light yellowish.
- major*. From Guiana through the Amazon District to Ecuador. — **major** Roths. is a large ♀ from the Volcan de Chiriqui.
- marina*. **O. marina** Schs. Forehead light brown, vertex whitish, tegulae and patagia white, bordered with brown; thorax posteriorly dark brown, abdomen yellow with black lateral spots and a black subdorsal spot at the end. Forewings dark brown, the darkest along the proximal margin, in the middle before vein 2 and behind the cell; base, the median space above the submedian, the cell next to its end and the costal margin at the cell-end whitish with reddish-brown rings and irregular lines. Apical part above vein 6 also whitish with similar lines. Hindwings yellow, border black, narrower at the anal angle as well as at the apex. Under surface similar, paler. Expanse of wings: 33 mm. From the Sixola-River.
- similis*. **O. similis** Roths. Like *pronapides* (43 a), but the tegulae are brown like the patagia, the forehead not white, but dirty yellowish-brown, the pale basal area of the forewing is brown with 12 white spots (not whitish, speckled brown), and in the cell and at the costa there are 2 large white spots; the whitish apical spot, speckled brown, is absent, too; instead of it there is a small whitish spot $\frac{1}{4}$ before the apex at the costa. In the ♂ the white spots are smaller and the hindwings are darker. Upper Amazon.
- affinis*. **O. affinis** Roths. Likewise allied to *pronapides* (43 a); wings and body unicolorously smoky brown; the white areas at the base and before the apex only indicated by a white dot near the base and some buff subapical spots. Size of the preceding. Upper Amazon.
- funbris*. **O. funbris** Roths. (43 a). Dark sepia-brown, the forewings marked darker, the hindwings of a deeper black. At the base and before the apex of the forewing a fine white dot. Peru.
- brunnescens*. **O. brunnescens** Roths. Dark brown; recognizable by the white base of the hindwing. Forewing with a buff basal third in which there are reddish-yellow rings and spots; a buff spot marked reddish near the apex. Hindwings whitish yellowish-grey. Surinam and Upper Amazon.

O. atra *Rothsch.* Blackish-brown, thorax marked orange; forewing with a buff basal quarter and *atra*, buff subapical spot, both spotted reddish-yellow. Size of *pronapides*. Peru.

O. tessellata *Rothsch.* Size of *pronapides* (43 a); thorax lighter brown; in the forewing the basal *tessellata*, third is pale buff with reddish rings; it is defined by a broad, red-brown transverse band; rest of wing lavender-grey, near the apex a buff spot encircled by red-brown and striated reddish. Hindwings buff, margined dark brown. In the ♀ the speckling of the forewing is more whitish and more distinct. Upper Amazon and Peru.

16. Genus: **Carathis** *Grt.*

The 8 species forming this genus are very much alike, and their type of colouring strongly recalls that of most of the *Ochrodota*: over a pale yellow, dull ground-colour intense dark clouds are so profusely spread that they have almost entirely displaced this ground-colour on the forewing except small remainders at the apex, base and costal margin. Proboscis well developed; palpi bent up, but only very short, not reaching the forehead. ♂ antennae rather strong, doubly combed, more than half the length of the costa; thorax and basal part of abdomen densely and woolly haired. The venation of the forewing is just like in *Baritius*, but on the hindwing the subcostal despatches its branch behind the cell-end, not before it.

C. palpalis *Wkr.* (42 k) is the largest species. Thorax dark wood-coloured, marked bone-white *palpalis*, on the collar and shoulders. Forewing deep dark brown, the basal area, a crescentiform excision of the marginal area, a large oviform spot in the middle of the costa and minute spots at the middle of the proximal margin bone-white; at the base, and at the middle of the costa brick-red embedments; hindwings and abdomen dark yellowish-brown. From Jamaica.

C. byblis *Schs.* (42 k) from Mexico to South Brazil is very similar, but the brick-red embedments *byblis*, are absent. Abdomen above black, laterally orange, beneath greyish-yellow. Abdomen sooty black.

C. affinis *Rothsch.* (42 k) differs from *byblis* almost only by the abdomen being laterally and posteriorly *affinis*, coloured red, and by the bone-white spotting extending from the costa of the forewing in a bow to the white yellow basal area. Peru.

C. gortynoides *Grt.* from Cuba is almost exactly like *affinis*, but the marginal area is more narrowly *gortynoides*, spotted white, and the abdomen is laterally dull light brown.

C. ockendeni *Rothsch.* (42 k) has an entirely unspotted, brown median area, posteriorly red abdomen *ockendeni*, and dull hyaline hindwings. Caraboya.

C. australis *Rothsch.* on the contrary shows the chocolate-brown colour reduced to about $\frac{3}{4}$ of the *australis*, surface of the forewing, wedge-shaped, being narrowest at the proximal margin. Expanse of wings: 42 mm. Hindwings greyish hyaline. South Brazil.

C. klagesi *Rothsch.* from the Upper Amazon, has a pale buff thorax with a chocolate-coloured median *klagesi*, line; abdomen also light buff, posteriorly darker. Forewing covered with a whitish yellow, with a net of chocolate-brown lines, from the costa through the apical $\frac{2}{5}$ of the cell to the proximal angle; a broad, chocolate-brown band extends obliquely to the costa towards a narrower, irregular band. Smaller than *australis*.

C. peropaca *sp. nov.* (43 a) is quite dark, the forewings deep brown, the hindwings sooty black. *peropaca*. Only at the bases of the wings yet traces of small light spots. Also the abdomen is above quite blackened except the end showing orange-yellow colouring. Captured by FASSL on the Upper Rio Negro in Colombia.

17. Genus: **Neozatrephes** *Dr.*

The only butterfly belonging hereto is immediately recognizable by the very peculiarly distorted net of veins of the ♂ forewing. The cell is quite small, narrow and irregularly shaped by the discocellulars, the lowest of which extends almost in the prolongation of the median. The first subcostal vein rises soon after the cell-end, the 3rd, 4th and 5th branch off with a common footstalk before the transverse vein, and this footstalk is angled in such a way that its rise forms the continuation of the upper discocellular. The radials, therefore, appear to rise at the lower cell-wall and are uncommonly long. Otherwise the insect makes the general impression of a moderately large *Pachydota* or *Halisidota*.

N. telesilla *Dr.* (43 b). Head and thorax orange and brown, abdomen orange. Wings thinly scaled, *telesilla*, semi-transparent orange with rows of dark red dots; 6 rather broad bands with irregularly undulate margins are brown; the distal one exhibits a silvery white line. Hindwings hyaline yellow. Sarayacu (Ecuador).

18. Genus: **Nezula** Schs.

Here the ♂ forewings also show a distorted neuration; the upper median runs in the continuation of the discocellular; at its mouth it approaches the anal angle so very much that it reaches the border almost at the ingress of the lower median vein, thus creating an almost closed cell between the two median veins. The only species is a small, insignificant, greyish-brown animal with very narrow, pointed forewings, with a long distal margin, and small, almost circular hindwings.

grisea. **N. grisea** Schs. (43 b) is greyish-brown, with an orange-yellow head; hindwings slightly tinted bluish with a diaphanous stripe below the cell. Venezuela; Guiana.

19. Genus: **Dialeucias** Hmps.

Entirely resembles the preceding in the shape. Also the venation of the hindwing corresponds with that of *Hyperthaema*, on the forewing, however, the lower radial rises separately from the lower cell-end, whereas in *Hyperthaema* vein 4 and 5 are petioled. Two pale greyish red-brown species belong here.

pallidistriata. **D. pallidistriata** Hmps. Only the ♂ is known. Pale brown. Palpi orange with a black apex. Abdomen above dark brown, anus and venter yellow. Forewing somewhat reddish-brown; veins, cell and submedian fold with prominent light streaks; from the costa behind the middle, towards the middle of the proximal margin and towards the border above the anal angle, there extend faint traces of dull shades. Expanse of wings: 34 mm. Upper Amazon.

violascens. **D. violascens** Schs. has the head, thorax and forewings violettish-brown, abdomen and hindwings blackish-grey. The abdomen is beneath buff; on the forewing a median and a postmedian dark shade. 31 mm. Described according to one ♀ from French Guiana.

20. Genus: **Hyperthaema**.

Beautifully coloured butterflies with a strong proboscis and stout palpi bent up before the forehead. In the forewing the 2 first subcostal veins rise separately before the cell-end, the 3 others have a common pedicle. The antennae are doubly combed in both sexes. Except *albipuncta* the species differ very little from each other.

sanguineata. **H. sanguineata** Wkr. (= *cardinalis* Stgr., *orbicularis* Maass.) (43 c). Forewing of a beautiful dark red with 2 silvery white spots encircled dark. Hindwing blackish-brown with a whitish, somewhat diaphanous centre and base. Colombia to Peru and Bolivia. — **haemacta** Schs. (43 c) from Costa Rica is smaller and has much smaller white dots of the forewing, and the hindwing is quite sooty dark except 2 narrow light basal rays. Transitions to this latter form are before me from Huancabamba and (in FASSI's collection) from the Upper Rio Negro.

coccinata. **H. coccinata** Schs. Size of *haemacta* (43 c), similarly coloured, the distal white spot larger; the hindwing shows a white base and another white spot behind the cell. French Guiana; the type is in the American National Museum at Washington.

hoffmannsi. **H. hoffmannsi** Rothsch. Here only the basal third of the forewing is purple brown, the rest of the wing greyish-brown with purple veins. In the basal area there is a large, silvery white spot encircled by black extending to the proximal margin and sending a tooth distally; a second, smaller, silvery white spot at the cell-end. Hindwings blackish-grey; in the ♂ almost the whole disc, in the ♀ only the base is hyaline. 30 mm. Amazon, Rio Madeira.

ruberrima. **H. ruberrima** Schs. From French Guiana, established by SCHAU S; the type is in the National Museum at Washington. Somewhat smaller than *sanguineata*, the basal white spot round, at the base of the subcostal a black dot. There is no material difference from *sanguineata* stated.

albipuncta. **H. albipuncta** Schs. (43 c). Considerably smaller and with broader wings, almost like a ♀ of the following genus. Forewing yellowish red-brown, densely and finely striated. The two white spots of the preceding species are here very much reduced, the one at the cell-end to a minute, white-centred dot, the one in the median fold to a very small spot accompanied by accessory dots. Hindwings dark greyish-brown; abdomen dark pink. South Brazil.

21. Genus: **Stenucha** Hmps.

This genus was founded upon a damaged specimen of a small, quite dark brown species, which appears to be very rare, since it did not occur to me in the large collections from Mexico, which I saw. Palpi and proboscis are almost entirely stunted; in the forewing the 2nd subcostal vein is petioled with the 3rd, and the 4th with the 5th. The footstalk of the former bifurcation rises shortly before the upper cell-angle, that of the latter bifurcation at the upper cell-angle.

From the *Paracles* it differs by the transverse vein of the hindwing not being angled, before the middle of which the upper radial branches off. The forehead shows a dense, twisted hair-tuft.

C. dolens *Drc.* (43 a) is quite unicolorously blackish-brown, the body as well as the wings. But the *dolens*, only specimen known, being the type in STAUDINGER's Collection in the Berlin Museum, is without the abdomen. The hindwings show a dull bluish reflection. Mexico. — According to HAMPSON, the species is identical with *Hypomolis minca* *Schs.* and has been twice described by DYAR as *Zamolis noctella* and as *Ardanikta melas*, thus being distributed into 4 genera founded upon differences in the venation!

22. Genus: **Aemilia** *Ky.*

Proboscis strong, palpi showing upwards with a long basal and middle joint and stunted terminal joint. ♂ antennae doubly combed. Forewing without an accessory cell. On the hindwing the upper median is petioled with the last radial vein. The venation of the forewing is identical with that of *Carathis*, that of the hindwing only deviates by the subcostal vein, so that the butterflies were sometimes inserted in this genus, sometimes in another. About a dozen forms are known; in contrast with most of the common *Melese*, some *Aemilia* are decidedly rare.

A. roseata *Wkr.* (= *cinnamomea* *Bsd.*, *sanguivenosa* *Neum.*) (43 c) has a bright burning red thorax *roseata*, and forewing with a number of white discal spots arranged in groups, and a chain of light premarginal spots. Hindwings white, abdomen above purple red with darker shades. — In the form **significans** *H. Edw.* the discal *significans*, spots are more disorderly and partly confluent. From New Mexico and California to Colombia.

A. occidentalis *French* from Colorado shows the red of the forewing replaced by ochreous-yellow *occidentalis*, and the forewings so much darkened that the species bears a similitude to *Carathis peropaca* (43 a).

A. rubriplaga *Wkr.* (43 c). Dark brown, head and collar bone-white; on the forewing the basal half *rubriplaga*, and a large distal-marginal spot are likewise bone-white, netted dark brown; hindwings in the ♂ hyaline, in the ♀ smoky grey, towards the base rosey-red, like the abdomen. The colouring of this species is widely distributed in South America and is found in numerous Arctiids of various genera, such as *Hypocrisis minima* (42i), *Ochrodota pronapides* (43 a), *Carathis palpalis* (42 k), *Tesselota sertata* (42 f), in some *Halisidota* etc. From Venezuela and Colombia to Ecuador and Peru.

A. brunneipars *Hmps.* (44 l). Head, thorax and abdomen very dark brown, the head with a yellow *brunnei-* vertical dot. Forewing ochreous brown, densely striated dark brown, costa and proximal margin, except the *pars*, base, brown; marginal area obliquely from the apex to the lower cell-angle and from there to beyond the middle of the proximal margin dark brown; an elliptic discoidal spot dark brown; hindwings whitish, tinted brown, towards the margin darkened by brown. Also this scheme of markings recurs in certain *Opharus* and other South American genera. Size like the preceding species. Peru.

A. melanchra *Schs.* (44 l) is unknown to me in nature. Body dark brown; small white spots at the *melanchra*, vertex and base of abdomen. Forewings dark brown, striated still darker; a large patch at the cell-end, the border broadly from vein 7, and the proximal margin narrowly violettish-black. Hindwing dirty white with shaded brown margins. 38 mm. From Carabaya in Peru.

A. pagana *Schs.* (43 d) is a somewhat smaller species, the wings like in *melanchra* quite dark brown, *pagana*, but at the proximal margin of the forewing and base of the hindwing there is besides yellowish hairing; the thorax, however, shows orange-yellow stripes along the margins of the tegulae, and the abdomen is laterally orange-yellow. From Castro in Paraná (Brazil).

A. asignata *Hmps.* (43 d). Both wings quite sooty brown, only the hindwings more thinly scaled; *asignata*, thorax and abdomen marked yellow; the species is more slenderly built than the preceding. South Brazil.

A. testudo *Hmps.* (43 d). Considerably smaller, darker, the ♂ almost quite black, except a light costal- *testudo*, marginal spot before the apex and sometimes besides with a faint yellowish-brown brightening at the middle of the costa. The median as far as behind the cell-end yellowish. Peru and Bolivia.

A. chelyum *sp. nov.* (43 d) looks almost exactly like a very large *testudo*; but the hindwings are not *chelyum*, hyaline, but rather uniformly blackened sooty; the sulphur-coloured blurred patch at the end of the costal margin in the forewing extends to the apex, the one in the middle of the costal margin is larger, the whitish-grey colouring of the venter extends on the sides farther up towards the dorsum. From the Rio Songo in Bolivia and the Upper Rio Negro in Colombia.

- crassa*. **A. crassa** Wkr. (43 d) greatly resembles the preceding species, but the costal margin of the forewing is straighter, less convex, all the wings much more pointed, assuming more the shape of *Automolis*. Thorax at the sides and posteriorly of a bright orange-yellow, only in the middle brown; the costal spot at the apex of the wing forms a regular ellipse, the forewing shows a slight yellowish-red tint, the hindwing is not black, but hyaline. From Colombia to Peru.
- mincosa*. **A. mincosa** Drc. (= *mineosa* Rothsch.) (43 d). Size of *crassa*, lighter, the whole costal margin broadly, the median and submedian narrowly light yellow, the space between the latter somewhat hyaline. Hindwing hyaline, except the yellow margins; abdominal base rosy-red. Colombia to Peru.
- suffusa*. **A. suffusa** Jones (45 i) has the size and shape of *mincosa*, but the yellow costal stripe is absent, and before the border there are in the spaces between the veins blackish-brown sagittiform spots. Paraná in Brazil.
- fassli*. **A. fassli** Dgn. (45 h) is similar, pale ochreous-yellow, tinted orange, through the cell a dark longitudinal ray emanating at the border into an apical spot. Discovered by FASSL on the Quindiu.
- ambigua*. **A. ambigua** Stretch (= *bolteri* H. Edw., *spraeosiae* Drc.) (43 e). Margins and all the veins of the forewing scaled purple-brown, the spaces between diaphanous; abdomen purple-pink. From Colorado through Mexico as far as Central America, mostly rare.
- stuarti*. **A. stuarti** Rothsch. (45 h). Forewings doe-coloured, along the costa and median a blackish, longitudinal diffuse spot. Hindwing yellowish, with a hyaline disc; abdomen yolk-coloured. From the Lower Amazon.
- castanea*. **A. castanea** Jocey. Thorax and forewing chocolate-brown, the forewing with bone-coloured dots and small spots, hindwing blackish-brown with semi-diaphanous lighter parts in, behind and below the cell. Abdomen blackish-brown, at the dorsal base red-brown, on the sides rosy with dark lateral dots. Smaller than *stuarti*. Ecuador.

23. Genus: **Cissura** Wkr.

The genus in the distribution of colours somewhat recalls the Lithosiinae-genus *Hypoprepia* (33 i). The short palpi have an entirely stunted terminal joint; the antennae are also in the ♂ almost plain, i. e. with very short combs, whereby the genus can be easily distinguished from the preceding. On the wings the discocellular is neither angled nor bent in, but it obliquely closes the very short cell. Only 3 species are known.

- decora*. **C. decorata** Wkr. (= *parallela* Fldr.) (43 e). Forewings leaden-grey, with red margins and crossed by 2 red longitudinal streaks from the base towards the apex. Abdomen purple-red, hindwings brown. South Brazil, rare.
- plumbea*. **C. plumbea** Hmps. (= *decorata* Drc. n. Wkr.) (43 e) resembles *decorata*, the proximal margin and costa of the forewing is not red, but the two longitudinal stripes of the forewing are united in the apex. Besides the thorax is above marked brown. Peru.
- unilineata*. **C. unilineata** Dogn. (43 c). Forewings quite vermilion, only the narrow borders and a narrow longitudinal stripe not reaching the apex are greyish-black. Venter and abdominal end blackish. Bolivia and Ecuador.

24. Genus: **Melese** Wkr.

This genus, which consisted of but 10 species known at the beginning of this century, comprises 4 times as many to-day. In spite of the distinct difference in the course of the veins, I take the genus to be closely allied to the following, since certain differences in the venation can be traced back to secondary alterations in the shape of the wings. Beside a ♂ spot in most of the *Melese*-species the distal-marginal area of the forewing is bent round downward in such a way as we have not seen in any other genus of butterflies. This inverted border is above often harmoniously coloured with the under surface on which it lies. Antennae like in *Bertholdia* in the ♂ extremely short-combed, almost brush-shaped; palpi like there; the upper median vein of the forewing comes with the two lower radials from the lower cell-angle. Little is known of the larvae, but they seem to exhibit the usual Arctiid shape, uniform, tuft-like hairing on regularly arranged tubercles, in contrast with the torous, brush-like and pencil-like formations of the *Automolis*, *Eupseudosoma*, *Halisidota* etc. The butterflies are preponderantly coloured red, seem to prefer hiding in day-time, but are fond of coming to the lantern; many species are common in Tropical America, but in the north none reaches the United States, nor is the south of the Argentine Republic and Chile inhabited by any *Melese*. — The inverted forewing producing an entire alteration of the shape of the butterfly by being spread out, we reproduce of some species two male figures, the first with an inverted distal-marginal part, while on the second it is smoothly spread out.

M. peruviana *Rothsch.* (43 e, f). Recognizable by the very large yellow costal spot behind the cell-end and the intensely golden yellow distal marginal band of the forewing, which in the ♂, however, merges for the most part into the inverted part of the wing. Ground-colour of the forewing a bright violettish-red, intermixed with orange-red. Peru.

M. russata *H. Edw.* The ♀ shows a small white guttiform spot behind the cell-end of the forewing instead of the yellow costal spot, and the yellow at the border of the forewing is entirely absent; from Mexico. The ♂ is not described, but it presumably corresponds with the ♂ published by LORD ROTHSCILD as **drucei** (43 f), from Guiana and Peru, from the ♀ of which the *russata*-♀ is scarcely to be separated; the only difference consists in the small white spot behind the cell-end reaching yet the costa in *russata*, in *drucei*, however, not. — **monima** *Schs.* likewise greatly approximates the ♀ of *russata*, but the white spot of the forewing is still smaller. — **hebetis** *Rothsch.* (43 f) is a ♂ form in which the otherwise beautifully ruddle-red ground-colour of the forewing is bleached to a dirty yellowish-brown, the pink of the hindwing being replaced by a monotonous white. — The ♂ seems always to have a broad yellow distal margin of the forewing. The total species is also distributed over Colombia and Ecuador and apparently common in some places.

A. signata *Joicey* is somewhat larger than *russata*, forewings red-brown, tinted grey; from the base there extends below the costa a narrow purple stripe gradually passing over to the costa itself; on the median near the base a purple dot, on the wing besides other faded purple undulate markings and extinct red spots. Hindwings purple-pink, the middle whitish hyaline. In the ♂ the red spots of the forewing are brighter. Peru.

M. punctata *Rothsch.* (44 c). Antennae strongly combed. Head and thorax lavender-grey, washed over with an intense pink; abdomen light pink. Forewing light brown, before the last quarter of the wing a double yellow costal spot encircled by red; in the cell and disc 6 scarlet dots pupilled yellow, one between the inner-marginal vein and inner-margin. 22 mm. Ecuador. — **sixola** *Schs.* (43 h) is a larger form found in Costa Rica, but still in the south as far as Bolivia; here the inversion of the forewing in the ♂ is conspicuously lighter yellow; it has mostly scanty punctiform spots on the forewings. — In ab. **frater** *Schs.* also the spot between veins 5 and 6 is absent, only the spot between 2 and 3 being yet present.

M. nebulosa *Joicey* from Peru, is allied to *punctata* (44 c), but it has more greyish-brown forewings speckled pale pink in the disc; below the middle of the cell a yellow and red spot, an orange dot in the cell and a yellow stripe above the base of the proximal margin. Around them there are small, yellow-centred rings often touching each other; hindwings purple with yellow fringes.

M. laodamia *Drc.* (♀ = *cutheans* *Drc.*) (43 f). In this species distributed from Mexico to Venezuela and Colombia the yellow on the forewing of the ♂ is so much increased that it outweighs the red-brown ground-colour, and there are specimens before me, in which the yellow costal band extends behind the cell along as far as into the broad yellow distal-marginal band, which, however, is not always so distinct as in the figured example (from Misantla). In the ♀ the small costal band is moderately large, the yellow distal margin proximally dentate.

M. amastris *Drc.* (43 g). In the ♂ the extensively inverted distal-marginal part of the forewing shows no more yellow at all. The very bright ruddle-red forewing spotted miniate in the basal half often shows only behind the transverse vein a minute vitreous dot which is sometimes only the size of the prick of a needle and often quite absent. In the ♀ the small postmedian costal band is broad and hyaline, at the border only the fringes are in some places yellow. From Mexico to Peru and Brazil; not rare.

M. costimacula *Joicey*. A very large species of which, however, only the ♂ is known, from Choco in Colombia. Red-brown, with a violettish-grey hue over it, below the costal margin a purple stripe and below this an oblique, conical orange spot. In the cell and above the proximal margin small, feebler purple-spots, at the cell-end a yellow-centred purple ring. From the middle of the border to the apex an orange-yellow marginal band. Hindwings diaphanous white, tinted pink.

M. pusilla *Rothsch.* (44 c) is one of the smallest species with a darkened brownish thorax, whereas the head, collar and abdomen are coloured bright purple pink. Forewing particularly in the basal half bright purple pink; this half being separated from the marginal area by a brownish-violet chain of confluent spots, behind which there is a light dot before the middle of the margin. Hindwings uniformly purple pink, beneath whitish, tinted pink. Guiana and Upper Amazon.

M. columbiana *Rothsch.* (44 c) is established upon a single ♀ from Bogotá. Head and thorax greyish-brown, abdomen pink. Forewing yellowish greyish-brown, from the costa to vein 8 some darker shades round the cell; before the apical quarter of the wing a white hyaline streak, and behind the basal quarter of the forewing a white dot on the submedian; the forewing itself is indented above and below the apex; at the indentations the fringes are pink. Hindwings purple pink.

M. cruenta *Sepp* (= *binotata* *Wkr.*) (43 h). This is the largest *Melese* known; the ♀ attains an expanse of almost 50 mm. No distinct postcellular vitreous spot. The forewings are of a bright orange-red, densely suffused and watered with ruddle-red, so that only below the cell and in the basal area there remain miniate and orange-red spots. The hindwings are white in the ♂, beautifully pink in the ♀. — The larva

is black with blue tubercles exhibiting black bristles. Head black, marked orange. From Panama through South America to Paraguay and Peru. Apparently everywhere rare.

- underwoodi*. **M. underwoodi** *Rothsch.* is almost exactly like *cruenta*, but the forewing quite unicolorously red-brown, without the light discal spot, the marginal part in the ♀ (the ♂ is not described) almost unnoticeably lighter, the hindwings diaphanous whitish, faintly tinted pink, with almost red-ochreous margins. Described according to 1 ♀ in the Tring Museum. Costa Rica.
- dorothea*. **M. dorothea** *Stoll* (= *leucostigma* *Sepp*) (44 c) is but slightly smaller than *cruenta*, the forewing dull violettish-grey, in and below the cell spotted crimson-pink, at the same place as in *cruenta* there is a dull yellow (♀) or whitish (♂) hyaline spot. In the ♂ besides the inverted marginal part of the forewing is bright reddish-yellow. — Larva iron-grey, across the dorsum darker with a blackish-grey head and blue tubercles bearing straddling hair-tufts. It changes in an oviform web intermixed with hairs into a lustrous red-brown, oval pupa. Guiana, apparently rather rare.
- aprepia*. **M. aprepia** *Dgn.* (= *inconspicua* *Rothsch.*) (43 k, as *inconspicua*). Very much smaller than the preceding, on the greyish-red forewing a number of darker ring-spots: 2 basal ones, 2 antemedian ones, 1 cell-spot, 1 oblique spot below the median, 5 more behind the cell in the interspaces of veins 3 to 8. Hindwings pale ochreous-yellow. Guiana and Upper Amazon.
- chozeba*. **M. chozeba** *Dre.* (= *intensa* *Rothsch.*) (43 g). The fiery ruddle-red forewing of the ♂ has dark shades, particularly across the posterior part of the cell and before the distal margin, at the inverted place. The forewing usually also shows behind the cell traces of minute light spots which, however, vary extraordinarily. The species is distributed from Costa Rica to the south as far as Rio Grande do Sul in the east and Peru in the west. On the Volcano Irazu in Costa Rica the most common female form is a form with entirely unmarked forewings tinted violettish-brown; beside this form there also occur specimens with a distinct postcellular hyaline spot in both sexes, which I denominate **sesamus** *form. nov.* (43 g) and which are usually larger than typical *chozeba*.
- paranensis*. **M. paranensis** *Dgn.* (45 h) is easily recognizable by the angular apex of the ♂ hindwing. Forewings light brown; the base of the proximal margin is strewn with yellow and from the middle of the proximal margin there extends a ruddle-red stripe obliquely into the wing. A postmedian yellow spot is bordered with red. 38 mm. On the Upper Paraná.
- flavimaculata*. **M. flavimaculata** *Dgn.* (43 h). The yellowish-red forewing is at the costa darkened greyish, its distal part shaded with violettish-green, so that there remains only at the border a row of fiery-red internerval spots. In the middle of the cell, before the middle of the submedian space and before the apex golden yellow spots encircled by red. Ecuador.
- ocellata*. **M. ocellata** *Hmps.* (43 h) is smaller than the preceding, the forewing shaded with violettish-brown at the costal margin, border and proximal margin, so that there only remain irregular clouds composed of spots marked yellow and red, situate from the apex to the base of the proximal margin. Minas Geraes in Brazil.
- hampsoni*. **M. hampsoni** *Rothsch.* (43 h) is still smaller, one of the smallest *Melese* at any rate, with an expanse of only 25 mm; thorax and forewing entirely reddish-grey, only above the middle of the proximal margin a lobular spot coloured red and yellow; in and behind the cell of the forewing dark dots. Guiana and Amazon to Peru.
- leucanioides*. **M. leucanioides** *H.-Schäff.* (43 i). Very small, the greyish-red forewings in and behind the cell with some dark punctiform shades which are only faintly indicated in the ♀. Hindwings pink, in the ♂ hyaline except the margins. Colombia. — **erythrastis** *Dgn.* only seems to be a little larger, the forewing of a light greyish-brown, washed over with red except the middle of the proximal margin. Hindwing pink with a diaphanous centre. — **silvicola** *form. nov.* (43 i) is the form from the lowlands of Villavieencio in Colombia, somewhat larger, the forewing more uniformly and duller coloured with a dull dark nebulous band right through the forewing. — Guiana.
- innocua*. **M. innocua** *Dgn.* (44 c) is founded upon a single ♂ captured by A. H. FASSL near Cali in Colombia at an altitude of 2000 m. Presumably allied to the preceding, though larger, with yellowish-brown forewing being particularly in the basal part decorated with yellow spots marked with orange.
- quadrina*. **M. quadrina** *Schs.* (43 i) is larger than *leucanioides* which it otherwise greatly resembles, recognizable by one of the small black nebulous spots being in the middle of the cell and being larger and somewhat square. Before the last third of the forewing there are 3 white punctiform spots proceeding from the costa and forming a straight line. Costa Rica and Colombia.
- sordida*. **M. sordida** *Rothsch.* The ♂ is coloured almost like *quadrina*, but the characteristic spot in the middle of the cell and the 3 spots as small as the pricks of a needle below the costa are absent. The ♀ recalls *russata* or *drucei* (43 f), but the distal white punctiform spot is removed nearer to the apex, and another small white spot is situate near the base above the submedian. Peru.

M. incerta Wkr. (= *blanda* Dr., *surdus* Rothsch.) (43 k) is marked similarly to a *leucanioides* (43 i), *incerta*, and likewise with a somewhat straightly cut, though not inverted border of the forewing in the ♂. The colour, however, is not greyish-red, but fiery brick-red, the hindwing, particularly in the anal part, of a brighter purple. From Panama and the Island of Trinidad through Colombia and Venezuela to Espiritu Santo, Peru and Bolivia.

M. pumila Dgn. (44 c) is like a small *incerta* (43 k), with an expanse of only 19 mm. Forewings greyish-red, costal margin and fringes pink; near the base on the median a very small dot; hindwings yellowish, distally faintly tinged pink. French Guiana. *pumila*.

M. flavipuncta Rothsch. (43 i) approximates *pumila*, but it is larger; also in the ♀ there is a larger *flavipuncta*, yellow spot encircled by a dark colour on the submedian, near the base; the distal margin of the forewing is straightly cut off, the apex therefore very pointed. From Trinidad, Colombia and Surinam to South Brazil and Bolivia.

M. quadripunctata Rothsch. (43 k as *quadripuncta*) is like the preceding, larger; beside the small *quadripunctata*, yellowish submedian spot there are yet 4 reddish-yellow punctiform spots encircled by a dark colour on the disc of the forewing. Peru.

M. rubricata Dgn. (44 c) is immediately recognizable by the very bright red colouring of the fore- *rubricata*, and hindwings. In the disc of the forewing a group of about 10 to 12 small blackish punctiform spots. From French Guiana.

M. asana Drc. (43 k). The ♂ is at once recognizable by 3 small postmedian hyaline dots situate at *asana*, the costa like large pricks of a needle, below each other, but not exactly in a straight line as in *quadrina* (43 i), but in such a way that the middle one extends a little farther towards the margin. The ♀ may be similar to the ♂, though larger, paler, more unicolorous. Usually, however, it has a small hyaline-white band situate at $\frac{3}{4}$ of the costa, which is at the costa narrow, downward broader, or also somewhat crescentiform, running rather equally broad. The latter form is *albogrisea* Rothsch. South Brazil to Paraguay. — **petropolidis** *albogrisea*, *petropolidis*, Strd. from South Brazil is somewhat larger, above the proximal margin larger yellow spots.

M. postica Wkr. is like *asana* (43 k), but the forewing with smaller costal spots, and from the cell- *postica*, end to the proximal margin extends a dark nebulous streak. From Guiana and Venezuela to the Amazon and Peru.

M. castrena Schs. (45 i) is also like *asana* (43 k), slightly smaller, but the ♂ antennae are very finely *castrena*, serrate. On the yellowish-brown forewing a black cell-dot and one at the cell-end, near the base small purple-red rings on a buff ground, similar ones before the apex. Castro in Paraná (Brazil).

M. nigromaculata (44 c) Rothsch. Head and thorax light yellowish-brown, abdomen purple. Forewing *nigromaculata*, pale yellowish-brown, tinted with a bright red. At the cell-end a costal spot and a second spot below it; in the cell a black rectangle and a black dot near the base. On vein 3 a white spot and another one in the disc. Hindwings light pink. The border of the ♂ forewing is inverted as far as in *amastris*. Expanse of wings: 25 to 30 mm. Surinam to Central Brazil and Peru.

M. babosa Dgn. (43 k). The ♀ differs from the *asana*-♀ by the hindwing being grey instead of pink *babosa*, and by the irregular small costal band being several times shortly dentated on the forewing. The ♂ is unknown to me. South Brazil, Ecuador and Peru.

M. flavescens Joicey is somewhat larger than *babosa*; the forewings light red-brown, striated yellowish; *flavescens*, at the base of the proximal margin below the cell, before the middle and end of the cell somewhat yellow; the hindwings (in *babosa* blackish-grey) are here white, the inner-marginal area suffused with yellow; beneath they are white, tinted yellowish; the scent-spot on the forewing beneath brown. Misiones in Argentina.

M. klagesi Rothsch. (43 k) differs from *babosa* by the small, narrow, winding costal band and the *klagesi*, almost black hindwings. Surinam.

M. chiriquensis Schs. (43 k) differs from the two preceding by the shape of the small costal band *chiriquensis*, and by the hindwing being rosy-red in the basal half, sooty black in the distal half. Costa Rica and Panama.

25. Genus: **Bertholdia** Schs.

This genus contains about 20 very similar, extremely neat butterflies; there often occur transitions and all the species are characterized by a large vitreous spot extending from the middle of the costa almost to the apex, not reaching the border. The antennae are in both sexes bristly (in the ♂ with scarcely noticeable short cilia); palpi short, obtuse, bent upward. Proboscis strong; the ♂ with a small oval ♂ spot beneath at the base of the median fold; the venation like in the allied genera. The butterflies are mostly common, like to come to the light, but seem otherwise to live hidden. In the resting butterfly the thorax shows mesiodorsally a distinct median hair-quill.

- specularis.* **B. specularis** H.-Schäff. (43 l) is one of the largest species. The vitreous spot is strongly lobated towards the margin, surrounded by a distinct black, with a yellowish tone and only single vein-dots. From Mexico to Paraguay, nearly everywhere common. — **rufescens** Rothsch. are specimens from Peru, in which the grey colour of the forewings is more intensely toned red. — In the basal part of the forewing there are usually variable yellowish-red spots embedded.
- grisesens.* **B. grisesens** Rothsch. (43 l) is smaller, the forewings unicolorously slate-grey, the vitreous spot more white, but shaped as in **specularis**. But whilst the latter shows a variegated under surface of the forewing (a pink tinge in the basal area), the forewing is here grey beneath, with a small circumscribed red spot in the cell-end. Hindwings darkened grey (in *specularis* white). From Colombia to Paraguay and Peru.
- trigona.* **B. trigona** Grt. (43 l). Forewings above yellowish-red, the vitreous spot almost straightly cut off towards the apex. Hindwings purely white. Beneath almost the whole forewing is of a beautiful pinkish-red.
- steinbachi.* From Colorado and New Mexico to Costa Rica. — **steinbachi** Rothsch. (43 l) lying before me from Tucuman and Salta in N.W.-Argentina, has the forewings intensely tinged yellowish, and the vitreous spot is distally very feebly undulated. — Sometimes we find also in this species large yellowish-red spots embedded near the base of the forewing; this is ab. **rubromaculata** Rothsch. (43 m). — In **schausiana** Dyar (43 m) the vitreous spot has an obtuse tooth between veins 5 and 6, and the fringes of the forewings are speckled black. Mexico.
- rubromaculata.*
schausiana.
philoteria. **B. philoteria** Drc. (43 m) is the smallest species. Dorsum of abdomen posteriorly black, forewings wooden brown with a small, very lobate vitreous spot. Hindwings smoky grey, semi-diaphanous, with black margins. Under surface still darker than the upper surface. Costa Rica.
- semiumbrata.* **B. semiumbrata** sp. n. (43 m) is larger than the preceding, forewings lighter brown, hindwings uniformly smoky-grey. Abdomen above not black. Easily recognizable by the under surface, where the cell of the forewing is filled up with vermilion, whereas *philoteria* is beneath without any red except a hue on the proximal margin. 8 specimens (Coll. FASSL) in both sexes before me from Orosi, where it flies together with *philoteria*.
- braziliensis.* **B. braziliensis** Hmps. (= soror Dyar) (43 m). Forewings very similar to those of the preceding, though of a brighter red; hindwings white. South Brazil (Rio, Santos).
- myosticta.* **B. myosticta** Hmps. (= albipuncta Drc.) (43 m). One of the largest species, forewings dark violettish-brown. The vitreous spot begins already before the middle of the costa and exhibits a tooth mostly covered with numerous small dots, between the veins 4 and 5 on the forewing. Hindwings silky white, at the border coloured grey, proximal margin rosy. Beneath the forewings are blackish-grey with light veins and a red cell, the hindwing has a double longitudinal spot at the base. Abdomen above red, beneath white. Mexico to Brazil and Peru. — **crocea** Schs. (= aroana Strd.) (44 a) is larger, the inner-marginal half of the forewing more reddish-brown; the hindwings of a purer white, the proximal margin of a broader and brighter pink colour; beneath the base of the hindwing has only 1 instead of 2 black longitudinal streaks. — In **livida** form. nov. (44 a) the wings and abdomen above are almost entirely covered with yellow; also beneath the ground of the forewing is pale ochreous-yellow. From Lino in Panama; in Coll. FASSL. — **ockendeni** Rothsch. from Peru is almost like **crocea**, but the inner-marginal half of the forewing is of a bright yolk-colour and the abdominal end-black.
- livida.*
ockendeni. **B. fumida** Schs. (44 b) is only known to me from HAMPSON's figure copied here. Darker than **crocea** (44 a), particularly the dark smoky-grey ♀; the abdominal end with a subdorsal black spot. Forewing beneath quite dark smoky-grey, only in the ♂ traces of white above the proximal angle. Hindwing white with very little pink at the base of the proximal margin; the latter broadly suffused with smoky grey, in the ♀ also along the border dark smoky-grey. Costa Rica.
- fumida.* **B. flavidorsata** Hmps. (44 a) resembles the preceding species, particularly the vitreous spot is the same, but the forewings are more sepia-brown than reddish-or violettish-brown, and the abdomen and the proximal margin of the hindwing are yolk-coloured, the hindwings in the ♂ dark grey. Upper Amazon to Bolivia and Peru; not rare.
- flavidorsata.* **B. albipuncta** Schs. nec Drc. (44 a). Much smaller than the others, the hyaline spot is here particularly bright and shining, almost uniformly, parabolically bordered. The small white dot at the basal part of the median is often minute. Beneath not only the very bright hyaline spot of the forewing is opalescent, but also the surface of the hindwing shows an iridescent reflection. From Mexico through Central and South America to the south as far as Rio de Janeiro in the east and Ecuador in the west.
- albipuncta.* **B. detracta** sp. nov. (44 b) is by far the smallest species, the hyaline spot similar as in the preceding, but distally irregularly bordered. The under surface does not show any red; here the forewing is uniformly dark drab except the shining spot and a light patch above the proximal margin. There are several quite similar specimens before me from the Coll. FASSL, all from Muzo in Colombia.
- detracta.*

26. Genus: **Fasslia** Dogn.

This genus was established for a male butterfly unknown to me, captured by A. H. FASSL near Cali in Colombia in July. In HAMPSON's Catalogue of the „*Arctianae*“, however, the genus is not mentioned, so

that it appears doubtful whether it belongs to the Arctiids. It is characterized by bristly, erect palpi scarcely projecting beyond the head. Antennae with 1 pair of thick, short cilia at each joint. Posterior tibiae with a single pair of short spurs. Of the veins on the forewing 2 rises from the middle of the cell, 3 before the angle, 4 at equal distances from 3 and 5, 6 somewhat before the upper angle, 7 petioled with 8, 10 and 9; 11 separately. In the hindwing the anal part enlarged to a lobe ending into a point which exhibits some short bristles; vein 5 from 2; 3 and 4 are absent, 6 and 7 are fused.

P. hampsoni Dgn. „27 mm. Forewing above ochreous-yellow, crossed by a straight black line extending from the middle of the costa to the proximal margin just before the anal angle and ending in a black band which is narrow on the costal half, stronger at the rest of the border and widened in the apical region. Hindwing above black, the costal region as far as just in front of the apex, the central region as far as the marginal area and below vein 2 ochreous-yellow, the proximal margin of the lobe provided with long hairs, straw-coloured. Fringes black. Under surface of forewing like above, but the black transverse line proximally duller. Under surface of hindwing quite ochreous-yellow except some black at the base and a narrow black band at the apex and border. Fringes black; palpi, antennae, head and under surface of the body black with some white hairs on the head. Feet black; hips and inside of femora striped white; abdomen yellow. From Mount Socorro 3400 m.“ *hampsoni*.

27. Genus: **Robinsonia** Grt.

Shape and size very much like the *Bertholdia*, but the forewings still more pointed. The discocellular of the forewing not angled as it is there, but very oblique; in the hindwing vein 5 is absent. — Nearly all are white butterflies, their forewings often margined dark and crossed by similar bands, without any real shining parts. They are distributed from Mexico to South Brazil in a series of partly rather similar species. In day-time they are apparently never met with, but they like to come to the light. Many species are, moreover, rare.

a) Forewing broad with a round apex.

R. evanida Schs. (44 b). Wings almost quite monotonously snow-white, in the disc and submedian space of the forewing and in the disc of the hindwing hyaline patches, abdomen orange. Santiago de Cuba. This species has rather broad wings. *evanida*.

R. formula Grt. This species, likewise from Cuba, has also rather broad wings. The forewing is brown with a large, spindle-shaped, white spot below the cell, almost flowing together with a similar spot above the anal angle. From the apex a white oblique band extends towards a large white triangle beginning at the cell-end. Hindwing white with brownish fringes and a yellowish tinge at the anal angle. Rare. *formula*.

b) Forewing stretched with a sharper apex.

R. prophaea Dogn. (44 b). All white, with only very narrow, yolk-coloured costal margin of the forewing and yellowish abdomen. Peru. *prophaea*.

R. sabata Drc. (44 b) is much larger, white, the costal margin of the forewing and mesothorax dark brown. Middle of abdomen yolk-coloured with small white median spots. Honduras. *sabata*.

R. marginata Roths. (44 c) is almost like a large *prophaea*, but in the forewing beside the costa also the distal margin is narrowly yellow. Guiana. *marginata*.

R. flavicarpus Dogn. (44 d). One of the smallest species; white with an orange abdomen; on the forewing the costa is sooty brown, so is the distal margin; but this distal band emanates proximally in irregular teeth. Guiana, discovered by LE MOULT. *flavicarpus*.

R. dewitzi Gndl. (= *grotei* Schs.) (44 d) is very typically marked: forewing white with brown margins; a brown oblique band unites the middle of the costal margin with the marginal band at the anal angle. The butterfly is common, wide-spread, and varies somewhat. In Mexican specimens the distal white spot extends into the apex and the oblique band is slightly curved. Similar specimens are said to come from Cuba (= *dewitzi* Gndl.). Specimens from Merida in Venezuela are particularly large and have long and pointed forewings; we figure such a specimen. *dewitzi*.

R. punctata Roths. (44 d). Here the marginal band of the forewing is only yet dull and incoherent, and at the place where the oblique band flows into the brown at the anal angle, there appears another white spot. Abdomen posteriorly orange-red. Mexico; rare. *punctata*.

R. similis Roths. (44 d). In this species from Trinidad also the brown band vanishes at the proximal margin and anal angle. Thereby a superficial resemblance is produced in the colouring with that of *Turuptiana lacipea* (39 l). *similis*.

- deiopea*. **R. deiopea** Drc. (44 d). From Honduras, has yet the scheme of markings of *grotei*, but at the apex a part of the white is strangulated as a large apical spot.
- flavomarginata*. **R. flavomarginata** Drc. (44 d). Forewing with a broad brown costal-marginal stripe filled with orange. The distal half of the forewing is quite nut-brown, with a large, white oval spot behind the cell and smaller antemarginal spots. Hindwing with a broad brown margin interrupted in the submedian fold. Colombia.
- rockstonia*. **R. rockstonia** Schs. (44 e). Costal stripe of the forewing broad yolk-coloured, the margins of the forewing otherwise nut-brown, similar as in the preceding, but the oblique stripe from the cell-end to the distal margin only indicated by the brown veins. Hindwing without a brown marginal band. From Colombia to Guiana. In typical specimens (from Essequibo) the costal-marginal stripe of the forewing is more golden-yellow, the lower part of the cell filled up with a smoky brown, the marginal band of the forewing projecting proximally at the median veins, the apical spots smaller, more distinct and of a purer white than in the figured specimen from Villavicencio (Colombia, Coll. FASSL).
- lefaivreii*. **R. lefaivreii** Schs. (44 d). The yellow costal stripe of the forewing narrower, the whole cell of the forewing nut-brown, which colour is continued in the direction of the oblique transverse band occurring so often in the *Robinsonia*, as far as the middle of the disc. Hindwings preponderantly grey. Described from Rio de Janeiro, where, however, the species must be rare.
- irregularis*. **R. irregularis** Rothsch. (44 e) is quite similar, but the white of the disc of the forewing is narrower, the yellow costal stripe scarcely noticeable, the hindwings white. From Cuyabá (Matto Grosso).
- polyplagia*. **R. polyplagia** Schs. (44 e). Forewings yellowish-brown, traversed by dark veins and streaks between; 1 silvery white spot each is below the cell, behind it and above the anal angle; two smaller, oval ones at the apex. Hindwing white with a dirty brown inner-marginal shade. From Venezuela. — The form **transducens** *form. nov.* (44 e) shows a complete row of silvery white antemarginal rays; from Costa Rica; it thereby forms a transition to **multimaculata** Rothsch. (44 e) from Peru with a much larger silvery spot in the disc, a more steeply placed oblique band across the cell-end and a large silvery spot in the end-part of the cell of the forewing. — The species is apparently distributed over a great part of South America and the southern parts of South America, but everywhere rare.
- catasticta*. **R. catasticta** Hmps. (44 e) is much smaller than the preceding; the 2 apical spots are confluent to one, so that 3 silvery white spots of decreasing size follow each other from the base of the forewing to the apex; below the middle spot there are 2 more, a dot before the middle of the border as well as the base and proximal margin of the forewing and the whole hindwing are white. Peru.
- sanea*. **R. sanae** Drc. (44 e). Spots of forewings similarly arranged as in *catasticta*, but duller, very much enlarged and increased. Costa Rica to Colombia. Rare.
- banghaasi*. **R. banghaasi** Rothsch. (44 f) on the contrary shows the white spots reduced except very minute punctiform spots below and behind the cell as well as before the apex; otherwise the whole forewing and the apical part of the hindwing are dirty brown. From Matto Grosso.
- suffusa*. **R. suffusa** Rothsch. (44 f). In this form and the following the white spots of the forewing are not pure nor are they sharply defined from the dull brown ground of the wing, but the white colour is spread in long diffuse patches across the whole forewing except the proximal margin, costa and border. From Fonte Boa on the Upper Amazon.
- morula*. **R. morula** Drc. (44 f). In this species the white of the forewing is reduced to a blurred, longitudinal, diffuse patch extending from the base towards the apex; it is interrupted before the apical fourth; hindwings in some places darkened; abdomen above grey with a row of yellow dots. Peru and Bolivia.
- klagesi*. **R. klagesi** Rothsch. (44 f). Forewing nut-brown with a broad, white longitudinal stripe through the middle, somewhat bent downward, from the base almost to the apex. Hindwings white, abdomen yellow. Colombia and Venezuela.
- longimaculata*. **R. longimaculata** Schs. greatly resembles the following. The brown forewings with dark veins show a row of oblong, white, oval radiate spots from the apex to the lower median vein; in the submedian space there is a white stripe, thickened in the middle, from the base to the border above the anal angle. Abdomen brown with a golden-yellow dorsal stripe. Described from Joinville in Brazil.
- boliviana*. **R. boliviana** sp. n. (44 f) is very much like the preceding, but instead of the oblong white wedge-stripe filling up the whole submedian space of the forewing there is here a white oval below the middle of the cell and a minute white, darkened spot near the anal angle. The abdomen is above quite yellow with small, white dorsal dots. Rio Songo; discovered by FASSL; type in his collection.

28. Genus: **Prumala** Schs.

To this genus about 30 forms are reckoned, partly very much deviating from one another in the habitus. This is defected by some species showing distinct resemblances to species of other genera, for which reason

some have been described as *Automolis*, *Idalus*, *Eucyrtia*, *Elysia* etc. The fact that the *Prumala* resembling butterflies of other genera are no models, but imitations, is proved by the different *Prumala*-forms showing no transitions to one another, whereas their double images fit well to the casual genera in the marking and habitus, often only representing links of whole chains of similarly marked species. On the whole, the genus makes the impression of a very artificial one, out of which, however, some natural groups such as those of *P. optima*, *P. tessellata* etc. may be taken out, which, however, are not united with each other by connecting links. From the closely allied *Idalus* (with which some *Prumala* are more closely allied than with each other) they differ by the short bifurcation of the subcostal on the hindwing, which ends unforked into the margin in the *Idalus*, so that one of the radials is absent (being fused with the subcostal). The body is mostly cylindrical, sometimes clumsy, the wings without any particular deviations in the shape, sometimes more pointed, sometimes broader, the hindwings never so rudimentary as in some *Idalus*. The larvae are entirely unknown, presumably, however, not homogeneous; some are probably normal, uniformly haired bear-caterpillars, whereas others may perhaps exhibit the peculiar hair-dresses of the *Automolis*, *Halisidota* or *Eupseudosoma*. The imagines like to come to the light, but are otherwise rarely met with.

P. fogra Schs. (44 f) differs so little from the species described last of the preceding genus that it *fogra*. has been described as *Robinsonia*. Wings white, the margins of the forewing emitting from outside sooty brown, irregular spots or shades. Hindwing diaphanous white with a dark grey proximal margin. Abdomen orange, the basal part with a blackish-brown dorsum showing small white dorsal dots. Venezuela.

P. saturata Wkr. (= praetexta Fldr.) (44 g). The species shows the colouring of *Automolis*-species *saturata*. from the *metallica*- and *packardi*-group (50 e). Body yolk-coloured, head, mesothorax, 2nd ring and anal half of the abdomen black, in some parts with small sparkling blue spots. Forewing with a yellow band below the cell and a striated marginal part, hindwings eostally yellow, anally black. In the northern parts of South America, on the Amazon and in Colombia; apparently widely distributed, but not common.

P. ameoides Btlr. (44 g) resembles certain *Automolis* so much that it was described as such. Body *ameoides*. similarly coloured as in *saturata*, wings bright yellow, forewing with a brown border, proximal margin and oblique transverse band, hindwing with a brown distal margin. From Venezuela to Ecuador in some parts not rare, for instance near Merida in Venezuela and on Mount Tolima in Colombia.

P. flavoplagiata Roths. (44 g) copies the image of *Idalus flavoplagia* (45 e) or *Automolis persimilis flavoplagia* (51 h). Body yellow with a black, sparkling blue apex; forewing brown with a large, yolk-coloured costal triangle, hindwing brown, with yellow at the proximal margin. Colombia. *ta*.

P. griseipennis Roths. (44 g) resembles numerous *Phaegopterini* from the genus *Automolis*, particularly the more one-coloured specimens of *A. docis* Hbn. (51 f). Greyish-brown; a stripe-like, light patch separates the darker basal part of the forewing from the lighter, narrower marginal part. Abdomen above in the basal half red, in the anal half blackish-brown with sparkling blue scales. Beneath the middle of the venter and the cell of the hindwing of the ♂ are red. Colombian ♂♂ show besides above a bright patch in the cell of the forewing, which is apparently absent in specimens from the Amazon *). *griseipennis*.

P. tessellata Schs. (44 g). Fresh specimens are of a beautiful green, with large brown spots, the largest of which are on the costa; an antemarginal chain of small streak-spots. Hindwing dark brownish-grey, round the cell a light patch tinged yellowish-pink, in which there is a square particularly distinct beneath. From Costa Rica to Colombia; the figured specimen from Muzo. — **subtessellata** Roths. (44 g) is the form from Venezuela, with very bright sap-green forewings and unicolorous, black hindwings; instead of the chain of streaks before the margin of the forewing a row of dots. *tessellata*. *subtessellata*.

P. muscosa Schs. (44 h) which is before me only in a damaged specimen from the Volcano Irazu (Costa Rica, 1200 m, Coll. FASSL), has likewise green forewings, but instead of the large brown spots of the forewing in *tessellata*, there are here rows of black transverse streaks and sagittiform spots. Smaller than the preceding. *muscosa*.

P. herbosa Schs. (44 h). ♂ light green, on the forewing violettish-brown markings, i. e. some stripes in the disc standing rectangularly on each other, an oblique line thickened behind the cell-end and at the proximal margin, before the marginal part, a dot in the cell-end and an antemarginal row of dots. Hindwing quite pale and diaphanous whitish-green with a dark cloud near the anal angle; dorsum of abdomen red. Costa Rica. — **underwoodi** Roths. (44 h), likewise from Costa Rica, of which a great number of rather variable specimens are before me from Orosi, shows the brown markings thickened and partly filled up with green. — **foliosa** form. *foliosa*. *nov.* (44 h) from the Rio Songo in Bolivia has, on the contrary, the brown streaks thinner, and the antemarginal row of dots on the forewing has almost disappeared; above all, however, it differs by the dorsum of the abdomen being blackish-brown, not red. — The ♀♀ are of a much deeper green than the ♂♂ and exhibit only incoherent dots of the brown markings. The species seems to be rather common. *herbosa*.

* Judging from the figure (Novit. Zoolog. Vol. XVI., t. 6, fig. 7), since there are no specimens from the Amazon before me.

- alinda*. **P. alinda** Dyar (44 h). Whilst the preceding species approached some *Turuptiana*, we find in this species and the following ones resemblances to *Idalus* or *Antaxia*. — *alinda* has almost the same marking of the forewings as *herbosa underwoodi*, but on a bright yellow ground, and the hindwing is pink with an ante-marginal row of dull dots. Abdomen bright red. Mexico; discovered by ROBERT MÜLLER.
- tophocampoides*. **P. lophocampoides** Fldr. (= *ipsea* Drc., *fulminans* Rothsch., *tolimensis* Rothsch.) (44 h) has a similar marking in purple pink and brownish tints on a bright yellow ground, which, however, is besides starred with numerous pink dots being particularly abundant at the basal part and often confluent there. The species is distributed from Mexico to Peru and South Brazil and varies exceedingly, but judging from the material before me more individually than geographically; thus the brighter yellow specimens with darker markings (*fulminans*) both in Venezuela and Peru, the duller specimens (*ipsea*) both in Mexico and South Brazil. The species is in some places not rare.
- palmeri*. **P. palmeri** Rothsch. (44 i) from West Colombia, has yellow forewings with a large, purple-brown spot bordered with scarlet, in the proximal area, extending from the base to the proximal angle and the middle of the cell, and the distal margin of which is curved and sends a spur across vein 2; behind the middle of the proximal margin a spot, and small spots in the submedian fold. Also round the cell-end there are minute spots and a purple-brown luna before the apex. Hindwing pale yellow, the proximal half faintly tinted purple pink.
- maculicincta*. **P. maculicincta** Hmps. (44 i). Instead of being very bright yellow as in *lophocampoides*, the forewings are here dull honey-coloured with numerous grey spots encircled by brown, being arranged in about the same way as in the preceding species. Hindwing dark greyish-brown, towards the base darker grey; body dark yellowish-brown, head and collar lighter yellow. South Brazil, undoubtedly rare.
- jamaicensis*. **P. jamaicensis** Schs. Size and shape of the preceding, but the ground-colour of the forewings is red-brown towards the base tinted olive; the ring-spots are scarcer and some have whitish pupils; hindwings light purple, like the undersurface. Jamaica.
- indistincta*. **P. indistincta** Rothsch. (44 i). Smaller, forewings pale honey-coloured with very scarce, vanishing, brownish punctiform shades; hindwings white, with a very faint yellowish-pink tint. Known from Chiriqui (Costa Rica) and Paraguay, probably distributed through the whole of South America, but rare.
- sulphurea*. **P. sulphurea** Joicey is unknown to me. Somewhat larger than *indistincta* (44 i), thorax and forewings light greenish-yellow; a small dark spot near the base, below the cell a violettish-brown spot spread with purple and surrounded by brown; a similar spot in the middle of the cell; a row of brown, small rings filled up with violettish-grey before the marginal part, of which the spot on the submedian fold is larger; a similar row from near the cell-end to the submedian and 2 dark oblique spots separated by a purple streak from the apex; an antemarginal row of minute rings. Hindwings white, towards the proximal margin tinted pale red; abdomen white, tinted pale red-brown. Peru.
- suanus*. **P. suanus** Drc. (44 l) has the size of the preceding, but the forewings are of a bright yellow and have a white costal margin; the small spots are encircled by purple or violet and filled up with whitish, the oblique row before the distal quarter begins with a triangular costal spot before the apex and ends in the ♂ in a conical spot at the proximal margin; the hindwings are diaphanous white. Costa Rica, Colombia, Venezuela.
- aryllis*. **P. aryllis** Schs. (44 i) is the largest *Prumala* known; sulphurous yellow, in the distal half the forewing has jet-black vein-streaks; similar ones, bordered by white above, are situate above the proximal part of submedian and subcostal. — The butterfly by its marking greatly resembles quite a number of Arctiids common in South America, e. g. *Pachydota striata* Dgn., *nervosa* Fldr., *Ischnocampa nigrivena* Schs., from which, however, it differs by the veins and the shape of the wings, as well as by the dorsum of the abdomen being often black there, whilst in *aryllis* it is dull honey-coloured. Venezuela.
- albicollis*. **P. albicollis** Fldr. (44 i). Thorax and the basal $\frac{2}{3}$ of the forewing violettish-brown, the apical third light yellow with 4 subapical, alternately placed, dark punctiform spots. Collar conspicuously white, abdomen and hindwings purple-pink. From the Amazon.
- ochrida*. **P. ochrida** Schs. (44 i). Body brick-red with a yellow head and collar; forewings honey-coloured, but profusely covered with dark-brown and purple-brown clouds and bands. The wing is crossed by dark veins and between them there are purple-brown antemarginal dots. Fringes speckled. Hindwings yellow, in the anal half radiantly tinged pink. South Brazil.
- pyrostroma*. **P. pyrostroma** Dgn. (44 i). Thorax violettish-brown with a bone-white collar, head light with a red vertex. Forewings honey-coloured, costal and basal parts suffused with violet; at the cell-end a group of dark dots bordered with red, and through the submedian space there extend 3 violettish-brown transverse bars. Distal part of the forewing purely honey-coloured, below and in the apical part disperse brownish dots. Abdomen and hindwings purple. French Guiana.

P. optimus *Btlr.* (44 k). Thorax and forewings traversed by a violettish-brown network in such a way that there remain numerous honey-coloured cells pupilled scarlet. Abdomen darker, hindwings lighter rosy-red. In the typical form from the Amazon the network is rather uniform; only obliquely before the apex and above the proximal margin there extend somewhat thicker cords. — In **intensa** *Rothsch.* (44 k) these latter two cords are about 2 or 3 times as thick as in specimens from the Amazon; from Guiana. — In **similis** *Rothsch.* (44 k) the network is twisted somewhat differently, the intermediate threads more distinct, the hindwings lighter; Guiana and Amazon. — **attinis** *Rothsch.* (44 k) shows yet 2 dark clouds before and behind the middle of the costa; from Brazil and Peru, — and **ockendeni** *Rothsch.* (44 k) is the same, though larger; it shows besides brown marginal spotting below the apex and has whitish instead of purple-pink hindwings; from Peru. — It seems to me to be doubtful whether all these forms can be considered as species, as was assumed. The butterflies are in some places common.

P. hieroglyphica *Schs.* (44 k) is coloured like the preceding, but the net-work consists more of straight, brown lines cutting the dark veins, than of undulate or dentate bands; at the base of the proximal margin a large, oval, red spot. French Guiana. Known to me from the description and the figure in HAMPSON's Catalogue copied here.

P. ignipicta *Hmps.* (44 k). Thorax and forewings violettish-brown, collar as well as spots at the base and proximal margin reddish-yellow; hindwings light pink, abdomen purple-red. From the Tijuca near Rio de Janeiro, certainly very rare, as it has not been found there by many collectors.

P. nigranalis *Schs.* (44 k). Body quite yellowish-brown with a darker apex of the abdomen; forewings unicolorously chestnut-brown, hindwings light yellowish-brown. „South East Brazil“.

P. jalapa *Drc.* (44 l). Unicolorously ochreous-yellow with lighter hindwings (except the margins); in the ♀ the dorsum of the abdomen is posteriorly spotted reddish-yellow. Mexico.

30. Genus: **Idalus** *Wkr.*

Whilst the white *Robinsonia*, the red *Melese*, and the *Bertholdia* being decorated with a postmedian sparkling spot were very natural genera, in which there could at most only arise a doubt whether some were merely subgenera, we are opposed in this genus, in a similar way as in the *Prumala*, by a group exhibiting resemblances to several other genera, its species having been described sometimes as *Amaxia*, sometimes as *Automolis* by SCHAUS, LORD ROTHCHILD and others. We here also follow HAMPSON's disposition applied in his excellent Catalogue and having since been chiefly adhered to by the other authors (STRAND, DYAR). The genus, accordingly, comprises about 40 species, all of which are confined to Tropical America; no species reaches the United States; they preponderantly inhabit the hot parts of South America. The antennae may be doubly combed and also serrate dentate, and provided with ciliary tufts. The venation, as is often the case in the Arctiids, is little characteristic, particularly that of the hindwings varies rather considerably owing to the changes of its shape, scent-organs and distortions. The proboscis is always active, the head woolly haired, with short, erect palpi, the thorax densely haired like a fleece, the abdomen generally with glaring colours. On the forewing the anterior discocellular is entirely absent, the cell is of somewhat more than half the length of the costa and obliquely cut off; the 1st subcostal vein rises close before the cell-end; the venation of the hindwings is sometimes very much reduced by scent-organs. As to the larvae nothing has become known to me. The imagines mostly exhibit variegated, some even metallic colours, but they nevertheless seem to be decidedly nocturnal animals, since those that I chanced to observe, did not come to the light before 9 p. m. — The different groups of forms of the collective genus *Idalus* resemble in their habitus species of other genera, a fact often met with in the American region. Thus *tetrodonta* and *affinis* resemble *Amaxia pyga* (45 e); *agastus* and *agricus* the *Automolis critheis* and *herois* (49 k); *J. xanthia* resembles *Automolis orbona* (50 g), *J. neja* is like *Amaxia pardalis* (45 e), *J. flavoplaga* like *Automolis persimilis* (51 h) and with the latter like *Prumala flavoplagiata* (44 g), and some of these resemblances may be founded on real affinities. Thus *J. viridis* *Drc.* I consider to be nothing else but a form of *Chloroda rufoviridis* (39 i) with distally paler hindwings.

I. tetrodonta *Dgn.* (44 l). One of the largest and most beautiful *Idalus*. The purple-brown basal half of the forewing, bordered by red, is obliquely defined towards the yellow distal part decorated with fine nebulous dots and with a characteristic, centrally strangulated apical spot. Hindwing white, anal third pink. Thus an assortment of colours is produced, often recurring in Tropical America, as we find e. g. in *Neonerita syriassa* (45 h), *haemasticta*, *Epimolis zatrephica*, *Antaxia meridionalis* etc. Venezuela. — In the form **anodonta** *form. nov.* (44 l) from the Rio Songo in Bolivia the purple-violet basal area does not send any teeth into the yellow of the marginal half, the apical spot is more slender, the middle of the border of the hindwing sooty black, the under surface more yellow. A form very much like this is also before me from Colombia, from the Pacho.

- affinis*. **I. affinis** Rothsch. (45 a) entirely resembles the preceding, but the violettish-brown parts of the forewing are more compact: the apical spot is curved like a crescent, the hindwings of a pure white. Colombia, Peru. In Peruvian specimens the brown apical spot is more slender than in the figured specimen from the Pacho.
- rufobasalis*. **I. rufobasalis** Rothsch. (45 a). From the Upper Amazon: here the brown apical spot is absent; otherwise like *affinis*.
- catenata*. **I. catenata** Schs. (45 a). The large, purple-violet basal spot of the forewing is here so strongly intermixed with the yellow ground-colour that it is dispersed into single, small, brown clouds. Of the small, brown, punctiform spots in the yellow distal part of the forewing mostly the proximal one of those situate behind the transverse vein is larger and somewhat flown out. More to the south, Bolivia, South Brazil.
- neja*. **I. neja** Schs. (45 a) from Guiana. The whole forewing is intermixed with smaller and larger guttiform spots; hindwing dark sooty, in the anal part lighter.
- laurentia*. **I. laurentia** Schs. (45 a). The small spots are more uniformly distributed over the whole forewing, so that the colouring approaches that of *Phaeomolis lepida* and *Amasia pardalis* (45 f), but in *laurentia* there are instead of brown punctiform spots, distinctly marked small black rings. Guiana.
- favillacea*. **I. favillacea** Rothsch. (45 a) is marked almost exactly like *catenata*, but the forewings are paler, the spots much smaller, more diffuse, in some places almost entirely extinct: the hindwings are dark sooty-grey. Surinam.
- reticulata*. **I. reticulata** Rothsch. (45 a). Ground-colour diaphanous whitish, the small dark spots dirty yellowish-grey, irregularly arranged like a net; in the basal and marginal parts of the forewing and at the middle of the border in the hindwing more densely congregated. Upper Amazon.
- rosea*. **I. rosea** Schs. (45 b). Through the bright yellow forewings being densely covered with small red-brown drops there extend violettish-grey macular bands, particularly before the marginal part and before the middle. Venezuela and Colombia; the butterfly is common and widely distributed; small and very red specimens are found near Muza; a large and beautifully variegated form in which the blackish spots of the forewings are smaller and darker, is before me from Pacho; owing to the veins distinctly streaked red I denominate it **strigifera** form. nov. (45 b). — The species varies very much.
- rubens*. **I. rubens** Schs. (45 b). More slender and with narrower wings than *rosea*; the small streak-spots between the red veins of the forewing are prominently black; hindwing hemochrome, with a white, oval male spot below the costa. Guiana.
- irrupta*. **I. irrupta** Schs. (45 b). Instead of the black streak-spots there are between the red veins distinctly black small rings; the costa of the forewing is broader brown. Otherwise like *rubens*. Guiana.
- punctata*. **I. punctata** Rothsch. (45 b). Forewing and thorax dark brown, sometimes more coarsely, sometimes more finely speckled yellowish-white; abdomen dark brown; hindwing brown, in the middle lighter or also quite whitish, only with dark speckled fringes. Strongly recalls certain *Opharus*-species, such as *sestia*, *intermedia*, flying in the same district. Peru.
- costaricensis*. **I. costaricensis** Rothsch. (45 c) almost looks like a small, stunted form of *affinis* (45 a), but the 3 small subapical spots forming there the dark apical crescent, are here so small that they do not touch each other. It was described as a *Neaxia*. Costa Rica.
- doncasteri*. **I. doncasteri** Rothsch. (45 c). On the sulphureous forewing there is only a premarginal row of red-brown rings, with larger, brownish nebulous spots before the apex and proximal angle. Hindwings semi-diaphanous whitish-grey, anal part pink. The ♀ has brownish dots instead of the small rings. Venezuela.
- citrarius*. **I. citrarius** Dgn. (45 c) is closely allied to *doncasteri*, but the ♂ forewing has here a violettish-brown oblique stripe bending round on the submedian fold and turning then towards the base of the wing. There usually also runs a spur-like continuation from the flau towards the anal angle. The ♀ has only very fine, small black dots on the forewing, it is also without the rosy-red reflection exhibited in the ♂ on the dorsum of the abdomen and in the anal part of the hindwing. Colombia, Ecuador, and Bolivia.
- pandama*. **I. pandama** Drc. (45 d) is as large as the preceding, the wings are likewise yellow, but by a rather uniform, dark striation it somewhat resembles a *Halisidota*, in which genus it was also described. The somewhat paler yellow hindwing shows towards the margin large, dull black internerval spots. Ecuador, Bolivia.
- lutescens*. **I. lutescens** Rothsch. (45 c). Body and wings unicolorously unmarked light yellow, only before the apex the costa is a little brownish. Peru.

I. xanthia *Hmps.* is smaller, unicolorously orange-yellow, only the 4 last abdominal rings are black with lustrous blue spots, and the border of the hindwing is slightly brownish above the anal angle. Venezuela. — The species resembles numerous other Aretiids from the same district, such as *Automolis bonora sulfurea*, *pauperis* (50 h) etc.

I. flavobrunnea *Dgn.* resembles *xanthia*, larger, likewise orange-yellow with a black abdominal apex: but the whole apex of the forewing is here pale red-brown. This colouring extends from the apex of the wing almost to the cell-end, and from above the anal angle there runs a thick ray filling up the whole space between the median veins as far as the lower cell-wall. Peru.

I. flavoplaga *Schs.* (45 e) also approximates by its exterior numerous other Aretiids, such as *Automolis priscilla*, *persimilis* (51 h) etc. Here the whole forewing is dark brown except a large, costal, yellow triangle and a stripe above the proximal margin. Through the dark ground of the forewing there run lighter veins: hindwings pale yolk-coloured. Guiana.

I. pseudameoides *Rothsch.* (45 c). The exterior of the ♂ is so very similar to that of *Prumala ameoides*, that the two species might easily be mistaken. The *Idalus*-species, however, is easily discernible by the scent-organ resting on the costal part of the hindwing like a discoid pad. The ♀ is quite different, the yellow colour reduced to central spots in the forewing and to the basal part in the hindwing. Guiana, Amazon, Peru: the figured ♂ originates from the Rio Songo in Bolivia.

I. venata *Dgn.*, (= *veneta* *Dgn.*) (45 b). Body and forewings dull ochreous-orange, the forewing in the distal half somewhat brownish; hindwings pale yellow, antennae and legs black. The ♂ has on the forewing beneath, near the base below the cell, a small round scent-spot. Colombia.

I. hippia *Cr.* (= *albicollis* *Wkr.*, *lemba* *Drc.*) (45 d). The proximal half of the forewing is greyish, violettish-brown, the distal half pale yellow with obsolete guttiform spots. Easily recognizable by the scent-organ of the ♂ exhibiting on the forewing beneath a chalky, round felt-spot with a shiny border, and on the hindwing above a similar scent-spot occupying almost the whole costal part of the hindwing. In the ♀ the middle of the forewing is crossed by a yellow macular band bordered with red, and the hindwings are dark red. From Panama to Central Brazil; particularly in Costa Rica, on the Volcano Irazu.

I. albicoxae *Schs.* Rather similar to *hippia*, but the colours are brighter, the proximal half more distinctly marked purple, the distal half of a bright yellow. Easily discernible by the scent-spot being so much smaller than in *hippia*, that it by far does not distort the hindwing so much. Guiana.

I. melanopasta *Dgn.* (45 g). Scheme of markings similar to the preceding, but the dark part of the forewing is expanded so far towards the margin, that there remains only a yellow marginal band of 2 or 3 mm width, being above and below pointed and above the middle of the border indented. Besides the dark part of the forewing is intermixed with black dots and small streak-spots and purple interspersions. Hindwing with a dark scent-spot in the dull yellow costal half, anal half pink. Guiana, also in East Colombia.

I. lineatus *Drc.* (45 d) has entirely the shape of an *Automolis* or *Evius* and was also described as the latter. Body pale yellow, marked red, thorax with distinct black dorsal dots. Forewings dirty yellowish-grey, towards the base darker and tinged yellowish, with numerous internerval streaks; hindwings pale reddish-yellow. Panama.

I. agricus *Dyar* (45 d). This animal discovered by ROBERT MÜLLER near Misantla in Mexico initiates a series of species copying the colouring of *Automolis herois* (50 k) which likewise flies near Misantla. Through the pale-yellow forewings being centrally more strongly tinted orange, there extends a somewhat curved transverse band composed of brown longitudinal spots (above and below) or transverse spots (in the middle, round the cell-end). Base of the wing with a violetish-brown basal spot formed of thick internerval streaks. Hindwings whitish, abdomen red. Apparently rare or difficult to discover from among the number of similar *Automolis*.

I. agastus *Dyar*. Like *agricus* resembles *Automolis herois*, *agastus* is like *Automolis pichesensis* (52 a) to such an extent that it is difficult to discern. The type of marking is that of *agricus*; body white with a dark red marking. The main difference from *Automolis pichesensis* is, beside the more slender structure of the latter, that in *I. agastus* the dark streaked basal spot forms a strong contrast with the disc of the forewing, in a projecting angle, similarly as in the smaller *I. agricus* (45 d), whilst its distal margin in *A. pichesensis* runs from the base of the costa obliquely downward and outward, towards the middle of the proximal margin. Peru.

I. admirabilis *Cr.* Forewing almost exactly like in *agastus*, and like the latter very similar to *Automolis admirabilis*, *citheis* (50 k), but easily discernible from *agastus* by the crimson hindwing being only whitish at the margin. Also the abdomen is above red except the white apex. Panama to Central Brazil.

I. albidior *Rothsch.* (45 d) is to be distinguished from the preceding by the purely white distal part of the forewing, by the uniform, little curved median band, and by the basal spot being replaced by a dark

wedge extending from the base of the forewing through the cell. Hindwings white, abdomen red as far as ring 4, with white dorsal spots. Venezuela.

- daga*. **I. daga** Dgn. occurs in 2 forms; in typical *daga* from Venezuela to Peru the abdomen above is orange-yellow, whilst in **dares** Drc. (45 d) from Costa Rica it is above dark red. Across the dorsum of the abdomen a coherent row of white dots; the white forewings tinged yellowish at the margins show at the base, proximal margin and right through the middle small black transverse streaks arranged similarly as in the preceding species. This species also nearly resembles in its colouring the *Automolis*-group *critheis-pichesensis* (50 k, 52 a).
- fasciipuncta*. **I. fasciipuncta** Roths. (45 d). Entirely white, the macular transverse band of the forewing is replaced by a band of dispersed dots, and also at the base of the forewing there are only 1 or 2 fine, distinct, black dots. From the Upper Amazon through Peru and Bolivia; the figured specimen from the Rio Songo.
- ortus*. **I. ortus** Schs. Also white, the ♀ abdomen above pink. The median band similar as in the preceding, but in the ♂ showing more black streaks than dots. The ♀ also shows a small black spot before the apex (between the cell-end and distal margin), which, however, is absent in the ♂. Venezuela and South Brazil.

31. Genus: **Amaxia** Wkr.

The 14 forms composing this genus are mostly very much alike, and their type of colouring closely approximates those species of the preceding genus, that were separated from the *Idalus* as the genus *Lampruna* by SCHAU, so that we might denote the *Lampruna*-group as the transition from the typical *Idalus* to the *Amaxia*. Particularly *A. pyga* (45 e) repeats all the details of the exterior of *Idalus affinis* (45 a), whereby it also approximates the numerous copies of this form from other genera, such as *Neaxia theon* (45 k), the ♀♀ of several *Paranerita* etc. Head with a rather robust proboscis and in the ♂ doubly combed antennae, the last palpal joint stunted. Forewing with a long costal margin and short proximal margin, the border there fore very oblique, hindwing in the ♂ distorted (partly by scent-organs), and the venation therefore inconstant. Sometimes the costa is lobately indented anteriorly (*A. osmophora*), in order to cover an androconium on the forewing beneath, sometimes the shape of the forewing approximates the normal one (*A. pardalis*). Between the submedian and the median vein there is always a broad area, being so large that e. g. in *osmophora*-♂ it occupies more than half the wing. The butterflies are presumably without exception taken at the light; nothing is known of the larvae.

- pulchra*. **A. pulchra** Roths. (45 e) is the largest and most beautiful species of the genus. Before the apex of the forewing an indistinct purple-brown cloud. Hindwings pale pink, abdomen above dark red. Central Brazil and Peru.
- apyga*. **A. apyga** Hmps. (= *pyga* Drc. nec Schs.) (45 e) is almost the size of *pulchra*, but the cloud before the apex of the forewing is broken up into minute round spots, and the hindwings are dark brown, so is the dorsum of the abdomen. Costa Rica to the Amazon.
- pyga*. **A. pyga** Schs. is marked and coloured almost exactly like *apyga*, and differs merely by the ♂ hindwing beneath not exhibiting the large, distinct androconial spot, and being therefore a little differently shaped. Honduras, Rio de Janeiro.
- hebe*. **A. hebe** Schs. (45 e). Like the preceding, but the abdomen above of a bright purple-red instead of brown. Rio de Janeiro and Minas Geraes; it greatly resembles *Idalus costaricensis*, but it has a large, double, brown preapical spot surrounded by a joint purple line.
- flavipuncta*. **A. flavipuncta** Hmps. (45 e) is somewhat smaller than the preceding species; the violettish-brown spot of the base of the forewing is not so intensely coloured; nor do the small spots before the apex of the forewing come out prominently anymore. From the peak of the Tijuca near Rio de Janeiro.
- dyuna*. **A. dyuna** Schs. (45 e). Spotting of the forewings particularly abundant and the minute spots very regularly arranged. The scent-organ of the male on the hindwing beneath only small. Like the preceding from South Brazil; reported also from Peru.
- osmophora*. **A. osmophora** Hmps. (= *dyuna* Drc. nec Schs.) (45 e) greatly resembles *dyuna* Schs., but it is to be recognized by the costa of the hindwing, in order to get room for a larger scent-organ, being much more indented to a lobe; on the forewing above the dark spot above the proximal margin is more intermixed with yellow. Costa Rica, Venezuela.
- consistens*. **A. consistens** Schs. (45 e). Hindwing of the ♂ still smaller than in the preceding. The yellow distal part of the forewing is much more scantily spotted. The hindwing which is tinged rosy-red in *dyuna*, exhibits here the middle part covered with brown. — **maroniensis** Roths. is a form of it, in which the brown of the hindwing is reduced to a dot below vein 6 and to a subterminal band in the inner-marginal area, interrupted by the submedian fold. Guiana.
- pardalis*. **A. pardalis** Wkr. (45 e, f). Here also the large, violettish-brown spot near the base of the forewing begins to dissolve into an interrupted cloud owing to yellow and red embeddings; particularly above the

middle of the proximal margin and at the base of the forewing there appears bright yellow bordered with red. Hindwings above pink, in the ♂ beneath with a large scent-spot. Mexico and Amazon District.

A. parva *Rothsch.* (45 f) is recognizable by its small size, the pale spotting and the almost transparent *parva*. hindwings. Surinam and Amazon (Manaos).

A. chaon *Drc.* (53 e). Easily recognizable by brilliant silvery dots at the base of the forewing, above *chaon*. the proximal margin and below the middle of the costa. Otherwise very much like *Zatrephes Pseudopremolis* (53 b). From Costa Rica, Ecuador, Amazon and Guiana.

A. divisa *H.-Schäff.* This butterfly figured by HERRICH-SCHÄFFER without the patria being stated, *divisa*. has not been found anymore. It undoubtedly belongs here. HAMPSON presumes it to be the ♂ of a species the ♀ of which was described as *Automolis marcapota* from Peru by DRUCE in 1907. (Comp. p. 370).

A. erythrophleps *Hmps.* (45 f). This small butterfly also greatly deviates from the otherwise very *erythro-* similar *Amasia* and forms already a transition to the closely allied *Phaeomolis*. Forewings yellow, the violettish-*phleps*. brown colouring arranged to 3 transverse macular bands dying away towards the proximal margin. At and before the border 3 rows of small black dots. Guiana and Amazon District.

32. Genus: **Aphyle** *Wkr.*

A genus partly consisting of butterflies with broad and ruddle-red forewings, partly of such with narrow not red forewings. Easily discernible from the *Amasia* by the upper median vein of the forewing rising in *Aphyle* with the last radial from the upper cell-angle, while in *Amasia* it branches off far before it. The ♀♀ which are, strange to say, in this genus more frequently taken than the ♂♂, have very stout abdomens. The centre of the range of the genus is near Teffé on the Amazon, from where few species are distributed as far as Guiana, one to Costa Rica.

A. steinbachi *Rothsch.* (45 f). The smallest and southernmost species. Sooty greyish-brown, the *steinbachi*. forewings striped lighter; head and collar yellow. Bolivia.

A. margaritacea *Wkr.* (45 f). White, the costal margin of the forewing in the ♂ yellowish, hindwings *margarita-* with a rosy tint. On the forewing a small black band defines the apical part, another the basal part, and another *cea*. being interrupted in the middle extends from the middle of the costal margin to the anal angle. The figured specimen originates from Teffé (Ega). — **affinis** *Rothsch.* (45 f) has a yellow ground of the forewing; from the *affinis*. Upper Amazon and Peru.

A. cuneata *Hmps.* Forewings white, the dark streaks more irregular; base, costa and border of the *cuneata*. forewing marked darker and tinted buff. Hindwing diaphanous white, at the anal margin tinted dark red; abdomen quite vermilion. Only very little larger than the preceding. Guiana.

A. albipicta *Dgn.* (45 g). Forewing at the costal margin broad brown, which colour emanates into *albipicta*. the wing and forms yet a large, irregular, cloudy spot at the proximal angle; hindwings and abdomen dark purple pink. Guiana.

A. incarnata *Hmps.* (45 g). Body and wings above bright ruddle-red with a yellowish-hyaline distal- *incarnata*. marginal spot projecting towards the cell-end in an obtuse tooth towards the base. Through the forewing extend 2 delicate, dark transverse lines. From the Amazon; the figured specimen from Teffé. — In the very similar **incisa** *Rothsch.* (45 g) from Fonte Boa the yellow marginal band in the apical part of the forewing is *incisa*. very narrow. — **intorta** *Schs.* (45 g) from Costa Rica is much larger, and the dark transverse lines of the forewing *intorta*. are extinct.

A. conifera *Dgn.* (45 g) is still larger than the preceding; quite ruddle-red, except a laciniiform, faintly *conifera*. yellowish hyaline spot on the lower marginal half, above the proximal angle. Beneath the hindwings are almost white. Before me only from Medina (East Colombia, at an altitude of 500 m), from the Coll. FASSL.

33. Genus: **Neonerita** *Hmps.*

This genus is composed of 7 or 8 medium-small Arctiids, in the colouring and also in the structure almost exactly like the preceding, except the lower radial of the forewing having a footstalk of about 2 or 3 mm length in common with the upper median vein. This footstalk is effected by the discocellular extending not transversely, but quite obliquely from in front and outside towards behind and inside. The genus based upon this chance occurrence might be the more artificial as the antennae of the ♂♂ are in some species plain, in others rather long doubly combed; the abdomen is sometimes long and slender, sometimes it projects a little beyond the anal angle; the hindwings are sometimes round, small and of the usual shape, sometimes changed in their shape and venation by complicated scent-organs covering the whole surface of the wings. The larvae not yet being known of a single species, are probably partly brushy partly tuft-haired bear-caterpillars.

- minerva*. **N. minerva** Schs. (45 h). From South Brazil (Novo Friburgo). Almost exactly coloured like the preceding, but the yellow hyaline spot of the forewing extends broadly from the distal margin almost to the costa, where it only leaves a thin red stripe.
- dorsipuncta*. **N. dorsipuncta** Hmps. (45 h) entirely resembles *minerva*, but it is somewhat smaller, the hyaline yellow band-like spot of the forewing is narrower by two thirds, more oblique and somewhat irregularly defined. In the discal part of the ground-colour of the forewing there are orange yellow spots embedded, encircled by hemochrome. Hindwings and abdomen purple-red, the latter with a white dorsal dot. Described from South Brazil; the figured ♂ from Villavicencio in Colombia, taken by FASSL; several specimens before me also from Mexico.
- perversa*. **N. perversa** Rothsch. (45 h) is much smaller than all the other species of the genus; the hyaline band of the forewing still narrower, less curved, its proximal edge irregular. The ♂ hindwing beneath covered with dense hair. Guiana and Amazon District.
- arcifera*. **N. arcifera** Dgn. (45 h). The yellow hyaline part does not only form a band on the forewing, but it occupies the whole distal part and only leaves a brown costal spot before the apex, thus producing a colouring exhibited also by many neotropical Arctiids, such as *Amavia pulchra* (45 c), *Idalus affinis* (45 a) etc. Colombia, discovered by FASSL on the Quindiu Pass.
- haemasticta*. **N. haemasticta** Dgn. is almost exactly like *arcifera*, but the yellow hyaline part is inside irregularly defined and set with scarlet dots. Peru, Colombia; in Colombian specimens the proximal part of the wing and the costal spot before the apex are often paler.
- syrrissa*. **N. syrrissa** Drc. (45 h) likewise greatly resembles *arcifera*, but the spot before the apex is reduced to small brown crescents. Peru.
- yahuasae*. **N. yahuasae** Joicey. Very much smaller than *syrrissa*, scarcely half its expanse; the proximal, pale purple-red part of the forewing extends from the middle of the costa beyond the anal angle; on its somewhat curved distal border some small black scales; before the apex a large, round, pale purple-brown spot bordered with dark. Hindwings pale yellow, in some places tinted pink. Peru.
- metaphoenicea*. **N. metaphoenicea** Joicey. Still smaller than the preceding which it resembles, but the round, subapical spot of the forewing is proximally dark and at the margin lighter. The hindwings are pale purple-pink, the basal and costal-marginal areas whitish. From French Guiana; discovered by LE MOULT.

34. Genus: **Evius** Wkr.

This genus consisting so far only of 3 species is allied to the preceding, but the upper median vein of the forewing rises separately from the lower cell-wall, a good distance before the lower cell-angle. In the system of the subcostal the species comprised here correspond, but they show sometimes longer sometimes shorter antennal combs, and sometimes the ♂ hindwing is distorted by scent-organs.

- aurococcinea*. **E. aurococcinea** Wkr. approximates the forms of the *arcifera*-group (45 h) from the preceding genus, but it differs by the yellow distal part of the forewing occupying only about a third of the wing and bordering on the purple-brown proximal part in an entirely uniform semi-circle, beginning exactly in the apex, extending below the costa, passing by close at the transverse vein and terminating exactly in the anal angle. Through the basal part of the costa there extends a white ray; beneath the costal margin is streaked dark. Body and hindwings purple-red, the body in some places tinted brown, the hindwing towards the margins paler. The type (from Pará), which is not before me, has an expanse of 38 mm.
- cochenouri*. **E. cochenouri** Schs. Size and marking of the forewing somewhat similar to that of *Aphyle incarnata incisa* (45 g), but the forewings at the costal margin are more brown, the terminal yellow area more than twice as broad as in *incisa*, and its proximal edge projects proximally behind the cell in a sinus. Between the radial veins 2 brownish dots. Hindwings pale yellow, in the inner-marginal part tinted pink. From Costa Rica. — The colouring of this species is so exactly reproduced in the Arctiid *Premolis flavithorax* Rothsch. (50 b), that we can refer to its figure. The *Premolis*-♂, however, has a different venation, particularly in the hindwing, on the under surface of which it shows a large, subcostal, oval stigma being absent in *Evius*.
- albascripta*. **E. albascripta** Schs. (53 f) is presumably scarcely congeneric with the preceding, the ♂ with greatly distorted veins. Expanse hardly more than 30 mm; recognizable by 2 long hair-locks hanging in the ♂ down at the sides of the abdomen. The latter itself very long, projecting far beyond the anal angle. In the disc of the forewing there is on the brown forewing marked somewhat purple a large, diaphanous yellow spot being indented below the costal margin; below and before the latter, as well as in the apex white, short streaks partly bordered with purple. ♂ hindwing in the anal part extended like a lobe, purple-red, the inner-marginal fold white. French Guiana.

35. Genus: **Araeomolis** *Hmps.*

This genus consisting of 6 forms likewise contains both normally shaped butterflies and such with long lobated hindwings. Colours throughout yellow and red, the latter colouring being often preponderant. ♂ antennae doubly combed; tibial spurs short, abdominal base above roughly haired. In the forewing the upper median vein rises close before the lower cell-angle; the 4 subcostal veins are arranged in such a way that the lowest rises yet before the middle between the cell-end and apex. Cell somewhat more than half the length of the costa; discocellular proximally angled. No areola. The genus is scarcely to be called normal: the diagnose of the genus: „forewings long and narrow“ is not correct with regard to the ♂♂ of some species (e. g. *A. sanguinea* *Hmps.*). Of almost all the species but one or few specimens are known; they consequently seem to be very rare and are confined to the northern parts of South America.

A. persimilis *Rothsch.* (45 i). Forewings violettish-red and spotted pale yellow, in the pale yellow *persimilis*. ring-spots small red dots, behind the cell-end a small white vitreous spot. Hindwings quite pale pink. Head and thorax pale yellow with a red line, abdomen crimson pink. A rather small butterfly; presumably the most widely distributed species. From Surinam to the Amazon and Peru.

A. rhodographa *Hmps.* Size and shape of the preceding, but the small white vitreous spot behind *rhodographa*. the cell-end smaller, the basal part of the forewing more finely marked, containing red, partly strongly curved lines in the light yellow spaces between the veins. Hindwings yellow, tinged pink in the apex.

A. guianensis *Joicey* from French Guiana is almost $\frac{1}{3}$ larger than *rhodographa*, the forewings pale *guianensis*. greyish-brown, speckled bone-white and with red vein-streaks; in the submedian space purple embeddings; in and below the cell white spots proximally bordered with red, at the border white internerval spots, in front of them black streaks; hindwings pale purple pink, the costal-marginal area as far as beyond the middle whitish. Head and thorax white, marked purple, abdomen purple. Only 1 ♀ known, discovered by LE MOULT on the Maroni River.

A. sanguinea *Hmps.* (45 i). Immediately recognizable by the shape of the ♂ hindwing being lobatedly *sanguinea*. extended in the apex and anal part, and between deeply indented. Somewhat larger than *persimilis*. Forewings of a bright dark red with yellow veins in the distal part and small yellow rings and streaks in the proximal part, the hindwing purple with a yellowish brown inner-marginal area. St. Jean Maroni in French Guiana. The species recalls *Eriostepta bacchans* (45 i), the border of the hindwing of which, however, is in the ♂ not indented below the apex.

A. nigripuncta *Joicey* (45 l), from the same district, is the size of the preceding and has also scarlet *nigripuncta*. forewings marked yellow, with a white costal margin streaked red-brown, in and below the cell black dots, in and behind the cell-end bands of brown punctiform spots, being united downwards, an antemarginal row of small brownish spots. Hindwings light purple-pink, behind the cell hyaline.

A. haematoneura *Joicey* from Colombia. ♂ somewhat smaller than *nigripuncta*, head and thorax *haematoneura*. like in most of the *Araeomolis* yellow, marked purple, and the abdomen red. Forewings greyish-brown with white-yellow spots and red markings, the spots mostly bordered with red and some pupilled white; hindwings pale pink with a whitish costal area. ♀ unknown.

36. Genus: **Neaxia** *Hmps.*

This genus also contains about half a dozen of species known, the ♂♂ of which mostly exhibit very much altered, stunted hindwings. Beneath the typical species — *theon* — shows a furry scent-spot round the upper cell-angle of the hindwing, and also the forewing has an oval stigma above the submedian, before its centre. Moreover, the very small hindwing of the ♂ is at the costa very far bulged out, in the apex, however, indented and below it curtailed. The genus is very natural and the species are very much alike; the butterflies are apparently rare; the ♀♀ are mostly unknown.

N. klagesi *Rothsch.* (45 k). Yellow, the forewings rather scantily spotted violettish-red, hindwings *klagesi*. tinged quite pale rosy-red, at the border broadly shaded with brown. Surinam.

N. ockendeni *Rothsch.* (45 k). The forewings quite similar, but broader, the hindwing of the ♂ without *ockendeni*. the brownish-grey marginal shade. Upper Amazon (Fonte Boa) and Peru.

N. theon *Drc.* (45 k). This typical species shows the dark spots of the forewing in the proximal half *theon*. of the wing flown together to a purple brown cloud being only at the base interrupted by yellow and marked violettish-red and grey. The hindwing is white, towards the margin darker; the scent-spot denoted by HAMPSON to be orange, is likewise white in the figured specimen from Merida. Venezuela and the adjoining Colombia (Villavicencio).

egaënsis. **N. egaënsis** *sp. nov.* (45 k). Forewings very much like in *theon*, but the hindwing considerably smaller, at the proximal margin rosy, in the anal part tinged dark grey. The scent-spot of the hindwing beneath more than twice as large, pink in a yellow ground, the abdomen above purple-pink, not greyish-brown as in *theon*. Teffé on the Amazon; type (♂) in the Museum Senckenberg at Frankfurt on the Main (Coll. SEITZ).

bella. **N. bella** *Schs.* (45 k). Spots of the forewings very intensely coloured, but smaller than in *egaënsis* and not so close together; an antemarginal row of dots, in the place of the sagittiform spots of *egaënsis*. Hindwing of a bright purple pink, the whole distal half blackish. French Guiana.

kennedyi. **N. kennedyi** *Rothsch.* (45 k) is larger than *bella* with a rounder border of the forewing; the spots of the forewing in the distal part pale and blurred, in the inner-marginal area flown together, the base of the forewing yellow. Hindwings much larger and more regularly shaped, yellow with a rosy basal part. Minas Geraes.

flavicollis. **N. flavicollis** *Rothsch.* (45 k). Forewing in the yellow apical half intermixed with but few pale reddish dots, only before the apex a small, costal, violettish-red cloud; on the whole proximal margin there rests a violettish-red nebulous spot being convex above with darker margins. Hindwings pink; head and collar yellow, thorax violettish-brown, abdomen dark red. The distribution of colours on the forewing is already more like that of *Neonerita arcifera*, *syriassa* (45 h) etc., whilst the other *Neaxia* resemble *Amoxia pardalis*, *osmophora* (45 c, f) etc. Fonte Boa (Amazon).

gnosia. **N. gnosia** *Schs.* entirely resembles the preceding, but in the yellow part of the forewing, between the radial veins, some large, purple-brown spots are embedded. British Guiana.

37. Genus: **Eriostepta** *Hmps.*

Like the preceding genera this also contains about half a dozen forms; they deviate, however, more from each other, than the *Neaxia* do. Even the fleecy-like hairing of the surface of the hindwing, mentioned in the diagnose of the genus, does not apply to all the species having been inserted here later on. Also here the hindwing of the ♂ is often distorted by scent-organs; sometimes the proximal margin, sometimes the area of the median is monstrously prolonged. The forewing, as a rule, is broader than in most of the *Neaxia*, but similarly coloured and marked. Palpi and proboscis, like there, strongly developed, the palpi with a long middle joint and very short terminal joint. The 1st subcostal vein rises far before the upper cell-angle; the cell itself is longer; the uppermost median vein rises almost at the cell-corner, close at the lower radial. Hindwing beneath with a large, subcostal androconial pad. All the species have become known only after 1900, and we know nothing about their early stages nor their habits.

bacchans. **E. bacchans** *Schs.* (45 i). Forewings scarlet with yellow veins and yellow streaks, small, blackish guttiform spots in, behind and below the cell and in an angled chain extending from the costa before the apex to the middle of the proximal margin. Hindwing purple with a yellow border. French Guiana.

fulvescens. **E. fulvescens** *Rothsch.* (45 i). Forewings yellow, with a fine, vanishing red vein- and streak-marking. At and before the margin, and dispersed in the costal half, there are numerous, small brown dots; the hindwings coloured almost like the forewings, somewhat paler, without any distinct marking. Guiana to the Amazon.

roseireta. **E. roseireta** *Hmps.* from the Amazon is almost like the preceding, and also shows distinctly the hairing of the hindwings, but the red striation of the forewings is more distinct, in the anal angle more intense macular marking.

peruana. **E. peruana** *Rothsch.* (45 k) entirely resembles again *Neaxia* by its shape, colouring and marking: in the yellow area there are beside smaller violettish-brown dots 4 larger oval spots before the apical area. Peru.

beata. **E. beata** *Dgn.* is almost exactly like *peruana* (45 k), but the subapical spots of the forewing are flown together to an irregular cloud. Guiana and Peru.

pseudamaxia. **E. pseudamaxia** *Rothsch.* likewise shows the colouring of *peruana* (45 k), but it is smaller and in the apical area of the forewing there is, instead of a transverse cloud formed by the 4 oval spots below each other having flown together, a spot being slit up at all its edges, and the hindwings being without markings in *peruana* exhibit here the border shaded dark and in its middle a violettish-brown cubiform spot. Guiana.

38. Genus: **Paranerita** *Hmps.*

This genus bears a relationship to the following genera (*Neritos*, *Hyponerita*) similar to that between the *Prumala*, *Neaxia*, *Idalus* etc., i. e. certain colorial types are repeated again and again. In the catalogues which have exclusively laid great stress upon the neuration (in this instance upon the presence or absence of an anastomosis of the subcostal system) *Neritos* (without an areola) is, therefore, separated far from *Paranerita*.

and *Hyponerita* (with an areola). HAMPSON, however, already in the supplement to his well-known Catalogue, has eliminated this rigour by bringing the undoubtedly allied genera together, and we may be in doubt whether these genera are not merely subgenera. We see here nothing else but the repetition of parallels of forms, as we have recognized in the groups of day-butterflies *Hypoleria*, *Pseudoscada*, *Pteronymia*, *Leucothyris* and still more conspicuously in *Melinæa*, *Mechanitis* and *Ceratinia* in Vol. V of the *Macrolepidoptera* (t. 31 to 40). The larvae of the genera *Neritos*, *Para-* and *Hyponerita* presumably also resemble in being densely covered with variegated brushes and at the anterior and posterior parts with long pencils. These larvae being sometimes quite curiously disfigured by their hairiness bring the group of these genera decidedly nearer to the *Syntomidæ*, the strict separation of which from the *Arctiids* we have already several times denoted to be very difficult, if tenable at all. With respect to this we may mention that we have seen also in the *Syntomidæ* certain types being again and again repeated in the most various genera, so that often only by means of examining the neurulation it could be decided, whereto the specimens belonged, exactly like in the *Ithomiinæ*, too. But also in the *Syntomidæ* it has proved, particularly by recent breeding experiments, that the venation is by no means decisive in all cases, and we may, therefore, expect that the examination of the veins also sometimes misleads us in the *Arctiids* of the *Neritos*-group; the more so since the differences of venation are frequently founded upon male specimens having in very many cases strongly developed secondary sexual marks, whereby the wings may sometimes be entirely disfigured and the venation disarranged. The separation of the following genera must, therefore, for the present be regarded more as a means for a generalization of the very multiform groups than for the expression of natural directions of the development. — The genus contains almost 40 forms known, all of which — except one — have been discovered during the two last decades. Except some few, somewhat deviating species, all the types are very much alike. Mostly a boundary-line extending obliquely from the costa towards the anal angle separates a purple-brown proximal part from a yellow apical half of the wing, which again surrounds an apical disc of a dark colour. Nearly all the species of the genus seem to be rare; they rest in day-time hidden on the under surface of leaves and come to the light in the evening. Of the genus *Paranerita*, the life-history of no species is known as yet, but the larvae are presumably similar to those of *Neritos*. From the latter the *Paranerita* are distinguished by the anastomosis between the 2nd subcostal vein with the footstalk of the 3rd to 5th, from *Hyponerita* by the areola being formed by the connection of the 2nd subcostal vein with the third. Type: *P. polyxenus*.

P. maculata Rothsch. (45 l) is one of the smallest forms. Forewings greyish red-brown with 3 rows *maculata*. of silvery white guttiform spots forming angled chains near the base and before the middle, standing alternately, however, in the marginal area. Hindwings yellowish-pink with a blackish marginal band. From Fonte-Boa (Amazon).

P. fenestrata Rothsch. (45 l). Likewise from the Amazon; it somewhat recalls *Neonerita dorsipuncta fenestrata*. (45 h); but the hyaline window in the disc of the forewing is narrower and does not reach the border; the hindwings quite light whitish-grey, also the abdomen yellowish-grey, not red. At the middle of the border of the forewing some minute light spots.

P. rosacea Rothsch. (45 l) is only as large as *maculata*; forewings, costal part of the hindwings, head *rosacea*. and thorax pale yellowish-brown; abdomen and hindwing carmine-pink. Venezuela and Amazon District.

P. haemabasis Dgn. (45 l). Blackish-brown, head, thorax, bases of the wings and of abdomen light *haemabasis*. red. Forewings with a dull, violettish-blue reflection. The posterior legs of the ♂ are transformed into stout paws by woolly hair; the scent-organ on the forewing beneath is an extensible, thick, white pencil. From Muzo in Colombia; discovered by FASSL.

P. alboapicalis Rothsch. (45 l). Head, thorax, and forewings except a white apical spot blackish-brown, *alboapicalis*. hindwings, except the black border, light pink, and the abdomen red, except the black apex. Surinam.

P. polyxenoides Rothsch. (45 l). Hindwings like in the preceding, but the blackish-brown forewing *polyxenoide*. has a yellow apical spot, a small yellow triangle in the middle of the costa and a still smaller one in the middle of the margin. Vertex yellow, the whole abdomen red. Guiana, Amazon and Peru.

P. polyxenus Drc. (45 l) is quite similar, but the yellow triangle at the costa larger, that at the border *polyxenus*. smaller than in the preceding. Hindwings almost quite black, except the yellow basal part. Bolivia.

P. grandis Rothsch. (46 a) is twice as large as the preceding with broad wings; hindwings large, so *grandis*. that the abdomen scarcely projects beyond the anal angle. Costal spot much larger than in *polyxenus*, at the border a series of small yellow spots, that in the middle of the margin being the largest. Hindwings light honey-coloured, head yellow, abdomen red. Colombia to Peru; the figured specimen from Medina in East Colombia.

P. niobe Schs. (46 a) from Costa Rica is somewhat smaller and quite similarly marked and coloured, *niobe*. but the apical spot of the forewing is connected with the small spots in the middle of the margin by yellow, and the hindwings are not yellow, but rosy-red.

- bione*. **P. bione** Jones (45 k) is coloured like the preceding, but the yellow costal spot extends proximally along the costa to the base, and the spot in the middle of the border extends farther into the wing. Santos (São Paulo, Brazil).
- irregularis*. **P. irregularis** Rothsch. (46 a) is about only half as large as *bione*; the yellow costal spot of the forewing, being quite flatly triangular there, is here very large and high, so that it reaches as far as the submedian area. From the direction of the proximal margin it is approached by another yellow spot bordered with red, and the marginal yellow is well developed. Surinam.
- complicata*. **P. complicata** Schs. (= *plagosa* Rothsch.) (46 b) is larger than *irregularis*, but smaller than *bione*. The whole distal margin is occupied by 3 large yellow spots pupilled red; the yellow costal triangle is also bordered by a bright scarlet. Hindwings pink. Guiana.
- patara*. **P. patara** Drc. (46 b). Larger, the structure of the body much stronger. The forewing has a very large, lemon-coloured costal spot, a large apical spot and a third spot extending from the middle of the border to the anal angle. Hindwings pink with a dark border. Guiana.
- suffusa*. **P. suffusa** Rothsch. (46 b) shows on a purple-brown forewing marked red, in the middle of the costa, a large, dark yellow, saeciform spot and an irregularly defined, yellow marginal spot. The yellow colour of both is surrounded by hemochrome, besides the forewing is marked red; thorax brown, marked red; hindwings and abdomen of a beautiful purple-pink. British Guiana. — In the form **trinitatis** Rothsch. from Trinidad the red markings on the forewing are more strongly developed, particularly in the apex, and the yellow, saeciform costal spot of the forewing is narrower.
- peruviana*. **P. peruviana** Rothsch. (46 a) is quite similarly coloured and marked as *patara*, but the yellow spots on the forewing are somewhat smaller and of a deeper yellow, the hindwing without the dark border, unicolorously dark pink, the abdomen brown with a yellow apex. Peru.
- flexuosa*. **P. flexuosa** Schs. (46 a). The costal spot is here more trapeziform, the yellow apical spot is broadly connected with that above the anal angle, the hindwings are sooty dark below the cell, and the abdomen is dark purple-red. Costa Rica. Discovered by SCHAUS.
- amelia*. **P. amelia** Schs. (46 a). The yellow extends here as a regular marginal band along the distal margin, the costa and base of the proximal margin being likewise yellow, bordered with red: the yellow spot on the middle of the costa is irregularly shaped. Closely allied to *flexuosa* and perhaps only a form of it. Likewise discovered by W. SCHAUS in Costa Rica.
- rubrosignata*. **P. rubrosignata** Rothsch. (46 b) is one of the smallest species. The yellow extends from the base in a broad band along the costa and occupies the whole apical half of the forewing; in the disc it encloses red markings. Chocolate-brown are only the thorax and a broad triangle situate on the whole proximal margin. French Guiana.
- peninsulata*. **P. peninsulata** Dgn. (46 a). At the costa a large, yellow trapezoid, the apex and a marginal band distending above the anal angle being likewise yellow. Somewhat larger than the preceding. Venezuela.
- aurantiipennis*. **P. aurantiipennis** Rothsch. (46 b) is one of the largest species of the genus. The violettish-brown areas the inner-marginal area and a discous spot before the apex, are inside intermixed with yellow and marked red. The discous spot is connected with the inner-marginal brown by a narrow footstalk. Body yellow, in some places tinted rosy. Guiana, Amazon.
- metapyria*. **P. metapyria** Dogn. (46 a) is coloured similarly to the preceding, but the discous spot at the apex is isolated, separated afar from the border of the inner-marginal area. Beneath the dark areas of the forewing are deep brown. Guiana, Bolivia; the figured specimen from the Rio Songo.
- metapyrioides*. **P. metapyrioides** Rothsch. (46 b). Forewings more pointed, hindwings far extended, with a long proximal margin. Next to *grandis* the largest species of the genus. Similarly marked as the preceding, but the yellow brighter and the violettish brown areas inside still lighter. Discovered by A. H. FASSL on Mount Tolima (Colombia).
- hampsoni*. **P. hampsoni** Rothsch. (46 b). One of the smallest though most beautiful species. On the forewing the violettish-brown apical area is proximally straightly cut off, before the apex itself it contains bluish-white embeddings. From the brown colour of the inner-marginal area it is separated by a large, apple-green median area. The inner-marginal area is distally secluded by a white band bordered with a dark tinge. Hindwings pink. Amazon and Bolivia; the figured specimen from the Rio Songo.
- metaxantha*. **P. metaxantha** Dgn. Instead of the green discal area the apical brown is separated by a broad, hyaline band; the hindwing is not pink but yellow. Somewhat larger than *hampsoni*; the inner-marginal area on the hindwing beneath being long-haired like a fleece in the latter species, is smoothly scaled in *metaxantha*. Colombia.

P. translucida Rothsch. (46 b) from Peru has the hyaline band of the forewing almost just as broad *translucida*, as *metaxantha*, but it is steeper, so that it terminates directly above the anal angle, not in the middle of the border. Hindwing greyish-brown with a light border, abdomen bright red. Smaller than *metaxantha*.

P. carminata Schs. (46 b). The yellow oblique band separating the purple apical part from the purple *carminata*, proximal area of the forewing, runs quite straight from the middle of the costa to the anal angle. Thorax purple, marked yellow. Abdomen red. French Guiana.

P. lophosticta Schs. (46 c). The yellow oblique band of the forewing is widened on both its ends, before *lophosticta*, the border, however, strangled; thereby the purple apical spot has already the round discous shape. Below the median, near the base a small white spot, where we notice a white hair-lock on the under surface of the wing. Hindwings pink; head with a yellow vertex, body red, above the base of the abdomen a white transverse spot. Hindwings at the apex in the ♂ deeply notched. Costa Rica, on the volcano Irazu near Orosi etc.

P. persimilis Rothsch. (46 b). The yellow oblique band more uniform, not so much strangled before *persimilis*, the border; the apical discous spot smaller, abdomen without the small white transverse band at the base. Surinam and Peru. In the ♀ the discous spot may be confluent with the purple inner-marginal area.

P. perversa Rothsch. (46 c) exceedingly resembles *lophosticta*, but it is much smaller, the apical disc *perversa*, smaller, almost exactly circular, forewing without the small white spot below the middle of the cell. Fonte Boa on the Amazon.

P. phaeocrota Dgn. (46 c). Thorax and forewing much darker brown; on the forewing the apical disc *phaeocrota*, is small and separated afar from the innermarginal brown. Hindwing pink, darkened at the proximal margin. Abdomen red. Discovered by LE MOULT on the Maroni River in Guiana.

P. androconiata Rothsch. (46 c). Very small; it rather exactly resembles *granatina* (46 c), but it is *androconiata*, considerably smaller, the hindwing of a paler light pink, and below the middle of the cell a white androconial spot. Peru.

P. orbifer Hmps. (46 d) resembles the two preceding, but it is larger than *androconiata*, the brown *orbifer*, basal area towards the yellow apical part of the forewing smoothly cut off, the apical disc darker brown; hindwing pink with a broad, black border. Abdomen pink. Colombia.

P. granatina Rothsch. (= *postrosea* Rothsch.) (46 c). Similar to the preceding, but the dark inner- *granatina*, marginal area defined in a distally convex bow towards the yellow band, hindwings and abdomen purple. Guiana, Venezuela and Bolivia.

P. sithnides Drc. (46 c). Forewings very similar to *granatina*, but at once discernible by the unicolorously *sithnides*, dirty grey hindwings. Brazil and Peru. — **P. lavendulae** Rothsch. (46 c) is a somewhat smaller form, the apical *lavendulae*, discous spot much smaller and more smoothly defined, the hindwing has a whitish-yellow costal area with a pink tinge. Guiana, Amazon, Peru. — In **P. meridionalis** Rothsch. from South Brazil the hindwing is whitish *meridionalis*, also at the base.

P. occidentalis Rothsch. (= *rosacea* Rothsch. p. p.) (46 c). A rather small species; the apical discous *occidentalis*, spot is removed more inward from the apex of the forewing, so that the apex remains rather broadly yellow; the disc itself is surrounded by purple. The basal brown spot is cut off before the anal angle, so that the anal angle itself remains yellow. Body purple; hindwing of the ♂ dark wooden-brown as in *sithnides*, in the ♀ pink. Amazon and Ecuador.

P. triangularis Rothsch. (46 c) is much larger than the preceding, more slender, the hindwing with *triangularis*, a straighter border. The dark parts of the forewing of a purer purple, the apical spot larger, irregularly defined and not surrounded by purple. Hindwings yellowish-brown. At the base of the abdomen a white transverse spot parted in the middle. Guiana and Peru.

P. inequalis Rothsch. (46 d). Size between the two preceding, the shape, colour and marking almost *inequalis*, exactly as in the following species, *Neritos macrosticta*, distinguished by exhibiting an areola in the forewing, and by the absence of the ♂ mark on the upper surface: the hindwings are also somewhat differently shaped. From Guiana through Brazil to Bolivia and Peru.

39. Genus: **Neritos** Wkr.

The genus *Neritos* likewise contains 40 forms which have only lately become known except three. These butterflies are also nearly only taken by the lantern, and on using more intensely illuminating devices their number will also increase considerably. We find here parallels to most of the colorial types of the *Paranerita*:

thus *macrostidza* mentioned above resembles *P. inequalis* (46 d) except the small fine silvery band at the base of the abdomen; *pandera* resembles *P. metaxantha* or *hampsoni* (46 b), *cotes* is like *P. niobe* (46 a), *kennedyi* like *P. peruviana* (46 a). In a similar way the colorial designs exhibit transitions to the next genus, and we find e. g. in *drucei* the image of *Hyponerita tipolis* (46 h), in *cotes* a parallel to *Hypon. ockendeni* (46 h) etc. The *Neritos* are without the areola in the forewing; the 1st and 2nd subcostal veins rise with a common pedicle rather far before the upper cell-angle; the 3rd to 5th subcostal veins are mostly petioled, too. Only of 1 species (*N. onytes*) the larva is known; a peculiar animal strongly recalling the *Syntomid* group, the 8 middle segments exhibiting strange, above truncate brushes directed to all sides, similar to the dorsal brushes of the *Dasychira*. The anterior and posterior parts exhibit 6 to 8 long white hair-pencils each. The obtuse, light brown pupa is embedded in an oviform web intermixed with hair, likewise similar as in the *Syntomidae*. Most of the species are just as rare as the *Paranerita*, only the two first are more common.

- macrostidza*. **N. macrostidza** *Hmps.* (= *onytes* *Hmps.* p. p. ncc *Cr.*) (46 d) is a small species; the purple disc in the apex broadly touches the costa and extends very precisely in front of the distal margin, leaving a very fine yellow margin. Margins of the yellow oblique band only very feebly dentate; abdomen hemochrome, with a conspicuous white transverse spot at the base. Hindwings pink, at the apex parted into 2 tips by a deep indentation. Guiana to Brazil and Bolivia; the most common species of the genus.
- onytes*. **N. onytes** *Cr.* (♂ = *psamas* *Cr.*) is quite similar, larger, without the distinct white abdominal spot, the ♂ hindwing indented at the apex, but not sharply serrated, the hindwing itself in both sexes above greyish-brown. In the ♀ — according to HAMPSON, however, also sometimes in the ♂ — the dark apical disc flows in the middle of the forewing together with the brown of the basal half, so that it resembles *N. cotes* (46 f) which, however, has honey-coloured hindwings. Widely distributed, from Panama through Colombia and the Amazon District as far as Bolivia and Peru. — To this butterfly presumably belongs a yellowish-green larva showing across the dorsum and on the sides rows of pink, truncate brushes with purple crowns. Anterior and posterior parts light yellow, with 6 to 8 long white pencils each; head brown. It lives on the lemon-tree, changes into a red-brown pupa in an oviform cocoon intermixed with hair, yielding the imago already after 7 days. — Not rare.
- neretina*. **N. neretina** *Dyar* (46 d). Recognizable by the purple-brown apical disc of the forewing thinning the yellow oblique band in the middle of the wing by growing towards the basal brown; hindwings almost purely white. Venezuela, Peru.
- metaleuca*. **N. metaleuca** *Dgn.* (46 d). On the contrary, here the yellow oblique belt of the forewing is particularly broad, and the proximal margin of the apical disc somewhat indented. Hindwings whitish. Venezuela.
- albicollis*. **N. albicollis** *Hmps.* (46 d). Band of the forewing still broader than in *metaleuca*; apical disc and base brown in the forewing with intermixed, bluish-violet, lighter parts. Hindwings pink. Recognizable by the white collar. British Guiana.
- cyclopera*. **N. cyclopera** *Hmps.* (46 d). The yellow belt of the forewing extends here particularly flatly, the apical disc being very ellipsoidal. Hindwings orange-yellow, broadly bordered with a dark brown. French Guiana.
- purpurascens*. **N. purpurascens** *Rothsch.* (46 d). One of the smallest species of the genus. The apical disc circular, somewhat removed from the distal margin which remains broadly yellow. The hindwings comparatively large, circular, hardly noticeably retracted at the apex, yellow, with a faint pink hue. Fonte Boa (Amazon).
- phaeoplaga*. **N. phaeoplaga** *Hmps.* (46 e). Size and colouring of the preceding, discernible by the much smaller apical disc leaving the apex, costal margin and border broadly yellow; the distal margin of the brown basal area is dentate; hindwings small, below the apex very much retracted, purple pink with a dark brown spot at the middle of the border. French Guiana.
- odorata*. **N. odorata** *Rothsch.* (46 e). Also in this species the apical disc is small and is distant from the border which remains yellow; but the wings are much broader, the hindwings almost circular, below the apex somewhat retracted, yellow, with a faint rosy hue; the head yellow. Fonte Boa (Amazon).
- samos*. **N. samos** *Drc.* (46 e). Recognizable by the straightly cut-off distal margin of the brown inner area; the yellow oblique belt of the forewing rather broad; hindwings with a faint rosy hue. Honduras.
- sanguipuncta*. **N. sanguipuncta** *Schs.* In contrast with the preceding, the distal border of the basal brown is here undulate and also the periphery of the apical disc is not smooth, but irregular. Venezuela.
- drucei*. **N. drucei** *Rothsch.* (46 e). Distinguished by the quite uniform, somewhat hyaline oblique band, the margins of which are quite smooth. Hindwings dull pink, in the anal part somewhat extended. Guiana. — **fassli** *form. nov.* is quite similar, but the hyaline yellow band at the costa almost twice as broad. From Villaviecio in East Colombia; type in the Coll. FASSL.

N. repanda Wkr. (= *earnea* Weym., *diversa* Rothsch.) (46 d) is likewise very similar to *drucei repanda* (46 e), but it differs by the apical disc of the forewing not being smoothly margined and somewhat removed from the border; the ♂ hindwing below the apex very much retracted, light yellow, with a rosy hue. In the ♀ the apical spot flows together with the basal dark brown, as in many others of the genus, whilst in *drucei* and *fassli* it remains far apart. South Brazil: Rio, Santos.

N. pandera Schs. (= *ampla* Dogn.) (46 e), from Guiana and Venezuela, has the oblique band of the *pandera* forewing still much broader than all the others and almost quite hyaline; the brown inner area lighter at the base and proximal margin; hindwings yellow.

N. purpureotincta Joicey (46 e). As large as *abdominalis* (46 g). The basal chocolate-brown extends *purpureo-* here to the middle of the costa and to the border above the anal angle, towards the pearl-white apical part *tincta*. finely bordered with red, the apical part towards the apex faintly tinted ochreous; the apical disc rather large, elliptic, purple grey, finely encircled with red, extending down to the lower radial. Hindwings whitish, tinted dull pink, particularly in the inner area. Beneath the hindwing has a purple-pink costa. French Guiana, based upon 1 ♂ captured by LE MOULT.

N. gaudialis Schs. (46 c). Instead of the apical disc, a broad, dark violettish-brown distal band extends *gaudialis* from the costa towards the proximal angle of the forewing, where it is fused with the basal brown, leaving a large costal triangle and the border yellow. French Guiana.

N. carmen Schs. (46 e) entirely resembles *gaudialis*, but before the middle another yellow band *carmen* crosses the forewing. Hindwings blackish-brown, at the costa and proximal margin lighter. French Guiana.

N. coccinea Schs. Entirely like the preceding, distinguished only by the subbasal yellow band *coccinea*, being divided into 3 spots, and the abdomen not being brown but yellow with a rosy tint. Likewise French Guiana.

N. kennedyi Rothsch. (46 f). Smaller and with more pointed wings than the preceding; not the whole *kennedyi* margin of the forewing is yellow, but there remain only yellow marginal spots at the apex and between the median veins. Hindwings not dark brown, but quite light pink. Minas Geraes. Brazil.

N. cotes Drc. (46 f). Almost exactly like *gaudialis* (46 e), but the yellow border projects triangularly *cotes* towards the disc, above the proximal angle. Thereby similar to the total exterior of *onytes*. Central America.

N. flavorosea Wkr. In the ♂ the forewing has a violettish-red oblique shade from the middle of the *flavorosea* costa to the middle of the border; otherwise the colour of the forewings is purple violet. Hindwings orange-yellow. The ♀ has an orange-yellow triangular spot at the middle of the costa and of the border. Mexico and Honduras.

N. flavimargo Joicey from the Rio Ueayali in the Amazon District resembles the following species, *flavimargo*, but it is a little smaller. The costal yellow triangle extends into the purple-brown forewing as far as the transverse vein; it is continued at the costa, bends round at the border which it leaves very narrowly yellow, this colour projecting in the middle of the border very little into the wing. Hindwings yellow with a faint rosy tint; abdomen above purple-red, below white.

N. sardinapalus Rothsch. (46 f). Smaller than the preceding, recognizable by the yellow costal spot *sardinapalus* of the forewing and particularly the marginal yellow being strongly confined, widening scarcely appreciably between the median veins. Upper Amazon and Peru.

N. tremula Schs. (= *subgaudialis* Rothsch.). Easily recognizable by the brownish-grey forewings *tremula*, being vividly marked with small transverse streaks. Before the middle of the costal margin a small, sacciform, yellow spot, and a similar coniform spot above the anal angle of the forewing. Hindwings scarlet like the abdomen above. Size of *cotes*. French Guiana.

N. cardinalis Dgn. (46 e). Body and wings purple pink. Forewing with an antemedian, whitish- *cardinalis*, yellow transverse band being narrower in the ♀, and whitish-yellow triangular spots behind the middle of the costa and above the anal angle; also in the apex a similar small spot of a variable size. Colombia (Muzo).

N. steniptera Hmps. (= *basalis* Rothsch.) (46 f). Forewings coloured as in *tremula* and indistinctly *steniptera*, striated; in the basal part yellow embeddings marked red, above the anal angle small, bone-white spots. Hindwings yellowish, marginal half dull black. Guiana to Bolivia.

N. ockendeni Rothsch. (46 f) greatly approximates *steniptera*, but it seems to fly in the same district *ockendeni*. (Guiana to Peru); forewings somewhat more distinctly spotted, and the dark marginal band of the hindwings narrower.

N. holophaea Hmps. (46 g). Unicolorously sooty black, abdomen and hindwings faintly reflecting *holophaea*, bluish. Only the male scent-pencil on the under surface is white. French Guiana. By its exterior being unicolorous, it resembles numerous Aretiids and Syntomids of its range.

- nigricollis*. **N. nigricollis** Dgn. (46 g). Body and forewings quite similar to *holophaea*, also the blue reflection of the hindwing is present, but the hindwing is white as far as beyond the middle. Ecuador. Like the preceding it resembles numerous Syntomids and Arctiids.
- flavibrunnea*. **N. flavibrunnea** Dgn. Smaller than *nigricollis*, forewings red-brown as in *steniptera* (46 b), but without distinct spots, with light veins. Easily recognizable by the hindwing showing a light central area, from which a yellow light patch extends through the cell towards the base. French Guiana.
- abdominalis*. **N. abdominalis** Roths. (46 g). Dark brown, forewing with light veins and a whitish spot below the cell-end; vertex and posterior half of abdomen yolk-coloured. Upper Amazon.
- discophora*. **N. discophora** Hmps. (46 g). Twice as large, head, collar, and the whole abdomen yolk-coloured. Forewing with a larger, round disc behind the cell, and the hindwings in the middle whitish. Peru.
- sorex*. **N. sorex** Drc. (46 g) is almost exactly like the preceding, the spot of the forewing, however, elliptical and hyaline, the hindwing in the costal region whitish. Peru and Bolivia.
- leucoplaga*. **N. leucoplaga** Hmps. (46 g). Distinguished from the preceding by the abdomen being above dark brown. French Guiana.
- prophaea*. **N. prophaea** Schs. (46 g). Much smaller than the preceding, particularly the hindwings are small; wings dark brown, only the analmarginal area and the hindwing yellowish-pink, so is the vertex and dorsum of abdomen as far as towards the apex. French Guiana.
- eximius*. **N. eximius** Roths. (46 g). Only as large as *prophaea*, thorax and forewings dark brown with purple markings on the collar, patagia and near the base of the forewing; from there as far as beyond the middle of the forewing hyaline. Hindwing dark brown with a hyaline centre and purple at the proximal margin. Peru.
- flavipurpurea*. **N. flavipurpurea** Dgn. (46 g). Black, forewing with a broad golden yellow oblique band from the middle of the costa towards the anal angle. Hindwings and abdomen with a dull blue reflection. Colombia; discovered by A. H. FASSL near Muzo.
- chrysozona*. **N. chrysozona** Schs. Much smaller, the orange-yellow oblique band narrower, hindwings blackish-brown, but without the blue reflection. Easily discernible from the preceding by a cuneiform basal ray in the middle of the hindwing. French Guiana.
- maculosa*. **N. maculosa** Schs. The type of this species unknown to me in nature, from French Guiana, is in the National Museum at Washington and seems to have remained unique. It deviates from all the others of the genus by the thickened and woolly haired hindlegs and the plain antennae of the ♂. Forewings yellowish-white, thick, dark internerval streaks in and behind the cell, from the cell-end as far as 2 or 3 mm before the border; finer and shorter ones before the middle and at the end of the submedian space. Hindwings yellowish-white, below the cell strewn with a dark colour. Size of *flavipurpurea* (46 g), but the forewings broader and the hindwings smaller. Thorax dull greyish-brown, head and abdomen orange.

40. Genus: **Hyponerita** Hmps.

To this genus 16 species have so far been reckoned, being like the preceding genera confined to the northern parts of South America and the southernmost part of Central America. All the species represent variegated, elegantly marked forms often repeating the images of *Nerita* and *Paranerita*. They also, except one, have been discovered of late and vary very little: like in the *Ithomiinae* resembling them in the homoechromy of parallel genera, ample collections of specimens from the same district may be examined without finding the least deviations. Nor is there a geographical variation known in the genus. Whether it is itself a natural one, we have already doubted above, and these doubts are increased by the fact that e. g. a very peculiar and extreme specialization of the hindlegs appears in a *Hyponerita* (in *rhodocraspis*), not recurring in any other species of the genus, but in a *Paranerita* (in *P. haemabasis*) (45 l). Like the *Paranerita*, the *Hyponerita* have an accessory cell being produced by the 2nd subcostal vein, which is sent out from the 1st, anastomosing with the 3rd. Otherwise the *Hyponerita* entirely resemble the preceding genera; nor do they differ by the border of the hindwing being also retracted below the apex, by the scent-organ in the submedian space on the hindwing beneath, or by the antennae being mostly provided with entirely white tips. The larva is not yet known of any species, but we may expect brushy larvae with long hair-pencils at both ends.

- viola*. **H. viola** Dgn. (46 h) repeats the colouring so often recurring in the preceding genera, of *Neritos macrosticta* (46 d), *Paranerita inequalis*, *Neonerita perversa* (45 h) and others. Apical disc and inner-marginal half of the forewing uniformly violettish-brown, the rest of the wing, as well as the hindwing and abdomen honey-coloured. Guiana.

H. tipolis Drc. (= *viola borealis* Rothsch.) (46 h). The band separating the apical disc is much broader *tipolis*, and more hyaline than yellow. Thereby it resembles more a *Neritos drucei* (46 c). Southern part of Central America and Colombia; the figured specimen from Villavieeneio.

H. lucens Schs. (46 h) is nearly exactly like the preceding species, but the dark parts in the forewing *lucens*, are deep dark violettish-brown instead of light purple brown. French Guiana.

H. interna Schs. (46 h) is easily recognizable by the purple red abdomen and by the dark apical *interna*, spot being removed from the margin, but situate on the costa. French Guiana.

H. klagesi Rothsch. (46 h). The discous spot before the apex is at the apex itself pushed back by a *klagesi*, smaller spot of the yellow ground-colour; it is contingent with the dark inner-marginal spot by a narrow bridge. The latter spot from the direction of the proximal margin lighter, bluish-white. From Fonte Boa on the Amazon.

H. rhodocraspis Hmps. (46 h) represents a parallel form to the *Neritos* of the *cotes*-group (46 f) and *rhodocraspis*, to the *Paranerita* of the *niobe*-group (46 a). The ♂ hindlegs are much longer and, by means of sprawling hair-brushes, transformed into woolly paws. Colombia and Peru; the figured specimen from Villavieeneio (Coll. FASSL).

H. ockendeni Rothsch. (♀ = *ockendeni* posterior Rothsch.) (46 h) has much broader wings than the *ockendeni*, preceding which it otherwise resembles. The tooth of the marginal area projecting into the forewing is here placed higher than in *rhodocraspis*, the ♂ legs not conspicuously changed. Venezuela, Peru.

H. tramoia Joicey. Size of *ockendeni*; the yellow spot of the middle of the costa extends along the *tramoia*, costal margin towards the base and to the apex; the marginal yellow from the apex almost to the anal angle projects proximally on the uppermost median. Hindwing yellow, the inner-marginal part slightly tinged pink. Abdomen purple-red. Colombia.

H. carinaria Schs. (46 i). The yellow costal triangle and the small spots of the middle of the border *carinaria*, on the forewing very small; hindwings yellow, tinted reddish. French Guiana.

H. incerta Schs. (46 i) very closely allied to *carinaria*, the small costal spots not larger, but the marginal *incerta*, yellow in the forewing more extensive. Forewings more pointed, hindwings smaller, more intensely tinged red. French Guiana.

H. declivis Schs. (46 i) is one of the smallest species; forewings almost like in *incerta*, but still darker; *declivis*, hindwings still smaller than there, yolk-coloured, not red. French Guiana.

H. furva Schs. (46 i). All the wings quite unicolorously dark brown, only at the border of the forewing *furva*, some yellow, like the apex of the abdomen. Costa of the hindwing somewhat ochreous. Surinam.

H. similis Rothsch. (46 i). Yellow; forewings with rows of small hemochrome, guttiform spots flown *similis*, together to clouds; they give room to an antemedian transverse band and torn up groups of spots in the distal half of the wing. Head and body hemochrome, marked yellow. Hindwings pale yellow. Guiana and Amazon.

H. lavinia Drc. (46 i). The red on the hindwing increased so much that it only admits yet a yellow *lavinia*, antemedian chain, some traces at the base and few small spots in the distal area. Body hemochrome; hindwings pink. Guiana and Colombia.

H. persimilis Rothsch. (46 i). Here the yellow appears more in spots as costal triangles and as an irregu- *persimilis*, lar, light cloud above the anal angle. In the ♂ the hindwing and abdomen are yellow, in the ♀ tinged purple red. Widely distributed; from Guiana across the Amazon to Peru; the figured ♀ from the Upper Rio Negro.

H. pinon Drc. (46 i). The largest species of the genus. It distinctly repeats the colouring of a *Melese pinon*, *peruviana* (43 e); but on the forewing there is in the middle of the submedian vein another yellow spot. Hindwings of a deeper red. Santos in South Brazil.

41. Genus: **Parevia** Hmps.

This genus, composed of 13 species, likewise belongs yet to those genera resembling in their exterior such genera that do not exclusively belong to the Aretids; the *P. syntomioides*, for instance, derives its name from its resemblance to certain *Syntomidae*, such as the *Dycladia*-species (from the affinity of *D. xanthobasis*, 28 d). — All the species of the genus are very small; some have an expanse of scarcely 15 mm. From *Evius*, which the genus resembles in the venation of the forewing, it deviates by the subcostal coming from the upper angle of the cell of the hindwing mostly bifurcating before the margin. In the forewing there is no areola. Sometimes, however, also the ♂ hindwings are changed by scent-organs in such a way (*lobata*), that the course of the veins becomes quite abnormal.

- paruelli*. **P. parnelli** Schs. (46 k). From Costa Rica; it has violettish-brown forewings marked red above the proximal margin, with yellow costal triangles at the costa and at the border above the anal angle; hindwing yellow with a broad, black marginal band. Posterior femora of the ♂ very stout. The figured specimen from the Orosi.
- metachryseis*. **P. metachryseis** Hmps. (46 k) is quite similar, the yellow spot in the middle of the costa smaller, that above the anal angle larger; in the hindwing the whole distal half is black. Guiana.
- guianensis*. **P. guianensis** Joicey is also similar, but smaller, and the hindwings are above red-brown, at the proximal margin narrowly yellowish. British Guiana.
- mathani*. **P. mathani** Roths. (46 k) is of a lighter colouring, the yellow spots of the forewing at the costa and border enlarged and some more yellow spots above the proximal margin and at the base. Hindwing yellow with a black marginal band. From Teffé (Ega) on the Amazon.
- methaemia*. **P. methaemia** Schs. (46 k). A very small species; the yellow spots on the forewing are small and reduced in number, hindwing purple-red without a marginal band. Guiana.
- affinis*. **P. affinis** Roths. (46 k). Forewings unicolorously brownish dusty-grey, hindwings pink, costa, costal margin and apex dark grey; middle of the abdominal dorsum pink, too. Colombia to Guiana and Brazil.
- sisenna*. **P. sisenna** Drc. is almost exactly like *parnelli* (46 k), but the yellow costal spots are quite small, the hindwings are red instead of yellow, and their whole distal halves black. Espiritu Santo, and Peru.
- cinerea*. **P. cinerea** Roths. Size of the preceding, but the hindwings larger and longer. Quite dirty brownish-grey, wings at the border darker; the forewing also at the cell-end darker, above the end of the proximal margin before the border somewhat lighter. Fonte Boa in the Amazon District.
- griseotincta*. **P. griseotincta** Roths. (46 k). Only the size of *methaemia*, but the forewings dark brown without spots and the hindwings unicolorously blackish-brown. Surinam.
- schausi*. **P. schausi** Roths. (46 k). Dull straw-coloured with darker transverse bands of the forewings before and behind the middle, between them fainter yellow lines. A somewhat larger species; Fonte Boa (Amazon).
- griseata*. **P. griseata** Roths. (46 k) from the same district as *schausi*, but smaller, the forewing greyish with whitish veins and small white spots, placed in the shape of a Y, enclosing the cell-end; hindwing white with a narrow brownish border. It somewhat resembles several *Syntomidae* (*Eucereon*).
- syntomoides*. **P. syntomoides** Roths. (46 k) entirely resembles certain *Syntomidae* (*Dycladia*). Forewings with ante- and postmedian, discal vitreous patches, hindwings yellowish with a narrow black border. Surinam.
- lobota*. **P. lobota** Dgn. resembles certain Arctiids (*Premolis*, *Prumala*, *Eupseudosoma*); the bright, yellowish-red forewing exhibits a light yellow distal-marginal part, extending semicircularly from the border below the apex along the costa and discocellular and then towards the anal angle. Easily distinguishable by the very small whitish hindwing of the ♂, with a very short costal margin and twice as long proximal margin, the latter being tinted pink above and exhibiting a short scent-fur beneath. Size of *schausi*. Colombia.

42. Genus: **Haplonerita** Hmps.

Based upon 1 male butterfly. Distinguished from the preceding genus by the areola in the forewing, from the other allied genera by the strongly angled discocellular in the (very large) hindwing. The genus is presumably naturally allied to *Araeomolis* or *Hyperandra*.

- simplex*. **H. simplex** Roths. (43 c). Body and wings quite purple, the forewings darker with a yellow border being narrow in the middle, the hindwings lighter, more pink. Surinam.

43. Genus: **Schallotomis** Hmps.

The two species for which HAMPSON established the genus, have very little in common, and their affinity would first have to be proved. Both are remarkable for the early bifurcation of the subcostal in the hindwing, and for the absence of the areola in the forewing; in *roseothorax*, however, the median veins are distorted to such an extent that the lower one, at its rise, takes first the direction towards the middle of the submedian, then turns towards the border and terminates at the border quite close at the termination of the submedian. In the palpi the terminal joint is almost as long as the middle one. In the second species (*curta*) we do not find this anomaly of the venation, and the terminal joint of the palpus is rudimentary; here, however,

the ♂ hindwing is extracted into a long, furry anal lobe. — The two species have been described by LORD ROTHSCILD only in 1917; the first as *Diarhabdosia*, the second as *Hyponerita*. Neither of the species is known to me.

S. roseothorax Rothsch. ♂ 24, ♀ 30 mm. In the shape in fact somewhat like a Lithosiid, the long *roscolthorax*. extended forewing reddish-brown with a narrow, white stripe each close below the costal margin and close above the proximal margin. Hindwing white, at the border slightly brownish. Peru.

S. curta Rothsch. (26 mm). Forewings coloured and marked about similarly as in *Paranerita peninsulata curta*. (46 a), but the hindwings light yellow, only in the costal area tinted reddish, with an oblong anal part showing on the under surface a felt-like cover in the submedian space. Guiana.

44. Genus: **Antaxia** Hmps.

Described as a Syntomid genus by the author and only later on reckoned among the Arctiids, together with the genus *zatrephes* Hbn. closely allied to the *Antaxia*. Closely allied to the *Automolis*; distinguished from the preceding genera by the absence of the subcostal (free costal) in the hindwing. Palpi short and stout, with dense hairing. Cell of the hindwing obliquely defined, the lower cell-wall longer than the upper one. Except 2 species, all the *Antaxia* have rather long-combed antennae. 11 species in Tropical America, to the north as far as Mexico.

A. similis Rothsch. (46 l). The dark apical spot of the forewing is connected with the brown of the *similis*. inner-marginal area by a chain of spots; in the said brown a small, yellow, round spot below the cell and a crescentiform yellow spot above the middle of the proximal margin are embedded; abdomen hemochrome. Peru.

A. pyrgion Drc. (46 l) greatly resembles the preceding, the connection of the apical spot with the basal *pyrgion*. brown of the forewing is only produced by some very fine, small dots. The hindwing has a bright red proximal half and exhibits above the anal angle a grey nebulous spot parted by the veins. Panama and Costa Rica, on the Volcano Irazu.

A. meridionalis Schs. (46 l) is lighter coloured than the preceding; the whole basal part of the forewing *meridionalis*. except one fourth light yellow, the brown above the proximal margin brightened up by violettish-white embeddings, the yellow spot at the middle of the proximal margin extended to a longitudinal stripe, the hindwing of a purer white, at the proximal margin only quite pale pink and without the nebulous spot. Peru.

A. creon Drc. Forewings again as in many *Idalus*, *Prumala*, *Neaxia* etc. divided into a dark basal *creon*. and a light yellow apical half. From the apex emerges an oblong oblique spot being strangulated in the middle and encircled by hemochrome, not being connected with the basal brown. Near the base below the costa, a small yellow longitudinal spot is embedded in the brown. Hindwing in the anal part tinted pink. 40 mm. Mexico.

A. primulina Dgn. (46 l). Nearly the whole forewing purely light yellow, only the apical spot is yet *primulina*. brownish, the costa and small, feeble spots round the middle of the cell; hindwings purely white. Colombia.

A. collaris Jones (46 l). In this species being one of the few of this genus with almost plain antennae, *collaris*. quite contrary to the preceding, the brown is strongly increased, so that the apical spot is connected with the brown of the inner-marginal area by a thick band. Hindwings purple pink, at the border blackish spots. In the ♀ the thorax and hindwings are tinged more purple than brown. Santos in South Brazil.

A. apiciplaga Rothsch. (46 l). Quite purple pink; on the forewing a broad yellow band, beginning *apiciplaga*. directly below the costa, extends to the middle of the border and cuts off a circular apical spot from the ground-colour. Fonte Boa on the Amazon.

A. dichroma sp. nov. (46 l). Like *apiciplaga*, but the yellow band separating the apical spot is twice *dichroma*. as broad and somewhat diaphanous in the middle; hindwings lighter. From Mount Tolima in Colombia; discovered by FASSL.

A. flavomarginata Rothsch. resembles about some *Paranerita*; forewing purple brown, the costa, a *flavomargi-* triangle behind the middle of the costal margin, and the border broadly yellow. Hindwings pink with yellow *nala*. fringes. Fonte Boa (Amazon).

A. abdominalis H.-Schäff. (46 m). Light yellow, head and thorax orange, marked black. Forewing *abdomina-* yellow with ochreous veins, and fine, interrupted black streaks between; at the cell-end an orange crescent *lis*. surrounded by black; behind it an undulate transverse stripe bending far outwards behind the cell; an ante-marginal, broad, orange-yellow band with a row of dark dots; hindwings semi-diaphanous, at the proximal margin tinged orange; abdomen orange. South Brazil.

A. hyalina Rothsch. (46 l). Body and base of forewing orange-yellow, through the middle an obliquely *hyalina*. curved transverse band filled up with blue, encircled and marked with black, behind it a transparent spot before

the darkened, greyish-brown marginal part. Peru, Costa Rica, on the volcano Irazu; in specimens from there the anal part of the border in the hindwing is brownish. — *amaculata* Rothsch., described from Colombia, has the border not covered with brown; but there are also specimens from the Orosi in Costa Rica, taken together with typical ones. — On the contrary, however, specimens from the Rio Songo in Bolivia show the black shading increased and extending into the hindwing.

45. Genus: **Eupseudosoma** Grt.

About 12, not homogeneous forms compose this genus. One group, being the typical one, has snow-white butterflies with a hemochrome abdomen. The larvae are wrapped up in a dense fur, in which they stick like in a sack from which the head looks out; the head, however, is again crowned by bownet-like projecting brushes. The pupa is red-brown encased in an oviform furry cocoon. In this division the subcostal of the hindwing bifurcates before the cell-end. In the second division we find variegated butterflies, scantily haired larvae, a loose cocoon, and in the ♂ hindwing the subcostal bifurcates behind the cell-end. The ♂♂ of the first division have also more pointed forewings, those of the second such with a rounder border. The first division is probably allied to the Syntomids, the second more to the genuine *Arctiinae*; at any rate it is a mixed genus.

A. Butterflies snow-white, mostly with a hemochrome abdominal dorsum.

- involuta*. **E. involuta** Sepp (= *floridum* Grt., *immaculata* Graef) (50 a). Wings white with a satin gloss, only the apical part of the costa of the forewing with a very fine black cover. In the ♀ mostly an extremely fine, somewhat curved longitudinal streak, appearing black only in a certain exposure to light, runs through the whole submedian space of the forewing. On the abdomen the dorsum is hemochrome, the 3 last segments, the base and a minute median spot behind it are white, behind it often yet minute white dorsal dots. — In *flavida* *Dgn.* from French Guiana the abdomen is above orange-yellow. — *nivea* H.-Schäff. (50 a) has more purely white, less diaphanous wings, and on the red dorsum of the abdomen there are small white transverse bands. On the forewing, beside the submedian ray, another dark streak runs from the transverse vein to the border. — *agramma*. **agramma** Hmps. (= *involutum* Drc. p. p.), according to its author a distinct species, is somewhat smaller, the forewing without the black costa, the ♂ with smaller hindwings. — Larva in a dense furry cover by which it is sacciformly surrounded and which may be red-brown, grey, orange-yellow, even velvety black. On the 2nd and 3rd ring there are whitish pencils projecting in front beyond the head. On *Psidium pyrifera*, *Eugenia buxifolia* and *E. procera*. The species is widely distributed, from Florida to South Brazil; *agramma* described from Mexico. The butterfly likes to come to the lantern and is in some places not rare; in Guiana it leaves the pupa already on the 9th day.
- aberrans*. **E. aberrans** Schs. (50 a), from South Brazil and Paraguay, is quite similar, but the costa of the forewing much more intensely dark brown, and the inner-marginal part of the ♂ hindwing often intensely tinted pink.
- bicolor*. **E. bicolor** Rothsch. (50 a) from Colombia (Santa Marta) has the abdomen red almost to the apex, the thorax being marked red, the forewing at the costa yellowish and at the base at the proximal margin tinted pink; the discocellular is very finely dotted black. Hindwings purely white; very closely allied to *involuta*.
- grandis*. **E. grandis** Rothsch. (50 a) from Peru is recognizable by the large size, the purely white wings and the prothorax being marked yellowish.
- nigropunctata*. **E. nigropunctata** Rothsch. (50 a). White, the forewing with black punctiform spots in and below the cell and before the apex, near the border; costa profusely blackish-brown; abdomen not red but above white, faintly tinted yellowish-brown. Amazon: Fonte Boa.

B. Wings variegated, not white.

- bifasciata*. **E. bifasciata** Cr. (50 a). Purple brown, with lighter patagia. Body and wings in some places reddish; forewing with 2 ante- and postmedian dark lines parallel to the border. Surinam. — *eurygania* Drc. is the form from the Chiriqui in Panama, more yellowish-brown, without the red tinge. — Larva scantily short-haired, black, with lateral and subdorsal bands composed of numerous white dots head yellowish-brown, ventral feet and their ramifications light reddish; on coffee.
- affinis*. **E. affinis** Rothsch. (50 b) from Peru is rather exactly like a small *Neonerita syriassa* (45 h) which is often repeated in the South American Arctiids (e. g. in *Zatrephes pseudopremolis*), the basal half of the forewing purple-brown, apical half diaphanous light yellow, costa and a small costal spot before the apex purple brown; hindwing whitish-yellow, inner-marginal part tinted purple.

E. marpessa Drc. (50 b) is quite similar, the purple of the basal half more extensive; the small preapical *marpessa* spot larger. Likewise from Peru.

E. parapessa Dgn. (50 b), from the same district as the preceding, has $\frac{3}{4}$ of the forewings purple, *parapessa*, which colour extends at the costa broadly to the apex; only the marginal area, proximally bordered with an irregularly undulated, dark line, remains diaphanous.

46. Genus: **Premolis** Hmps.

This genus of which 5 species are described has, like the last division of the *Eupseudosoma*, no uniform character owing to imitations from other genera. Remarkable is the small proboscis, the entirely rudimentary palpal terminal joint and above all the strong antennal teeth being thickened towards the ends. Forewing without an areola, the 1st subcostal vein branches off directly before the upper angle of the long, cuneiform cell of the forewing, the upper median with the lowest radial veins almost simultaneously from the lower cell-angle. The species seem not to be common.

P. flavithorax Roths. (50 b). Parallel form of *Prumala pyrostrota* (44 i). The violettish-brown basal *flavithorax* half is bordered with purple red and sinuately defined towards the yellow distal area in which there are 4 black dots between the veins. Abdomen vermilion. Amazon District.

P. ridenda Dgn. (50 b) from Guiana is a form parallel to *Eupseudosoma marpessa*. The purple brown *ridenda* of the basal half of the forewing extends as a costal band along the costal margin and bends round towards the margin at the apex in a hook.

P. rhyssa Drc. (50 b) is quite similar, larger, the costal stripe in the apical half very dark blackish-*rhyssa* brown, in the purple brown part of the wing whitish embeddings surrounded by dark. Peru.

P. semirufa Wkr. (50 b) is a large species resembling somewhat *N. minerva* (44 h); in the distal *semirufa* half of the forewing a hyaline yellow band being very broad at the costa, ending only half as broad at the border, extends in front of the apex. In this band the veins are dark, the spaces between dotted red. Hindwings pink, towards the costa lighter. Panama and on the lower Amazon, as well as Peru.

P. amaryllis Schs. is the smallest species. Still smaller than *flavithorax* (50 b). Head and thorax *amaryllis* yellow, marked red. Forewings honey-coloured, the costal margin broadly red-brown; behind the cell, from this costal band a similarly red-brown, equally broad, straight band runs towards the proximal margin which it touches just at the anal angle. Hindwings yellow with a red hue; abdomen orange. 32 mm. From French Guiana. The type in the National Museum at Washington.

47. Genus: **Automolis** Hbn.

In this genus HAMPSON combines more than 12 other genera, with about 200 forms. The very name of this collective genus offers difficulties, since the typical species is doubtful, although the imago, larva, pupa and cocoon are figured. The single groups of the genus are certainly rather little allied to each other, as we see already from our superficial knowledge of their early stages. The first divisions show as larvae distinct relations to the Syntomids, but also to the *Pelochya* which are perhaps neither genuine Arctiids. The *rutilus*-group has unmistakable *Halisidota*-larvae, and others again emerge from larvae scarcely differing from the common *Arctia*-larval form provided with uniform hair-tufts. — In the way as the genus is at present composed, chiefly according to the venation being unreliable in the Arctiids, it contains the most heterogeneous formations: large and small, clumsy and slender species, angled and entire-margined forewings; small, stunted hindwings and also such showing no abnormality whatever; the venation itself also often deviates considerably; the hindwing has sometimes 7 (*sanguinolenta*) sometimes 8 (*ventralis*) veins; the subcostal vein of the hindwing may branch off far before the cell-end, or also only at it; furry spots may be absent or present in the ♂, on one wing (*larissa*) or on both (*semiopalina*). The antennae also vary in length. On the whole, the genus makes the impression of being an assortment of species rather remote from one another, which will be dissolved into a greater number of genera later on, when more females and larvae will be known. We must here restrict ourselves to mentioning the few characteristic marks being common to most of the species and arrange them one after another in such a way that the colourings may be denoted with but few words and be developed one from another.

Head rather large with thick round eyes; palpi rising, the terminal joint mostly short, often quite rudimentary, sometimes also long (*semiopalina*); proboscis always strong. On the forewing the lower median vein always rises far before the cell-end, the upper median vein emerges from the lower cell-angle and the uppermost

(last radial) comes from the same place, but it may also branch off yet before the cell-angle. The 2nd radial comes from the upper cell-angle, the subcostal veins 2 to 5 with a common footstalk, the first rising from the upper cell-wall, sometimes close sometimes farther before the cell-end. Hindwing sometimes entire-margined, sometimes retracted below the apex, in the ♂ sometimes costally (*herois*) or also anally (*reducta*) lobated; cell almost invariably of exactly half the length of the wing. Nearly all the butterflies are very conspicuously variegated and very beautifully marked species, some with metallic colours on their body. The larvae often have brush-shaped pads on the 5th and 11th rings or woolly transverse puffs, before or behind them long pencils formed of few bristles; otherwise they are short-haired. Some live on trees (*Psidium pyrifera*) and are not easy to breed. The butterflies come to the lantern at night and many appear to be very rare; most of the species have been discovered during the last years.

- sypilus*. **A. sypilus** Cr. (50 c). The orange longitudinal band of the forewing is broad at the base of the wing and terminates pointed behind the cell; before the apex a spindle-shaped, orange-yellow oblique spot. Hindwing in the costal part orange. Abdomen with an orange transverse streak on the 1st and 2nd rings, the posterior half black with metallic blue dorsal and lateral spots. — Larva dark brownish-grey with a light dorsal and lateral stripe and an ochreous brown head, on the 5th and 11th rings there is a yellowish-brown dorsal brush, similar to that of an *Orgyia*-larva, but above rounded off, behind each of these brushes 4 to 6 very long white hair-pencils. Pupa yellowish-brown, in an oviform, Syntomid-like, grey cocoon intermixed with hair. Surinam.
- sypalettius*. **A. sypalettius** sp. nov. (50 c). Only half the size of *sypilus*; the small apical band almost forms the continuation of the yellow basal ray ending taperingly soon behind the cell-end. From Villavieencieio (Colombia); type in Coll. FASSL.
- metallica*. **A. metallica** Joicey (50 e). Head and body above blackish-brown, vertex and abdominal dorsum spotted metallic blue. Forewing greyish-black with yellow-streaked veins, below the cell a yellow stripe as far as into the disc, and before the apex a small yellow spot; hindwing black with an orange costal spot. The patagia are always striped orange, but the abdomen only sometimes at the base yellow; the orange stripe in the forewing may be more intense or fainter. From Colombia and the Chiriqui.
- packardi*. **A. packardi** Btlr. (= *sypilus* Wkr. nee Cr.) (50 c) differs by the quite black abdominal dorsum, almost entirely black thorax, narrower orange stripes of the forewing, the preapical one of which is prolonged like a band; hindwing in the costal part lighter, but not orange. Amazon; Pará, Teffé.
- saturata*. **A. saturata** Rothsch. (50 c). Body above quite feeble with a narrow, yellow patagial margin; longitudinal stripe of the forewing narrower and much more curved, hindwing with a yellow costal half. Perhaps the ♂ of *sypilus*. Guiana, Santa Catharina.
- neira*. **A. neira** Schs. (50 c) only differs from *saturata* by the small, preapical, orange band of the forewing being placed more steeply. Rio de Janeiro.
- sphingidea*. **A. sphingidea** Perty (= *vittigera* Fldr.) (50 c) is immediately recognizable by the orange band extending into the apex of the forewing itself, not to the border below it. Amazon.
- ataenia*. **A. ataenia** Schs. (= *collateralis* Rothsch. nee Hmps.) (50 d) is much larger and stouter, the longitudinal band of the forewing ends in the upper third of the border. In the ♂ the stripe of the forewing is narrower and its end does not pierce the fringes; costal part of the hindwing yellow, in the ♂ the apex is black. Amazon District from the Rio Negro to Pará. — In **rosenbergi** Rothsch. (50 d) from Venezuela and Ecuador the longitudinal stripe of the forewing ends 2 or 3 mm before the border and the apex of the hindwing is broader black.
- taeniata*. **A. taeniata** Guér. (= *sphingiformis* Clem., *imitata* Drc.) (50 d). The orange stripe of the forewing is broader, but not curved, but straight. Abdomen orange with a black dorsal stripe. Mexico to Costa Rica; one of the most common species of the genus.
- underwoodi*. **A. underwoodi** Rothsch. (50 d). Longitudinal stripe of the forewing more than twice as broad as in the preceding; abdominal dorsum posteriorly quite black. Costa Rica.
- guapisa*. **A. guapisa** Schs. (50 d). The longitudinal stripe of the forewing is quite thin and dull dark orange, besides the veins are very finely marked orange. Costa Rica.
- pseudoguapisa*. **A. pseudoguapisa** Rothsch. (50 d, e). The yellow median stripe of the forewing is in the ♂ only quite thin and in Peruvian ♀♀ only yet noticeable in the basal third of the forewing. Venezuela, Peru. — Distinguishable from the preceding by the abdominal dorsum being above quite dark, the basal part of the abdomen in *guapisa* showing lateral yellow spots.
- fulgurata*. **A. fulgurata** Btlr. (50 e). The yellow band of the forewing extends broadly as far as behind the cell-end, but then it ends pointed into the propinquity of the border. The veins are quite faintly marked yellow. South Brazil.

A. melea *Drc.* (50 e). The band of the forewing is quite straight and at the end rather broader than *metea*, at the base. Venter beneath with yellow transverse bands on the rings 1 to 6. In the yellow costal region there is below the middle of the costa in the ♂ a small black spot being absent in the ♀. Venezuela, Upper Rio Negro.

A. maura *Schs.* (50 e). Above almost exactly like *melea*, but recognizable by the abdomen beneath *maura*, not being banded yellow, but black, with metallic blue spots. Costa Rica.

A. collateralis *Hmps.* (nec *Rothsch.*) (50 f). Band of the forewing much broader than in the prece- *collateralis*. ding; recognizable by the entirely orange-yellow patagia. Besides the border of the forewing is tinged orange. Colombia.

A. pratti *Drc.* (50 e). The orange band of the forewing is so much widened that only the margins *pratti*. remain blackish-brown. Colombia.

A. tanialoides *Rothsch.* (50 e). The orange area of the forewing extends in its whole length as far as *tanialoides*. the costa, so that only in the apical part the costal margin remains yet very finely black. At the sides of the abdominal base 1 small orange spot each. Costa Rica.

A. taniala *Schs.* (50 e) almost exactly resembles the preceding above, only the small orange spot at *taniala*. the abdominal base is absent and the costal part of the hindwing is not quite so extensively yellow. Venezuela.

A. latania *Drc.* (50 f). Forewings quite orange, only the distal margin quite narrowly black, extending *latania*. round the apex and proximal angle. Abdominal dorsum at the base with yellow lateral spots; venter with orange transverse bands. Colombia, Upper Rio Negro, Venezuela. — In the form **vulcanica** *form. nov.* (50 f) *vulcanica*. the yellow ventral bands are reduced to 2 small spots and the yellow lateral spots at the base of the abdominal dorsum are absent altogether. At the proximal margin of the forewing a jet-black wedge-shaped spot; from the volcano Irazu in Costa Rica.

A. nabdalsa *Schs.* (50 f). Orange; forewing with black streak-spots along the costal margin and bet- *nabdalsa*. ween the veins in the marginal area. Border of the hindwing narrow black. End of abdomen black, spotted lustrous blue. Mexico, Vera Cruz; apparently rare.

A. opposita *Wkr.* (= *ochrophila* *Fldr.*) (50 f) has always an orange basal part of the abdomen. Fore- *opposita*. wing with an oval orange spot behind the middle of the costa, extending towards the anal angle, and with another one from the lower cell-angle towards the middle of the proximal margin; the veins streaked light. Hindwing orange with a marginal band growing broader towards the proximal margin. Still smaller than *nabdalsa*. Apparently very rare. Amazon and Guiana. The type in the British Museum.

A. chrysomelas *Wkr.* (= *geometrica* *Fldr.*) (50 f). Forewing orange-yellow, divided into 2 areas *chrysomelas*. by a black ray from the base being bent round at the cell-end and extending above the anal angle into the border. Guiana, South Brazil.

A. sicilia *Drc.* (= *parma* *Schs.*) (50 f). Orange; forewing with a white apex encircled by black, *sicilia*. hindwing with a blackish border. Mexico, Central America, and Colombia.

A. contraria *Wkr.* (50 g). Smaller, otherwise quite similar to the preceding, but the white apical *contraria*. spot much broader encircled by black. Colombia and Amazon District.

A. albimaculifera *Hmps.* (50 g). Like *contraria*, but the costal margin of the forewing broad blackish- *albimaculifera*. brown. Manicoré (Amazon).

A. zenzeroides *Btlr.* (50 g). Orange, the dark apex of the forewing contains 2 light pupils; at the *zenzeroides*. border above the anal angle a small, dark spot. Rio Purus (Amazon).

A. orbona *Schs.* (50 g). Orange, the forewing with a dark apex, which, however, has no white pupil; *orbona*. before the border some small, dull nebulous spots. Hindwing yellow with small dark marginal spots. Mexico (Vera Cruz).

A. bonora *Schs.* (50 g) entirely resembles *orbona*, but the apex of the forewing only very narrowly *bonora*. encircled by black; at the border of the hindwing only 2 very small black dots. French Guiana.

A. ochreomarginata *Joicey.* Like the preceding species orange, but the abdomen already from the *ochreomarginata*. 3rd ring blackish-brown with blue lustrous spots on the dorsum of the 3 last rings; the forewing have only at the apex dark brown fringes, the hindwing is pale orange. French Guiana.

A. sulfurea *Schs.* (50 g). Likewise yellow, but here the thorax and forewings are pale yellow, the hind- *sulfurea*. wings orange; the latter with a black marginal band from the anal angle to beyond the middle of the border. Abdomen beginning from the 4th ring black, spotted blue. French Guiana.

- salma*. **A. salma** Drc. (= *superba* Hmps. p. p.) (50 g). Sulphureous, forewing with a minute black spot before the anal angle; abdomen orange, at the end a dark, lustrous blue dorsal spot. The ♀ has also at the anal angle of the hindwing a small dark spot. Central America. — In the quite similar **superba** Drc. (50 g) from Colombia and Ecuador the small spot of the forewing is more intense and the hindwing paler orange-yellow; besides another black apical dot in the forewing and black dusting at the middle of the border of the hindwing.
- pauperis*. **A. pauperis** Schs. (50 h). Yellow, the forewings orange, without any small black spots, the hindwing in the disc pale diaphanous. Apex of abdomen blackish. The hindwing are much larger than in *salma*, the shape more squat. Costa Rica.
- fassli*. **A. fassli** Dgn. (50 g). Quite orange, the apex of abdomen neither black; the hindwing only in the costal half lighter. ♂ hindwing with a pointed anal lobe. From San Antonio in Colombia.
- virescens*. **A. virescens** Rothsch. (50 h), like *fassli*, deviates considerably in the shape from the other *Automolis*, and according to HAMPSON's investigations it belongs into the genus *Hypomolis*, near *H. ockendeni* and *H. rothschildi*. Unicolorously pale green, only the costa of the forewing and fringes orange; abdomen and inner-marginal area of the hindwing sulphureous. Peru.
- leucoptera*. **A. leucoptera** Hmps. (= *albescens* Rothsch. p. p.) (51 c). The largest *Automolis* known; body with appressed white scales and wings thinly scaled white, the latter therefore somewhat transparent and with a faint bluish-green reflection. Guiana.
- albescens*. **A. albescens** Rothsch. (50 h). Unicolorously milky white, body and wings. Not quite half the size of *leucoptera*. Surinam.
- noira*. **A. noira** Jones (50 h). Likewise white, but the thorax finely marked rosy-red, forewing with a yellowish costal stripe, darker veins and internerval streaks in and below the cell. Santos (South Brazil).
- surinamensis*. **A. surinamensis** Rothsch. (50 h). White, body and forewings bone-white, hindwings milky-white; forelegs inside purple. Much larger than *noira*. Surinam.
- schausi*. **A. schausi** Rothsch. (50 h). All the wings pale yellow, thorax light yellow with 2 dots on the tegulae and a black spot between the patagia. Abdomen black with a broad, orange-yellow belt, on which there is a black spot. Costa Rica.
- elissa*. **A. elissa** Schs. (50 i) is very much like *schausi*, somewhat smaller, of a lighter colouring, thorax without spots, the black of the apex of the abdomen only above, whereas beneath the whole venter is orange. Venezuela, Brazil and Bolivia (Rio Songo).
- pseudelissa*. **A. pseudelissa** Dgn. (50 i) from Venezuela, Peru and Bolivia is exceedingly similar to the preceding, but across the mesothorax, between the patagia, a black streak, and the abdomen at the end not black, but yellow with small black transverse spots and with punctiform lateral spots.
- elissoides*. **A. elissoides** Rothsch. is almost exactly like the preceding, only paler, more bone-white than pale yellow, but beneath easily recognized by the chest being orange-yellow, whereas *pseudelissa* has a blackish chest and only orange-yellow anterior hips. Venezuela, Trinidad, and Bolivia.
- ventralis*. **A. ventralis** Schs. (50 i). Size, shape and colour of wings like in the preceding, but the forewing at the base black, and bordered with black at the costa and anal angle. Besides the body is above black except the creamy-white tegulae and patagia, beneath, however, orange. Colombia (Villavicencio) and Venezuela.
- tripunctata*. **A. tripunctata** Drc. (50 h) is much smaller than the preceding; pale yellow, head, and collar yolk-coloured, forewing with black, lustrous blue spots at the base, anal angle and between the radials. A dark costal streak proceeds from the base and cuts off the apical part. Panama.
- brachystriata*. **A. brachystriata** Dgn. (50 i). White, somewhat opalescent, abdomen banded red; round the cell-end of the forewing small dark punctiform spots, one near the base and one between the cell-end and border; short, golden brown transverse streaks on the median veins, the submedian, and between in the submedian space. Hindwings entirely white. Colombia.
- aleteria*. **A. aleteria** Schs. (50 i) resembles the preceding; abdomen above except apex and base quite red, spotted whitish; forewing without dark dots before and behind the transverse vein, the yellowish-brown streak-spots in the disc longer, the ♂ with a round sexual spot at the costa of the hindwing. French Guiana.
- aletis*. **A. aletis** Schs. (50 i). Thoracic dorsum with 4 dark dots, ♂ with prominent brown streaks round the cell-end and a small punctiform streak far behind them; ♀ with a double row of streaks in the submedian space and below it. Costa Rica and Panama.

A. idalia *Hmps.* (50 i). Abdominal dorsum quite red except the base and apex. Forewing without *idalia*, spots round the cell-end, but with a broad, brown costal margin and groups of streak-spots at the base and above the anal angle. Wings tinted pink. Rio de Janeiro.

A. crinis *Dre.* (52 a). White, thorax and head orange and spotted red. Through the middle of the *crinis*, forewing runs a small, greyish-yellow transverse band being on both sides distinctly, though irregularly, bordered with black. Before the distal margin a small black streak and almost invariably 2 or 3 distinct black parallel streaks above the proximal margin; also at the base some marking. Mexico and Central America; in some places common.

A. metacrinis *Rothsch.* (52 a). Similar, larger; the small transverse band of black transverse lines is *metacrinis*, replaced by a series of brown internerval spots from the costa to the middle of the proximal margin. Otherwise the wings are white except some small basal streaks. Colombia, Ecuador.

A. tenuifascia *Dgn.* (50 k) from Colombia is quite similar, but the abdomen only at the base red, *tenuifascia*, thorax unspotted. At the base of the forewing 4 long streaks, the small transverse band is only a row of punctiform spots and bordered with black only at the cell-end, before and behind it the wing is tinted ochreous-yellow. Colombia.

A. delicata *Möschl.* (50 k) is quite similar, the size of *crinis*. Abdomen purple red with white dorsal *delicata*, dots. Forewing with a grey basal spot striped black, below it a pink inner-marginal spot. In the cell-end and below the middle of the cell a yellow spot, through the middle of the wing a narrow grey oblique band exhibiting transverse streaks at the costa and above the proximal margin, with a black border at the cell-end. Jamaica.

A. pichesensis *Dyar* (52 a). Dorsum of abdomen red, thorax variegated. Forewing with a violettish- *pichesensis*, grey basal quarter finely traversed by the veins, the transverse band somewhat curved, the wing before and behind it slightly tinged yellowish. Peru.

A. crithéis *Dre.* (50 k). Thorax spotted yellow, abdomen red with traces of rows of white dots. Fore- *crithéis*, wings yellowish, the basal spot extending almost equally far at the costa and proximal margin, traversed by the veins, bordered with white, the transverse macular band proximally convex. Panama, Brazil.

A. herois *Schs.* (50 k). Somewhat smaller, the basal spot of the forewing extends at the proximal *herois*, margin farther than at the costal margin and encloses a pink inner-marginal spot. The small transverse band has the proximal border almost straight, the distal border very convex. Mexico, Venezuela, South Brazil. — **iragorri** *Dgn.* are specimens from Venezuela, Ecuador and Brazil, chiefly distinguished by their larger size *iragorri*, and the rounder shape of the ♂ hindwing.

A. ochracea *Rothsch.* (50 k) is quite similar, but the transverse band duller and the basal spot of the *ochracea*, forewing forms a wreath of short rays reaching the costa only with a dot, extending, however, at the proximal margin, where it encloses a yellow basal spot, almost to the middle. Abdomen ochreous yellow. — **dorsalis** *dorsalis*, *form. nov.* (50 k), perhaps a distinct species, shows the transverse band distinct, also the rays at the base growing shorter towards the costa, but the abdomen is hemochrome. On the forewing the yellow tinge of the median area reaches neither the costa nor the proximal margin. Central Colombia (Villavicencio, discovered by FASSL).

A. decisa *Rothsch.* (50 k) is larger than the preceding, easily recognized by the thicker, somewhat *decisa*, irregular spot at the transverse band through the middle of the forewing. Guiana.

A. dognini *Rothsch.* (52 a) is quite similar to *decisa*, but the transverse band straighter, the thorax *dognini*, marked red and the basal spot in the inner-marginal half only yet represented by a dot above the proximal margin before its middle. Peru.

A. monostidza *Hmps.* (52 a) is very closely allied to *dognini*, but between the cell-end and the border *monostidza*, of the forewing there is yet a black, oblong dot. Peru.

A. carinosa *Schs.* (51 a). Transverse band and basal spot scarcely appreciably and very finely crossed *carinosa*, by the light veins, whereby both appear darker and more intense. Base of proximal margin bright red. Rio de Janeiro.

A. ochreata *Schs.* (52 a), from Guiana, has yellow wings, the centre of the forewing of a deeper colour, *ochreata*, and an ochreous-yellow abdomen. The very broad transverse band approaches at the proximal margin very much the dark basal band. Beneath both wings show a scent-fur in the disc.

A. luteorosea *Rothsch.* (52 a). The transverse band of the forewing still much broader than in the *luteorosea*, preceding, forewings otherwise yellowish. Hindwings and abdomen purple-pink. Guiana.

A. multicolor *Rothsch.* (52 a). Marking almost like in *luteorosea*, but the ground-colour of the forewings *multicolor*, dark brownish-yellow. At the costa of the forewing 2 white patches representing the beginning of the white border defining the transverse band and basal spot in the allied species. Guiana.

A. ditissimus *Dre.* (51 a) is unlike the *Automolis* owing to its slender body as well as to the relatively *ditissimus*, long wings; also the marking of this and the 2 or 3 next species deviates from all the other *Automolis* by the

resemblance to numerous *Neritos*, *Paranerita* etc. Forewings brown, marked red, along the border and costa a yellow band, the latter in the middle of the cell broadest. Abdomen and hindwing dark brown. A small species; Panama, Amazon, South Brazil.

chrysopera. **A. chrysopera** Schs. (51 a) is still smaller, the costa marked red, not yellow, at the border irregular, orange-yellow spots. Hindwings in the basal half pink, distal half black. Guiana.

pulverosa. **A. pulverosa** Schs. Thorax white, marked yellowish-brown, abdomen above orange, beneath white. Forewing pale brown with white streaks on the veins in the marginal area or small white dots. Near the base a white transverse streak, also the transverse vein white, round the lower cell-angle brownish shading; postmedian line white, incomplete. Hindwing diaphanous white, in the middle of the border tinged brownish. Size of *fassli* (50 g). Surinam.

neritosia. **A. neritosia** Jones is very little larger than *ditissimus* (51 a); forewing pale red-brown with a large pale yellow distal spot, the border of which extends from the anal angle to the cell-end, from there below the costa distally and making below the apical part a small, downward convex bow. Abdomen red, hindwings pale yellow. South Brazil (São Paulo).

semirosea. **A. semirosea** Wkr. (51 b) is still smaller than *neritosia*, the light yellow distal spot proximally irregularly defined, a second, conical spot on the submedian. Hindwing light pink, at the proximal margin darker. Amazon (Teffé).

perflua. **A. perflua** Wkr. (51 a) is much larger than the preceding. Forewings violettish-brown; large yellow spots at the base, middle of proximal margin and at the border, smaller ones in the ♂ round the cell-end; hindwings in the ♂ deep pink, in the ♀ browner. Rio de Janeiro.

juvenis. **A. juvenis** Schs. (51 a). Very dimorphous; particularly the ♂ repeats the colourings of numerous *Amaxia*, *Neritos*, *Paranerita*, *Neaxia* etc. A violettish-red proximal part of the forewing, resting broadly on the proximal margin, but leaving free the costa, is in a dentate incision defined towards the light yellow apical half which shows rows of fine dots and small rings and large spots marked red before the apex. In the ♀ the violettish-red basal part is very much mixed with yellow, and the preapical spots are connected with the brown at the proximal margin by an oblique chain of spots parallel to the border and more or less complete. Mexico, apparently not rare.

divisus. **A. divisus** H.-Schäff. (= *marcapata* Drc.) (46 l). Purple red, forewing at the base with a white dot. From the middle of the cell 2 curved, dark lines proceed; marginal area pale yellow with a purple apical spot; hindwing in the costal half hyaline, in the proximal half red. The ♀ has a hyaline spot encircled by red from the costa to the 1st median vein, hindwings light rosy-red. Size of *juvenis*. Peru *).

ilioides. **A. ilioides** Schs. (51 a) resembles some *Carathis* in the colouring (comp. p. 335); forewing light yellow with brown spots along the proximal margin and border, and marked with dark rings in the disc. Hindwing diaphanous white, at the proximal margin pink; abdomen orange. Guiana.

ilus. **A. ilus** Cr. (51 b) is larger (50 mm), the shape recalling *Halisidota*. In the whole forewing, except the apical quarter, the dark brown colour is preponderant, the yellow being interspersed in differently shaped small spots near the base, at the costa, and before the border. The small rings marked much smaller than in *ilioides*. Hindwing and dorsum of abdomen purple pink. Guiana, Colombia, and in a great part of Brazil.

formona. **A. formona** Schs. (51 b). Forewing pale yellow, in the disc dispersed dark markings, the veins red. A dark stripe extends from the base of the forewing to the anal angle, and a postmedian, densely dotted, dark line parallel to the border. Hindwings pink; abdomen above purple. Guiana. — This species also resembles a *Halisidota*.

baritioides. **A. baritioides** Roths. (51 b) is much smaller; on the forewing the pale yellow ground-colour is almost entirely covered by red shades, tinges, margins, and vein-streaks. Body and hindwings purple pink, the latter at the costal margin lighter. Amazon.

ignivena. **A. ignivena** Joicey (53 f). Size of *juvenis*-♀ (51 a). Forewing light red-brown, cell and the space behind it tinged dark brown, with which the brown of the marginal half of the proximal area is connected; veins red, red markings in the cell and disc; marginal half pale yellow; hindwings dark brown; abdominal dorsum purple. Peru; founded upon 1 ♀.

citrina. **A. citrina** Drc. (51 b). Forewing bright yellow with a red streak-spot from the base and above the proximal margin at the anal angle, above both red streaks grey markings; at the cell-end a small, greyish-red band, a minute ring-spot before the apical part. Hindwings white, abdominal dorsum purple. Venezuela and South Brazil.

rosa. **A. rosa** Drc. (51 b). Larger; forewing lemon-coloured with a purple cloudy spot below the cell, a red transverse spot at the cell-end and a red, curved, above broad postmedian band; hindwings white, body yellow. Colombia.

* The position is doubtful; p. 363 by mistake denominated as *Antaxia dichroma*, by HERRICH-SCHAEFFER at first as *Cretonotus*, then as *Echeta*. Nor did DRUCE recognize it, and placed it as *marcapata* to *Automolis*, in spite of the venation of the hindwing. The paragraph on p. 363 is therefore to be eliminated.

A. juno Schs. Forewings ochreous-yellow, suffused with greyish-brown. Below the cell a white spot *juno*. near the base, an antemedian yellow band bordered with red, at the cell-end a feeble purple spot, in the distal part yellow spots bordered with red in a curved row as far as beyond the proximal margin, between the radial veins 3 yellow, diaphanous moon-spots, behind them a row of 5 similar spots and a row of yellow antemarginal spots. Hindwing pink, in and below the cell yellow streaks, also the fringes yellow. The ♀ has before the apical area of the forewing a small vitreous spot, but no yellow spots behind it; the antemarginal spots mostly smaller. Size of the preceding. Guiana and South Brazil.

A. rubrireta Dgn. (51 b, c) is larger than the preceding, particularly the ♀. In the ♂ the forewing is *rubrireta*. *rubr*coloured with red dentate lines, a costal stripe and a stripe across the cell-end to the anal angle dark brown; the ♀ has quite brown forewings in which the yellow ground-colour appears only yet in single, small, round spots. Hindwing yellowish pink, the part round the cell lighter. — **rhodocyma** Dgn. (51 c) is presumably only *rhodocyma*. a form of this species, in which the dark brown postmedian band is interrupted and its lower part bent down towards the border. — **brunneireta** Dgn. (51 d) are ♂♂ in which the dark brown of the forewing is almost as *brunneireta*. expanded as in *rubrireta*-♀. — To this the form **rhodographa** Dgn. (51 d) may belong as the ♀, deviating from *rhodogra-* the *rubrireta*-♀ by the darkened yellow spots of the forewing and by the hindwings being uniformly brownish. — *pha*. Peru.

A. flammans Hmps. (51 d). A magnificent, purple-brown, large butterfly tinged rosy, with an irre- *flammans*. regularly shaped, discal vitreous spot dotted purple, and silvery white spots near the base, at the costal margin and border. Hindwings diaphanous white, at the costal and proximal margins broadly pinkish-brown. Colombia, apparently rare; before me only ♂♂ from the malarious village of Muzo.

A. subflammans Roths. (51 d) is a closely allied form, somewhat smaller, the dotted vitreous spot *subflam-* of the forewing more band-shaped and more remote from the border. South Brazil and Bolivia (the figured *mans*. specimen from the Rio Songo). It might be the southern form of *flammans*, but the latter is reported to have been found also in Santa Catharina. — **fulminans** Roths. (51 d) is perhaps only the ♀ of it or of a very closely *fulminans*. allied form, distinguished by the absence of the marginal spots and a smaller discal spot and by the absence of the black dorsal dots on the abdomen. South Brazil.

A. perflammans Dgn. (51 e) is much smaller than *flammans* and has a much smaller discal spot and *perflam-* very small marginal spots. From Guiana. *mans*.

A. grandis Drc. (51 c). Next to the white *leucoptera* the largest *Automolis*. Forewings purple-brown, *grandis*. in the disc 5 oval vitreous spots, the costal one being the smallest, and in the cell a hyaline triangle. ♂ hindwing yellowish, towards the base tinged pink, costal area diaphanous. Bolivia (Rio Songo) and Ecuador.

A. sanguinolenta Cr. (51 e) is quite ruddle-red, suffused with purple, between the cell-end and border *sanguino-* in the forewing a small, oblong vitreous spot, a violet ante- and a postmedian stripe meet before the middle *lenta*. of the proximal margin and enclose an orange-red layer encircled by purple; hindwings purple-pink; Surinam, Bolivia. — **justina** Cr., before me from Villavicencio (Coll. FASSL), is smaller, the postcellular vitreous spot *justina*. is rounder and the violet oblique transverse stripes are more separated. — **cruenta** Roths. (51 e) is still *cruenta*. smaller, the vitreous spot of the forewing round, the hindwings quite diaphanous, only at the border of a brighter pink. — The larva deviates so much from the other *Automolis*-larvae known, that the insertion in this genus is scarcely maintainable. It lives on the Papaya-tree, is quite uniformly densely covered with very fine, whitish hair on dark tubercles, without any pencils or brushes, the colour at first reddish-yellow, in the grown-up state above black, only the venter and sides being yet red.

A. buckleyi Drc. from Ecuador differs from the figured **harterti** Roths. (51 e) by more uniformly *buckleyi*. orange-red colouring. *harterti* comes from the Amazon (Fonte Boa) and Colombia; we figure it from Muzo. — **whitfordi** Roths. is quite similar, but the proximal half of the forewing is quite vermilion, and the black *whitfordi*. lines bordering on the bone-coloured costal and basal spots, are more intense; from Guiana.

A. garleppi Dr. (= *mirabilior* Dyar) (51 e) resembles the preceding, of a bright vermilion with rosy- *garleppi*. red hindwings, the whitish-yellow costal spots of the forewings smaller; above the anal angle there is yet a large, oval, grey spot; from Peru and Bolivia. — **inversa** Roths. (51 e) from Peru connects this species with *inversa*. the preceding, for the bone-coloured costal spots are as large as there, and the grey spot above the anal angle of the forewing is not even half as large as in typical *garleppi*, though still larger than in *buckleyi*. — In **maronensis** Roths. the grey anal-angular spot is not quite so small as in *inversa*, but still smaller than in *maronensis*. typical *garleppi*; from Guiana. — **pallidipennis** LORD ROTHSCILD denominates specimens from Fonte Boa, *pallidipen-* where the hindwings are only tinged scarlet at the inner-marginal area, otherwise they are diaphanous of a *nis*. buff colour. — The assertion that *buckleyi* and *garleppi* are separate species can be hardly upheld.

A. docis Hbn. (= *basalis* Wkr.) (51 f) is a still more variable form than the preceding. The type *docis*. has a black head and body, an orange-red stripe on the patagia, on the abdomen a red-yellow saddle-spot and behind it lustrous blue dots; forewing with a red stripe angled at the cell-end, extending from near the base of the proximal margin to below the apex, sending a thick branch from the cell-end towards the costal margin.

- Hindwing with red at the base and cell. This is, however, not always the exterior of the butterfly; the stripe on the forewing may be reduced to traces and even disappear altogether, just like the basal red of the hindwing. I denominate this form having already been figured by LORD ROTHSCILD, in its extremest development, ab. *tenebrata*. ***tenebrata* nom. nov.** (51 f). On the contrary, the yellow stripe on the forewing and the basal red of the hindwing may be widened to such an extent that only the margins of the wings remain yet black; this form having likewise been already ascertained by LORD ROTHSCILD I denominate ab. ***laeta* nom. nov.** (51 f). Between these extreme forms all transitions imaginable seem to occur: among them also such approximating species from the *taeniata*- and *maura*-group by the widened stripes of the forewings. I figure *docis* from Villavicencio in Colombia; it occurs besides in Guiana and the Amazon District; the colorial varieties, however, are not bound to localities.
- crocopera*. ***A. crocopera* Schs.** This species is easily recognized by the deeply indented border of the hindwing. It is but very little larger than *docis*, but it has more slender wings. The forewings are unicolorously dull greyish-green, the hindwings blackish-blue with a hyaline centre; head orange, thorax brownish-green, abdomen blackish-blue, the 3 last rings orange. Guiana. Apparently only the type is known, one ♂ in the Museum at Washington.
- inexpectata*. ***A. inexpectata* Rothsch.** (51 g) is larger, though similarly shaped as *docis*. Head, thorax and abdominal end orange, dorsum otherwise black with a very faint greyish-blue reflection. Forewing mostly diaphanous whitish, darkened by brown; at the base, costa, cell-end, and in the apical third sepia-brown layers. Venezuela, Colombia and Peru; the figured specimen from Muzo.
- lutosa*. ***A. lutosa* Hbn.** Almost quite greyish-brown, forewing with a light postcellular macular band as far as the upper median; hindwing in the middle yellowish-brown with traces of a light postmedian band. Paraguay.
- linaza*. Typical specimens also show a broad, faded, white band in the forewing, which is absent in the form ***linaza* Dgn.** Body yellowish-red.
- dissimilis*. ***A. dissimilis* Drc.** (51 g) is still larger than the preceding; in the shape more like an *Amastus* or a large *Halisidota*. Wings dull creamy-white with yellowish-brown veins, the forewing darkened cloudily in the apical part and with a brown crescentiform shade at the cell-end. Thorax whitish with orange stripes in the middle, on the collar and patagia; abdomen dark brown with orange bands and spots, beneath and below yolk-coloured. Peru.
- soror*. ***A. soror* Rothsch.** (51 g). Size of *dissimilis*. Forewing dark nut-brown, hindwing with a white, distally and costally darkened demi-band behind the darker cell-end, hindwing in and behind the cell lighter, yellowish-grey. Head and body orange. Amazon.
- felderi*. ***A. felderi* Rothsch.** (51 g). Much smaller, about the size of *docis*. Forewing somewhat lighter brown than *soror*, the white postcellular cloud not band-shaped but reniform, lessening distally. Hindwings and body light greyish-yellow. Colombia.
- sordidipennis*. ***A. sordidipennis* Rothsch.** (51 g). Wings dark greyish-brown, forewing with a light centre. Body blackish, tegulae, patagia, and abdominal end bright yellow. Venezuela.
- stenotis*. ***A. stenotis* Dgn.** (51 g). Much smaller than *sordidipennis*. Forewings and thorax dark brown, hindwings whitish, head and collar tinged in a yolk-colour. Guiana.
- fuliginosa*. ***A. fuliginosa* Rothsch.** (51 g). Deep sooty black, margins darker, the disc somewhat lighter; at the proximal margin of the hindwing a white spot. Body black with minute white spots on tegulae, metanotum and middle of abdomen. Fonte Boa (Amazon).
- uniformis*. ***A. uniformis* Rothsch.** (51 h). Forewing dark greyish-brown with light veins, hindwing blackish-brown, in the basal half lighter grey; beneath this lighter patch is chalky-white. Head orange; middle of abdomen with a yellow longitudinal spot, like the venter. Described from Surinam, but before me only from Colombia (Villavicencio). — In the Bolivian form from the Rio Songo, ab. ***mesoleuca* form. nov.** (51 h), the centre of the hindwing is also above white; transitions to the typical form are not rare.
- separata*. ***A. separata* Wkr.** (51 h) is somewhat larger than *uniformis*, forewings like there, but the hindwing with an orange-yellow proximal half, and the abdomen with a broad yellow belt. Colombia and Amazon.
- priscilla*. ***A. priscilla* Schs.** (51 h). Forewing with a large, bone-coloured, sacciform spot behind the middle of the costa. Hindwing yellow, only along the middle of the border a dark band. Abdomen with a yellow belt. Costa Rica.
- persimilis*. ***A. persimilis* Rothsch.** (51 h). Smaller, the sacciform costal spot in the forewing yellow, beneath more pointed. Hindwing small, in typical specimens as we figure from Bolivia, but as they also occur in Peru, quite unicolorously yellow. — ***marginata* Rothsch.** (51 h) has on the forewing much brighter, almost white veins,

and in the hindwing a marginal band being broader in the ♂. Costa Rica; in Amazon specimens only the costal-marginal part of the hindwing is yellow. — Abdomen always with a yellow belt.

A. strigosa Wkr. (51 h). Black, forewing in the distal half with long, dull whitish-grey longitudinal spots, behind the cell-end a long snow-white spot; hindwing with a whitish diaphanous centre. Patagia with a white centre, dorsum of abdomen with a yellow lateral spot divided by a dark tinge. Panama, Colombia, Brazil. — In the ♀ (= subulifera Fldr.) the light longitudinal spots are shorter, broader, more oval. Apparently rare.

A. albiplaga Schs. (51 h) is black with a white, round postcellular spot on the forewing and a white centre of the hindwing; patagial apex white; dorsum of abdomen with an orange lateral spot. Guiana and South Brazil.

A. chionoplaga Dgn. (51 i) is much larger than *albiplaga*; forewing with a large, white postmedian disc; hindwing with a whitish centre. Head yellow, abdomen with a red belt. Panama.

A. niveomaculata Roths. (51 i). Like the preceding, but the wings of a much duller colouring, on the veins and in the innermarginal area and submedian space of the forewing white, dorsum of abdomen with a yellow lateral spot. From Peru and the Upper Rio Negro (Colombia). — **leucoplaga** Dgn. (51 i) has a larger disc of the forewing, the white vein-stripes in the inner-marginal area are almost confluent, and the hindwings are quite white except a narrow margin. Described from the Chanchamayo in Peru, the figured specimen, however, also originates from Colombia.

A. dolens Drc. (52 b). Blackish-brown, forewing with a white antemedian transverse band and apical oblique band, from the exit of which the border is white as far as the anal angle, the basal half of the hindwing being also white. Tegulae and patagia white, the ring at the abdominal base yellow. South Brazil (Castro) and Paraguay.

A. zonana Schs. (51 i) is quite similar, but above the anal angle on the border a sacciform, whitish-yellow spot, the border otherwise not white; — in ab. **incompleta** ab. nov. (52 b) the sacciform spot is absent altogether or only traces left of it. Guiana and Bolivia.

A. moma Schs. (51 i) resembles the two preceding, but the bands of the forewings are lemon-coloured, the apical one steeper, the antemedian one in typical specimens very broad, in the form **tenuifascia** Roths. (from South Brazil) narrow. Collar broad lemon-coloured; abdomen, however, at the base not white, but with a postmedian orange ring being broad in the ♂. Guiana, Venezuela, Colombia and Bolivia.

A. angulosa Wkr. (= flavicinctus H.-Schäff.) (52 b). Marking of the preceding, but the bands of the forewings and the collar orange, and instead of the orange belt before the end of the abdomen, the base of the abdomen is here dark yellow. In the typical form from Colombia and Brazil the bands of the forewing are quite narrow, as in *moma tenuifascia*, in **griseonitens** Roths. (52 b) from Bolivia and Peru they are much broader, and in **ardesiaca** Roths. (52 b) from Guiana to Venezuela the ground-colour of the forewings is bleached to a dull brownish-grey.

A. schistaceus Roths. (52 b) is like *angulosa*, but the forewing without the band in the apical part. Venezuela.

A. tegyra Drc. (52 c). Bands of forewings yellow, the posterior one being steeper and angled behind the cell; the abdomen except the black apex quite golden yellow. From the Chiriqui in Panama.

A. gyrata Schs. from Guatemala is entirely like *tegyra*, but the basal half of the abdomen above black.

A. rectiradia Hmps. (52 b). The light bands of the forewings more blurred, the posterior one only in the costal part, separated from the dark greyish-brown inner-marginal area by a light longitudinal ray through the middle of the forewing. Also on the hindwing there is a dark brown margin, but no sharply defined marginal band. Head, collar and patagia bone-white, marked pink, abdomen on both sides black. Surinam, Amazon, and Colombia.

A. catharinae Roths. (52 b). Similar to *rectiradia*, larger, the proximal band of the forewing at the proximal margin quite narrow, the distal transverse band absent, instead of it along the costa a yellow stripe. South Brazil: Santa Catharina, Organ Mountains.

A. diluta Fldr. (52 c). Here the yellow transverse bands of the preceding are altogether absent; dark dusty-grey, costal margin of the forewing broad sulphureous; near the base a small dark transverse band, along the median faintly lighter. On the under surface also the base of the hindwing is sulphureous. Mexico, Central America, Pará.

A. vampa Schs. (52 c), much smaller than the preceding, quite ochreous-yellow; forewing with a dark cell-end dot, blackish veins in the apical part and a yellowish-brown band beginning broad before the middle of the costa and terminating much narrower into the border above the anal angle. Costa Rica.

A. polystria Schs. (52 c) is quite similar, of a paler yellow, the vein-streaks in the apical part of the forewing shorter, but stronger, also in the brown oblique band of the forewing distinct, black streaks. Guiana.

A. vittipes Drc. (52 c). Pale ochreous-yellow, the forewing with black parallel rays above, in below the cell, growing shorter towards the proximal margin; another pencil of parallel rays goes through the middle of the marginal area. In typical specimens the dorsum of the abdomen is purple-red, and the yellow of the forewing has a reddish tone. Such specimens occur on the volcano Chiriqui in Panama, and in Muzo

in Colombia. Specimens from the Rio Songo in Bolivia have scarcely yet the red tinge on the abdomen, and in such from the Upper Rio Negro and Villavicencio the forewings and abdominal dorsum are decidedly yellow; *vitellina*. I denominate the latter *vitellina form. nov.* (52 c); they are smaller than typical *vittipes*.

internervosa. **A. internervosa** Dgn. (52 c). Scarcely larger than *vittipes*, wings pale yellow, forewing with fine black veins and streaks between them; body yolk-coloured, thorax dotted black. Colombia (Medina).

erythronotus. **A. erythronotus** H.-Schäff. (52 c). Forewing pale yellowish, almost hyaline with black veins, the transverse vein bordered with black, and a black streak in the submedian space terminating an oval, chalky-white longitudinal spot. Hindwings white, abdomen above hemochrome, at the base and apex white. Colombia, Venezuela.

lineosa. **A. lineosa** Wkr. (= *erythronota* Drc. nec H.-Schäff., ♀ = *perlineosa* Rothsch.) (52 d). Smaller, the vein-streaks shorter, not joining each other. Particularly behind the cell-end a large, hyaline spot is produced by the base of the radials remaining uncoloured. In typical specimens, as we figure them from Colombia (Rio Negro), but as they also occur in Costa Rica, there are in the distal area, cell and submedian space chrome-yellow longitudinal, diffuse spots embedded between the black vein-streaks. — In *sublineata* Rothsch. (52 d) from Peru they are absent, and the radial veins are streaked dark as far as near the transverse vein.

dilucida. **A. dilucida** Rothsch. (52 d). Forewing diaphanous white, of the black longitudinal streaks only the beginnings are yet visible in the costal and basal parts, and the ends (at the border, and besides the border of the transverse vein. Thorax in some places and abdomen above tinged purple-pink. Peru.

vinasia. **A. vinasia** Schs. Forewing brown, apical area yellow from the costa above the cell-end to the upper median vein, below which there is a short yellow oblique streak. Proximal border of this yellow area irregular; between the radial veins the brown ground-colour projects towards the margin. Veins delicately streaked light; round the base of the wing faint light dots; from the lower cell-angle a deeply dentate chain of white small crescents to the middle of the proximal margin. Hindwings brown, towards the costa whitish. Head and thorax whitish, tinged brown, abdomen above purple-red. Costa Rica. The type in the Museum of Washington. Size of *A. bonora* (50 g).

turidoides. **A. luridoides** Rothsch. (52 d). Pale yellow, light bluish-grey oval spots are between the patagia on the mesothorax, near the base of the forewing, obliquely through the middle of the forewing and before the apex of the forewing; the 3 oval spots on the wings are encircled by white. Minas Geraes (Brazil).

turida. **A. lurida** Fldr. (52 d). The spots are arranged like in the preceding, but the one at the base of the forewing is small, that in the middle very large, the preapical one circular. Colombia (Rio Negro) and Peru.

pseudoflavescens. **A. pseudoflavescens** Rothsch. (52 d). Smaller, only one large, round, grey spot on the disc of the forewing. Hindwing greyish, dorsum of abdomen sooty black, apex yellow. Minas Geraes (Brazil).

aureogrisea. **A. aureogrisea** Rothsch. (52 d). Yellow, the large, greyish-violet spot on the forewing occupies almost the whole inner-marginal half of the forewing. Abdominal dorsum likewise dull yolk-coloured. Peru.

flavescens. **A. flavescens** Wkr. (52 d). The violettish-grey spot on the forewing forms a horse-shoe-like arch over the proximal margin of the forewing and is not so sharply defined as in *aureogrisea*. Amazon and Bolivia. A specimen from Colombia (Rio Negro) is much paler than the specimens before me from the Rio Songo, but also rather much flown, so that the difference may be only individual.

asara. **A. asara** Drc. Likewise from Ecuador, is so closely allied to *flavescens*, that it was formerly included with it as synonymous; here the violettish-grey arcuate shade begins to break up into 3 spots; one before the anal angle, a large cloud in the disc and a third spot above the proximal margin near the base.

reducta. **A. reducta** Wkr. (= *lobifer* H.-Schäff., incerta Drc.) (52 e). Easily recognizable by the distorted hindwing of the ♂, the proximal margin of which terminates into a long lobe exhibiting a scent-fur. Pale yellow, a violet costal stripe from the base to the middle of the wing, and an oblique nebulous stripe from the apex as far as behind the middle of the proximal margin. Panama and South Brazil (Rio de Janeiro).

larissa. **A. larissa** Drc. (52 e). Forewing hyaline, a brown stripe along the costal margin, from which right behind the base a thick branch runs towards the anal angle. Abdomen above hemochrome. On the under surface the brown stripes of the forewing are absent. Colombia and Amazon.

unifascia. **A. unifascia** Drc. (52 c). A very variable animal, the forms of which, however, are scarcely to be separated geographically. Forewing milky-white with a black oblique and inner-marginal band, meeting each other at the anal angle. Hindwing with a broad black proximal margin. Guiana. — In *borussica form. nov.* (52 e) from the Rio Songo in Bolivia also the apex of the forewing is black and in *alboatra* Rothsch. (52 e) from Guiana, the Amazon and Peru also the costa, apex, and distal margin of the hindwing are blackened. — On the contrary, *hamifera* Dgn. (52 e) from French Guiana has the black colour reduced, the transverse band of the forewing showing a break, and in *apicata* Schs. (52 f), likewise from French Guiana, only the apex of the forewing

and a double inner-marginal stripe of the forewing are yet black. Otherwise the wings are quite white. — In all these forms the body is above brownish-black, head and abdominal end orange, marked black, patagia white.

A. klagesi *Rothsch.* (52 e). Black, forewing with a yellow transverse band, hindwing with a white *klagesi* centre; abdomen laterally spotted yellow. Fonte Boa on the Amazon.

A. ockendeni *Rothsch.* (52 e). Like the preceding, but the band of the forewing more uniform and *ockendeni* more oblique, hindwing quite black, only at the base of the costa whitish. Abdomen laterally not yellow, Peru. — **A. lativitta** *Rothsch.*, from Fonte Boa on the Amazon, has a much broader band of the forewing. — This species *lativitta* superficially resembles numerous South American night-butterflies from other groups (Syntomids, Agaristids), even *Rhopalocera*(*Lymnas*) flying in the same districts.

A. apicalis *Wkr.* has the band of the forewing shaped and situate almost exactly like in *klagesi apicalis* (52 e), but the abdomen is posteriorly metallic blue and the hindwings are unicolorous, without the white middle spot. Pará.

A. cingulata *Rothsch.* (52 f). Forewing with white veins and a very broad, yellowish oblique band *cingulata* abdomen with a broad, yellow ring. Ecuador.

A. semicostalis *Rothsch.* (52 f). Veins of the forewings not white, but along the costal margin a white *semicostalis* costal stripe as far as behind the middle of the wing; before the apical part a white oblique band; sides of abdomen yellow. Beneath at the base of the hindwing a white, wedge-shaped spot being distally smoothly cut off. Amazon; Teffé, Fonte Boa.

A. apicella *Strd.* (= *apicalis Rothsch.* nec *Wkr.*, *albiapicalis Hmps.*) (52 f) has a somewhat longer *apicella* white costal-marginal stripe of the forewing than *semicostalis*, and the whole apical third of the forewing is yellowish-white. Bolivia.

A. godmani *Drc.* (= *striata Drc.*) (52 f) has the forewings veined light and almost the whole apical *godmani* half of the forewing is light yellow. Hindwing white with a black border. Costa Rica and Panama.

A. rutila *Stoll* was formerly taken to be the ♀ of *godmani*, but LORD ROTHSCCHILD ascertained the ♀ *rutila* which resembles the ♂. Accordingly, *rutila* is a distinct species, but is very closely allied to *godmani* and differs essentially by the forewing exhibiting only a yellow transverse band, but a dark brown apical part. — According to the larva, the species seems not to belong at all to *Automolis* (it was formerly placed in the *Ischnocampa*). The larva is black and in the hairing it resembles more a *Halisidota*-larva, since it is without brush-shaped hair-bundles, whilst long, yellowish-white pencils project on the anterior and posterior parts. On *Psidium pyrifera*. Guiana and Venezuela as far as Peru.

A. sanguistrigata *Dgn.* (52 f). Much smaller than the preceding, basal half of the forewing purple- *sanguistrigata* brown, apical half pale yellow, costa and border tinged golden-yellow. Hindwings pale yellow, abdomen red. Guiana.

A. sordida *Rothsch.* (52 f) is somewhat larger, forewing in the basal half marked purple, in the apical *sordida* part the veins are red; the pale yellow part of the forewing is comparatively small, only about $\frac{1}{3}$ of the wing. Paraguay, Bolivia and Peru.

A. prumaloides *Rothsch.* (52 f). Smaller than *sordida*, easily distinguishable from the preceding by *prumaloides* a bright purple tinge of the hindwings. It repeats the colourings of numerous *Neaxia*, *Prumala*, *Neritos* etc. from the same district. Amazon (Fonte Boa).

A. submarginalis *Rothsch.* (52 g) is still smaller than the preceding, of an expanse of only 26 mm, *submarginalis* otherwise similarly coloured and marked as *sordida*, but in the pale yellow apical third of the forewing there are violettish-red spots embedded between the cell and apex. Minas Geraes in Brazil.

A. leucopera *Dgn.* (52 g) has a whitish thorax with black dorsal dots and, like the preceding, a *leucopera* crimson dorsum of the abdomen. Forewing dark brown, the apical third white; hindwing blackish-grey. Colombia.

A. tuisana *Schs.* (52 g). Here the apical part of the forewing is white as far as beyond the middle *tuisana* of the wing; the smaller, brown basal half striped dark. Between the radials a small white longitudinal dot. Hindwing whitish, proximal half pink; abdomen except the apex purple. Costa Rica.

A. semiopalina *Fldr.* (52 g). Forewing in the (larger) basal part brown with blackish internerval *semiopalina* streaks; apical third snow-white, between the radials projecting somewhat proximally, hindwings whitish-grey, shaded darker. Thorax white, abdomen above orange. Apparently very widely distributed, from Nicaragua through Guiana and the Amazon District to Bolivia and South Brazil.

A. vitrea *Stoll* (52 g) resembles the preceding, but the dark, very much black-streaked basal area *vitrea* of the forewing is irregularly defined towards the hyaline-white apical part, and particularly in the internerval region finely surrounded by yellow and bordered with a fine black line. Above the anal angle and in the

basal part whitish embeddings. Some black antemarginal dots. Hindwing in the costal and inner-marginal area tinged pink. Abdomen above pink. South and Central Brazil and Bolivia. — **meridionalis** Rothsch. (52 h) is a form from Paraguay with a more yellowish-brown disc of the forewing, intermixed with numerous white clouds. — **occidentalis** Rothsch. from Peru greatly resembles the typical form, but like *meridionalis* it has a yolk-coloured, instead of rosy-red abdominal dorsum. — **borealis** Rothsch. (52 h), finally, from Mexico and Central America, which I figure from Orizaba, has the dark part of the forewing light yellowish-brown, striped jet-black, above slightly intermixed with white. Abdomen above orange; the largest form.

intermedia. **A. intermedia** Rothsch. (52 g) is very much like the preceding, but the dark basal part is very much intermixed with white, and in the hyaline apical part there are again numerous, yellowish-brown dim spots. Between the radials before the border there is an oval brown spot and above the proximal margin there is a thick, dark longitudinal spot extending as far as into the submedian space. Colombia (Villavieja) and Peru.

tybris. **A. tybris** Cr. (52 g). Larger than *intermedia*, through the apical part along the border a yellowish-brown macular band, proximally accompanied by a chain of small crescents. Hindwings dull greyish-yellow, at the proximal margin more yellow. Panama, Demerara.

irregularis. **A. irregularis** Rothsch. (52 h). Only the ♂ is described, according to one specimen from Fonte Boa in the Tring Museum. Immediately recognizable by the border of the forewing being somewhat indented in the middle and by 2 uncommonly large furry scent-spots on the under surface, in the forewing over the whole proximal margin, in the hindwing in the costal area covering almost the whole cell. The colour of the wings is a dark yolk-colour, the hindwings paler, the forewing in the disc somewhat lighter, intermixed with small light spots, those between the radials below the cell and above the anal angle being the most distinct; besides there are also fine, red markings. Hindwings tinged rosy; abdomen red.

pandiona. **A. pandiona** Rothsch. (52 h). This and the following species already greatly approximate the *Zatrephes* and differ from all the *Automolis* by the forewing being angled at the exit of the middle radial. Forewing of *pandiona* purple-brown mixed with smaller and larger spots which are mostly margined by reddish and tinted ochreous, of which, however, one in the cell, a row of 4 or 5 behind the cell-end and 1 below the apex are hyaline. A white spot near the base. Hindwings yellowish-pink, in the ♀ purple-red. Guiana, Bolivia and Peru.

subtruncata. **A. subtruncata** Rothsch. (52 h). Similar to the preceding, larger, in the forewing only 2 spots between the radials are faintly diaphanous and larger, one above them and one below them small, punctiform. The distal half of the forewing, except the yellowish marginal spots, uniformly violet. Hindwing yellowish-pink, towards the base lighter. Described from South Brazil; the figured specimen from the Rio Songo in Bolivia.

excavata. **A. excavata** Schs. (52 h). Still larger than the preceding; forewing uniformly red-brown, little marked, only the two spots between the radial veins and 4 at the border yellowish hyaline; hindwings and abdomen purple, tinted ochreous. Costa Rica.

abdalsan. **A. abdalsan** Schs. from Guatemala has a dark grey thorax with orange stripes across the patagia. Abdomen black, above and laterally with blue metallic spots. Forewing with an orange-yellow longitudinal stripe and ochreous-yellow veins. Hindwing with an orange-yellow costal half 26 mm. Guatemala. (Sphingidea-group.)

goloma. **A. goloma** Schs. Orange-yellow, abdomen posteriorly black with metallic blue spots; forewing yellow, between veins 2 and 5 there are 3 marginal spots sometimes flown together to a marginal band; hindwing with a dark marginal shade. ♂ 37, ♀ 42 mm. Guatemala. (Salma-group.)

obscurata. **A. obscurata** Schs. Quite recently described according to a ♀ from Cayuga, Guatemala. Type in the Museum at Washington. Thorax grey, marked purple, abdomen above purple. Forewing dark brownish-grey, purple streaks at the base, of the costal and proximal margins, in and below the cell, on the submedian and median, the latter as far as the border; yellow shades and spots at the cell and middle of the proximal margin; veins 3 to 6 streaked red; between 6 and 7 a greyish-red postmedian spot; border irregularly yellow; an antemarginal brown spot on vein 7; on the veins small brown marginal spots. Hindwings black. 28 mm. Unknown to me *).

48. Genus: **Zatrephes** Hbn.
